Brief Contents

Volume 1 of *Principles & Practice of Physics* includes Chapters 1–21. Volume 2 of *Principles & Practice of Physics* includes Chapters 22–34.

CHAPTER 1 Foundations 19
CHAPTER 2 Motion in One Dimension 53
CHAPTER 3 Acceleration 86
CHAPTER 4 Momentum 116
CHAPTER 5 Energy 149
CHAPTER 6 Principle of Relativity 176
CHAPTER 7 Interactions 211
CHAPTER 8 Force 246
CHAPTER 9 Work 282
CHAPTER 10 Motion in a Plane 314
CHAPTER 11 Motion in a Circle 351
CHAPTER 12 Torque 388
CHAPTER 13 Gravity 425
CHAPTER 14 Special Relativity 461
CHAPTER 15 Periodic Motion 504
CHAPTER 16 Waves in One Dimension 539
CHAPTER 17 Waves in Two and Three Dimensions 580
CHAPTER 18 Fluids 616
CHAPTER 19 Entropy 664
CHAPTER 20 Energy Transferred Thermally 701
CHAPTER 21 Degradation of Energy 742
CHAPTER 22 Electric Interactions 783
CHAPTER 23 The Electric Field 813
CHAPTER 24 Gauss's Law 845
CHAPTER 25 Work and Energy in Electrostatics 878
CHAPTER 26 Charge Separation and Storage 908
CHAPTER 27 Magnetic Interactions 941
CHAPTER 28 Magnetic Fields of Charged Particles in Motion 976
CHAPTER 29 Changing Magnetic Fields 1011
CHAPTER 30 Changing Electric Fields 1042
CHAPTER 31 Electric Circuits 1079
CHAPTER 32 Electronics 1121
CHAPTER 33 Ray Optics 1164
CHAPTER 34 Wave and Particle Optics 1207

About the Author

Eric Mazur is the Balkanski Professor of Physics and Applied Physics at Harvard University, Area Chair of Applied Physics, and a member of the faculty of Education at the Harvard Graduate School of Education. Dr. Mazur is a renowned scientist and researcher in optical physics and in education research, and a sought-after author and speaker.

Dr. Mazur joined the faculty at Harvard shortly after obtaining his Ph.D. at the University of Leiden in the Netherlands. He was awarded Honorary Doctorates from the École Polytechnique and the University of Montreal, the Universidad Nacional Mayor de San Marcos in Lima, Peru, and the Katholieke Universiteit Leuven in Belgium. Dr. Mazur holds honorary professorships at the Institute of Semiconductor Physics of the Chinese Academy of Sciences in Beijing, the Institute of Laser Engineering at the Beijing University of Technology, the Beijing Normal University, Sichuan University, and Nanjing University of Science and Technology. He is a Member of the Royal Academy of Sciences of the Netherlands and a Member of the Royal Holland Society of Sciences and Humanities. In 2014, Dr. Mazur became the inaugural recipient of the Minerva Prize, and in 2018 he received the inaugural International Flipped Learning Award from the American Academy of Learning Arts and Sciences.

Dr. Mazur has held appointments as Visiting Professor or Distinguished Lecturer at Carnegie Mellon University, the Ohio State University, the Pennsylvania State University, Princeton University, Vanderbilt University, Hong Kong University, the University of Leuven in Belgium, and National Taiwan University in Taiwan, among others. From 2015–2017 Dr. Mazur served as Vice-President, President-Elect, and President of the Optical Society.

In addition to his work in optical physics, Dr. Mazur is interested in education, science policy, outreach, and the public perception of science. In 1990, he began developing Peer instruction, a method for teaching large lecture classes interactively. This teaching method has developed a large following, both nationally and internationally, and has been adopted across many science disciplines.

Dr. Mazur is author or co-author of over 300 scientific publications and holds three dozen patents. He has also written on education and is the author of *Peer Instruction: A User's Manual* (Pearson, 1997), a book that explains how to teach large lecture classes interactively. In 2006, he helped produce the award-winning DVD *Interactive Teaching*. He is the co-founder of Learning Catalytics, a platform for promoting interactive problem solving in the classroom, and of Perusall, the first truly AI-driven social learning platform.

To the Student

Let me tell you a bit about myself.

I always knew exactly what I wanted to do. It just never worked out that way.

When I was seven years old, my grandfather gave me a book about astronomy. Growing up in the Netherlands I became fascinated by the structure of the solar system, the Milky Way, the universe. I remember struggling with the concept of infinite space and asking endless questions without getting satisfactory answers. I developed an early passion for space and space exploration. I knew I was going to be an astronomer. In high school I was good at physics, but when I entered university and had to choose a major, I chose astronomy.

It took only a few months for my romance with the heavens to unravel. Instead of teaching me about the mysteries and structure of the universe, astronomy had been reduced to a mind-numbing web of facts, from declinations and right ascensions to semi-major axes and eccentricities. Disillusioned about astronomy, I switched majors to physics. Physics initially turned out to be no better than astronomy, and I struggled to remain engaged. I managed to make it through my courses, often by rote memorization, but the beauty of science eluded me.

It wasn't until doing research in graduate school that I rediscovered the beauty of science. I knew one thing for sure, though: I was never going to be an academic. I was going to do something useful in my life. Just before obtaining my doctorate, I lined up my dream job working on the development of the compact disc, but I decided to spend one year doing postdoctoral research first.

It was a long year. After my postdoc, I accepted a junior faculty position and started teaching. That's when I discovered that the combination of doing research—uncovering the mysteries of the universe—and teaching—helping others to see the beauty of the universe—is a wonderful combination.

When I started teaching, I did what all teachers did at the time: lecture. It took almost a decade to discover that my award-winning lecturing did for my students exactly what the courses I took in college had done for me: It turned the subject that I was teaching into a collection of facts that my students memorized by rote. Instead of transmitting the beauty of my field, I was essentially regurgitating facts to my students.

When I discovered that my students were not mastering even the most basic principles, I decided to completely change my approach to teaching. Instead of lecturing, I asked students to read my lecture notes at home, and then, in class, I taught by questioning—by asking my students to reflect on concepts, discuss in pairs, and experience their own "aha!" moments.

Over the course of more than twenty years, the lecture notes have evolved into this book. Consider this book to be my best possible "lecturing" to you. But instead of listening to me without having the opportunity to reflect and think, this book will permit you to pause and think; to hopefully experience many "aha!" moments on your own.

I hope this book will help you develop the thinking skills that will make you successful in your career. And remember: your future may be—and likely will be—very different from what you imagine.

I welcome any feedback you have. Feel free to send me email or tweets.

I wrote this book for you.

Eric Mazur

Cambridge, MA

To the Instructor

As you may recall from the first edition of this book, the idea of using conservation principles derived from a conversation with a dear friend and colleague, Albert Altman, professor at the University of Massachusetts, Lowell, who asked me if I was familiar with the approach to physics taken by Ernst Mach.

Mach treats conservation of momentum before discussing the laws of motion. It involves direct experimental observation, which appealed to me. His formulation of mechanics had a profound influence on Einstein. Most physicists never use the concept of force because it relates only to mechanics. It has no role in quantum physics, for example. The conservation principles, however, hold throughout all of physics. In that sense they are much more fundamental than Newton's laws. Furthermore, conservation principles involve only algebra, whereas Newton's second law is a differential equation.

Physics education research has shown that the concept of force, where most physics books begin, is fraught with pitfalls. What's more, after tediously deriving many results using kinematics and dynamics, most physics textbooks show that you can derive the same results from conservation principles in just one or two lines. Why not do the easy way first?

In this edition Principles and Practice of Physics, I start with conservation of both momentum and energy, and later bring in the concept of force. The approach is more unified and modern—the conservation principles are the theme that runs throughout this entire book.

Additional motives for writing this text came from my own teaching. Most textbooks focus on the acquisition of information and on the development of procedural knowledge. This focus comes at the expense of conceptual understanding or the ability to transfer knowledge to a new context. As explained below, I have structured this text to redress that balance. I also have drawn deeply on the results of physics education research, including that of my own research group.

Organization of this book

As I considered the best way to convey the conceptual framework of mechanics, it became clear that the standard curriculum needed rethinking. For example, standard texts are forced to redefine certain concepts more than once—a strategy that we know befuddles students. (Examples are work, the standard definition of which is incompatible with the first law of thermodynamics, and energy, which is redefined when modern physics is discussed.)

Another point that has always bothered me is the arbitrary division between "modern" and "classical" physics. In most texts, the first thirty-odd chapters present physics essentially as it was known at the end of the 19th century; "modern physics" gets tacked on at the end. There's no need for this separation. Our goal should be to explain physics in the way that works best for students, using our full contemporary understanding. All physics is modern!

That is why my table of contents departs from the "standard organization" in the following specific ways.

Emphasis on conservation laws. As mentioned earlier, this book introduces the conservation laws early and treats them the way they should be: as the backbone of physics. The advantages of this shift are many. First, it avoids many of the standard pitfalls related to the concept of force, and it leads naturally to the two-body character of forces and the laws of motion. Second, the conservation laws enable students to solve a wide variety of problems without any calculus. Indeed, for complex systems, the conservation laws are often the natural (or only) way to solve problems. Third, the book deduces the conservation laws from experimental observations, helping to make clear their connection with the world around us. I and several other instructors have tested this approach extensively in our classes and found markedly improved performance on problems involving momentum and energy, with large gains on assessment instruments like the Force Concept Inventory.

Early emphasis on the concept of system. Fundamental to most physical models is the separation of a system from its environment. This separation is so basic that physicists tend to carry it out unconsciously, and traditional texts largely gloss over it. This text introduces the concept in the context of conservation principles and uses it consistently.

Postponement of vectors. Most introductory physics concerns phenomena that take place along one dimension. Problems that involve more than one dimension can be broken down into one-dimensional problems using vectorial notation. So, a solid understanding of physics in one dimension is of fundamental importance. However, by introducing vectors in more than one dimension from the start, standard texts distract the student from the basic concepts of kinematics.

In this book, I develop the complete framework of mechanics for motions and interactions in one dimension. I introduce the second dimension when it is needed, starting with rotational motion. Hence, students can focus on the actual physics early on.

Table 1 Scheduling matrix

Topic	Chapters	Can be inserted after chapter . . .	Chapters that can be omitted without affecting continuity
Mechanics	1–14		6, 13–14
Waves	15–17	12	16–17
Fluids	18	9	
Thermal Physics	19–21	10	21
Electricity & Magnetism	22–30	12 (but 17 is needed for 29–30)	29–30
Circuits	31–32	26 (but 30 is needed for 32)	32
Optics	33–34	17	34

Just-in-time introduction of concepts. Wherever possible, I introduce concepts only when they are necessary. This approach allows students to put ideas into immediate practice, leading to better assimilation.

Integration of modern physics. A survey of syllabi shows that less than half the calculus-based courses in the United States cover modern physics. I have therefore integrated selected "modern" topics throughout the text. For example, special relativity is covered in Chapter 14, at the end of mechanics. Chapter 32, Electronics, includes sections on semiconductors and semiconductor devices. Chapter 34, Wave and Particle Optics, contains sections on quantization and photons.

Modularity. I have written the book in a modular fashion so it can accommodate a variety of curricula (See Table 1, "Scheduling matrix").

The book contains two major parts, Mechanics and Electricity and Magnetism, plus five shorter parts. The two major parts by themselves can support an in-depth two-semester or three-quarter course that presents a complete picture of physics embodying the fundamental ideas of modern physics. Additional parts can be added for a longer or faster-paced course. The five shorter parts are more or less self-contained, although they do build on previous material, so their placement is flexible. Within each part or chapter, more advanced or difficult material is placed at the end.

Pedagogy

This text draws on many models and techniques derived from my own teaching and from physics education research. The following are major themes that I have incorporated throughout.

Separation of conceptual and mathematical frameworks. Each chapter is divided into two parts: Concepts and Quantitative Tools. The first part, Concepts, develops the full conceptual framework of the topic and addresses many of the common questions students have. It concentrates on the underlying ideas and paints the big picture, whenever possible without equations. The second part of the chapter, Quantitative Tools, then develops the mathematical framework.

Deductive approach; focus on ideas before names and equations. To the extent possible, this text develops arguments deductively, starting from observations, rather than stating principles and then "deriving" them. This approach makes the material easier to assimilate for students. In the same vein, this text introduces and explains each idea before giving it a formal name or mathematical definition.

Stronger connection to experiment and experience. Physics stems from observations, and this text is structured so that it can do the same. As much as possible, I develop the material from experimental observations (and preferably those that students can make) rather than assertions. Most chapters use actual data in developing ideas, and new notions are always introduced by going from the specific to the general—whenever possible by interpreting everyday examples.

By contrast, standard texts often introduce laws in their most general form and then show that these laws are consistent with specific (and often highly idealized) cases. Consequently, the world of physics and the "real" world remain two different things in the minds of students.

Addressing physical complications. I also strongly oppose presenting unnatural situations; real life complications must always be confronted head-on. For example, the use of unphysical words like frictionless or massless sends a message to the students that physics is unrealistic or, worse, that the world of physics and the real world are unrelated entities. This can easily be avoided by pointing out that friction or mass may be neglected under certain circumstances and pointing out why this may be done.

Engaging the student. Education is more than just transfer of information. Engaging the student's mind so the information can be assimilated is essential. To this end, the text is written as a dialog between author and reader (often invoking the reader—you—in examples)

and is punctuated by Checkpoints—questions that require the reader to stop and think. The text following a Checkpoint often refers directly to its conclusions. Students will find complete solutions to all the Checkpoints at the back of the book; these solutions are written to emphasize physical reasoning and discovery.

Visualization. Visual representations are central to physics, so I developed each chapter by designing the figures before writing the text. Many figures use multiple representations to help students make connections (for example, a sketch may be combined with a graph and a bar diagram). Also, in accordance with research, the illustration style is spare and simple, putting the emphasis on the ideas and relationships rather than on irrelevant details. The figures do not use perspective unless it is needed, for instance.

Physics for today's student

This new edition focuses on today's physics student who not only learns in the physical classroom but gleans knowledge in a digital environment. The content format is modified for students to actively engage with online content first. The second edition optimizes the delivery of the content by combining both volumes of the first edition (Principles volume and Practice volume) and providing it as one single volume via etext and Mastering Physics in addition to the print book.

Best practices reflect the idea that by engaging with the material before coming to class better prepares students to learn. The new edition provides new pre-lecture videos by both Eric Mazur and his Harvard colleague Greg Kestin (researcher and consultant for NOVA) to help students come to class ready to participate, encourage the understanding of real-world application of physics, and support instructors in building active and relevant classes.

As pointed out earlier, each chapter is divided into two parts. The first part (Concepts) develops the conceptual framework in an accessible way, relying primarily on qualitative descriptions and illustrations. In addition to including Checkpoints, each Concepts section ends with a one-page Self-quiz consisting of qualitative questions. The second part of each chapter (Quantitative Tools) formalizes the ideas developed in the first part in mathematical terms. While concise, it is relatively traditional in nature—teachers should be able to continue to use material developed for earlier courses. To avoid creating the impression that equations are more important than the concepts behind them, no equations are highlighted or boxed. Both parts of the chapters contain worked examples to help students develop problem-solving skills.

At the end of each chapter is a Chapter Summary and a Questions and Problems section. The problems 1) offer a range of levels; 2) include problems relating to client disciplines (life sciences, engineering, chemistry, astronomy, etc.); 3) use the second person as much as possible to draw in the student; and 4) do not spoon-feed the students with information and unnecessary diagrams. The problems are classified into three levels as follows: (•) application of single concept; numerical plug-and-chug; (••) nonobvious application of single concept or application of multiple concepts from current chapter; straightforward numerical or algebraic computation; (•••) application of multiple concepts, possibly spanning multiple chapters. Context-rich problems are designated CR.

Additional material can be found online in Mastering Physics:

1. *Review Questions*. The goal of this section is to allow students to quickly review the corresponding chapter. The questions are straightforward one-liners starting with "what" and "how" (rather than "why" or "what if"). These questions are in Mastering Physics.
2. *Developing a Feel*. The goals of this section are to develop a quantitative feel for the quantities introduced in the chapter; to connect the subject of the chapter to the real world; to train students in making estimates and assumptions; to bolster students' confidence in dealing with unfamiliar material. It can be used for self-study or for a homework or recitation assignment. This section, which has no equivalent in existing books, combines a number of ideas (specifically, Fermi problems and tutoring in the style of the *Princeton Learning Guide*). The idea is to start with simple estimation problems and then build up to Fermi problems (in early chapters Fermi problems are hard to compose because few concepts have been introduced). Because students initially find these questions hard, the section provides many hints, which take the form of guiding questions. A key then provides answers to these "hints." These Developing a Feel questions are now included in Mastering Physics.
3. *Worked and Guided Problems*. This section contains worked examples whose primary goal is to teach problem solving. The Worked Problems are fully solved; the Guided Problems have a list of guiding questions and suggestions to help the student think about how to solve the problem. Typically, each Worked Problem is followed by a related Guided Problem. Both are available in Mastering Physics.

Instructor supplements

Downloadable ***Instructor Resources*** includes an Image Library, **Lecture Outlines** with embedded **Clicker Questions in PowerPoint®**, and the ***Instructor's Solutions Manual***.

The ***Instructor's Solutions Manual*** is a comprehensive solutions manual containing complete answers and solutions to Questions and Problems found at the end of each chapter, as well as all Developing a Feel questions and Guided Problems found in Mastering Physics. The solutions to the Guided Problems use the book's four-step problem-solving strategy (Getting Started, Devise Plan, Execute Plan, Evaluate Result).

Mastering Physics® is the leading online homework, tutorial, and assessment product designed to improve results by helping students quickly master concepts. Students benefit from self-paced tutorials that feature specific wrong-answer feedback, hints, and a wide variety of educationally effective content to keep them engaged and on track. Robust diagnostics and unrivalled gradebook reporting allow instructors to pinpoint the weaknesses and misconceptions of a student or class to provide timely intervention.

Mastering Physics enables instructors to:

- Easily assign **tutorials** that provide individualized coaching.
- Mastering's hallmark **Hints** and **Feedback** offer scaffolded instruction similar to what students would experience in an office hour.
- **Hints** (declarative and Socratic) can provide problem-solving strategies or break the main problem into simpler exercises.
- **Feedback** lets the student know precisely what misconception or misunderstanding is evident from their answer and offers ideas to consider when attempting the problem again.

Learning Catalytics™ is a "bring your own device" student engagement, assessment, and classroom intelligence system available within Mastering Physics. With Learning Catalytics you can:

- Assess students in real time, using open-ended tasks to probe student understanding.
- Understand immediately where students are and adjust your lecture accordingly.
- Improve your students' critical-thinking skills.
- Access rich analytics to understand student performance.
- Add your own questions to make Learning Catalytics fit your course exactly.
- Manage student interactions with intelligent grouping and timing.

The **Test Bank** contains more than 2000 high-quality problems, with a range of multiple-choice, true-false, short-answer, and conceptual questions correlated to *Principles & Practice of Physics* chapters. Test files are provided in both TestGen® and Microsoft® Word for Mac and PC.

Instructor supplements are available in the Instructor Resource area of Mastering Physics (www.masteringphysics.com).

Student supplements

Mastering Physics (www.masteringphysics.com) is designed to provide students with customized coaching and individualized feedback to help improve problem-solving skills. Students complete homework efficiently and effectively with tutorials that provide targeted help. By combining trusted author content with digital tools developed to engage students and emulate the office-hour experience, Mastering personalizes learning and improves results for each student. Built for, and directly tied to the text, Mastering Physics gives students a platform to practice, learn, and apply knowledge outside of the classroom.

Acknowledgments

This book would not exist without the contributions from many people. It was Tim Bozik, currently the President of Global Product at Pearson, who first approached me about writing a physics textbook. If it wasn't for his persuasion and his belief in me, I don't think I would have ever undertaken the writing of a textbook. Tim's suggestion to develop the art electronically also had a major impact on my approach to the development of the visual part of this book.

Albert Altman pointed out Ernst Mach's approach to developing mechanics starting with the law of conservation of momentum. Al encouraged me throughout the years as I struggled to reorganize the material around the conservation principles.

I am thankful to those who assisted on the first edition: Irene Nunes, who served as Development Editor through several iterations of the manuscript. Irene forced me to continuously rethink what I had written and her insights in physics kept surprising me. Her incessant questioning taught me that one doesn't need to be a science major to obtain a deep understanding of how the world around us works and that it is possible to explain physics in a way that makes sense for non-physics majors. Catherine Crouch helped write the final chapters of electricity and magnetism and the chapters on circuits and optics, permitting me to focus on the overall approach and the art program. Peter Dourmashkin helped me write the chapters on special relativity and thermodynamics. I appreciate Daryl Pedigo's hard work authoring, editing content, and coordinating the contributions to all of the practice material in this book. Also, Peter Dourmashkin and Wolfgang Rueckner helped me with some of the experiments that form the basis of the illustrations in a number of the chapters. Lastly, I would also like to thank my late uncle, Erich Lessing, for letting me use some of his beautiful pictures as chapter openers.

Many people provided feedback during the development of the first edition manuscript. I am particularly indebted to the late Ronald Newburgh and to Edward Ginsberg, who meticulously checked many of the chapters. I am also grateful to Edwin Taylor for his critical feedback on the special relativity chapter and to my colleague Gary Feldman for his suggestions for improving that chapter. Lisa Morris provided material for many of the Self-quizzes and my graduate students James Carey, Mark Winkler, and Ben Franta helped with data analysis and the appendices. The following people provided the material for the first edition Practice book: Wayne Anderson, Bill Ashmanskas, Linda Barton, Ronald Bieniek, Michael Boss, Anthony Buffa, Catherine Crouch, Peter Dourmashkin, Paul Draper, Andrew Duffy, Edward Ginsberg, William Hogan, Gerd Kortemeyer, Rafael Lopez-Mobilia, Chris-topher Porter, David Rosengrant, Gay Stewart, Christopher Watts, Lawrence Weinstein, Fred Wietfeldt, and Michael Wofsey.

I would also like to thank the editorial and production staff at Pearson. Margot Otway helped realize my vision for the art program. I would like to thank Darien Estes for helping conceive the second edition of this book, Jeanne Zalesky for her input, Deb Harden and Heidi Allgair for managing the process of getting things done, Karen Karlin who was my development editor for this edition, Jenny Moryan for coordinating the shooting of the videos, and Paul Corey for his continued support and belief in me. I am also indebted to David Bannon (Oregon State University), Jason Harlow (University of Toronto), and Michael Faux for their thorough accuracy checking. Frank Chmly helped prepare the reading questions for Mastering and Ken DeNisco helped with slides and Ready To Go Teaching Modules and with the accuracy checking of digital items. Finally, I would like to thank my colleague Greg Kestin for contributing his videos to the second edition.

I am also grateful to the participants of the NSF Faculty Development Conference "Teaching Physics Conservation Laws First" held in Cambridge, MA, in 1997. This conference helped validate and cement the approach in this book.

I am continuously indebted to the hundreds of students in Physics 1, Physics 11, and Applied Physics 50 who used early versions of this text in their course and provided the feedback that ended up turning my manuscript into a text that works not just for instructors but, more importantly, for students.

Reviewers of *Principles & Practice of Physics*

Over the years many people reviewed and class-tested the manuscript. The author and publisher are grateful for all of the feedback the reviewers provided, and we apologize if there are any names on this list that have been inadvertently omitted.

Detailed Contents

About the Author 4
To the Student 5
To the Instructor 6
Acknowledgments 10

CHAPTER 1 **Foundations 19**

1.1 The scientific method 20
1.2 Symmetry 22
1.3 Matter and the universe 24
1.4 Time and change 26
1.5 Representations 27
1.6 Physical quantities and units 32
1.7 Significant digits 35
1.8 Solving problems 38
1.9 Developing a feel 42

CHAPTER 2 **Motion in One Dimension 53**

2.1 From reality to model 54
2.2 Position and displacement 55
2.3 Representing motion 57
2.4 Average speed and average velocity 59
2.5 Scalars and vectors 64
2.6 Position and displacement vectors 66
2.7 Velocity as a vector 70
2.8 Motion at constant velocity 71
2.9 Instantaneous velocity 73

CHAPTER 3 **Acceleration 86**

3.1 Changes in velocity 87
3.2 Acceleration due to gravity 88
3.3 Projectile motion 90
3.4 Motion diagrams 92
3.5 Motion with constant acceleration 96
3.6 Free-fall equations 99
3.7 Inclined planes 102
3.8 Instantaneous acceleration 103

CHAPTER 4 **Momentum 116**

4.1 Friction 117
4.2 Inertia 117
4.3 What determines inertia? 121
4.4 Systems 122
4.5 Inertial standard 127
4.6 Momentum 128
4.7 Isolated systems 130
4.8 Conservation of momentum 135

CHAPTER 5 **Energy 149**

5.1 Classification of collisions 150
5.2 Kinetic energy 151
5.3 Internal energy 153
5.4 Closed systems 156
5.5 Elastic collisions 160
5.6 Inelastic collisions 163
5.7 Conservation of energy 164
5.8 Explosive separations 166

CHAPTER 6 **Principle of Relativity 176**

6.1 Relativity of motion 177
6.2 Inertial reference frames 179
6.3 Principle of relativity 181
6.4 Zero-momentum reference frame 186
6.5 Galilean relativity 189
6.6 Center of mass 193
6.7 Convertible kinetic energy 198
6.8 Conservation laws and relativity 201

CHAPTER 7 **Interactions 211**

7.1 The effects of interactions 212
7.2 Potential energy 215
7.3 Energy dissipation 216
7.4 Source energy 219
7.5 Interaction range 222
7.6 Fundamental interactions 224
7.7 Interactions and accelerations 228
7.8 Nondissipative interactions 229
7.9 Potential energy near Earth's surface 232
7.10 Dissipative interactions 235

CHAPTER 8 **Force 246**

8.1 Momentum and force 247
8.2 The reciprocity of forces 248
8.3 Identifying forces 250
8.4 Translational equilibrium 251
8.5 Free-body diagrams 252
8.6 Springs and tension 255
8.7 Equation of motion 259
8.8 Force of gravity 262
8.9 Hooke's law 263
8.10 Impulse 265
8.11 Systems of two interacting objects 267
8.12 Systems of many interacting objects 269

CHAPTER 9 **Work 282**

9.1 Force displacement 283
9.2 Positive and negative work 284
9.3 Energy diagrams 286
9.4 Choice of system 289
9.5 Work done on a single particle 293
9.6 Work done on a many-particle system 296
9.7 Variable and distributed forces 300
9.8 Power 303

CHAPTER 10 **Motion in a Plane 314**

10.1 *Straight* is a relative term 315
10.2 Vectors in a plane 316
10.3 Decomposition of forces 319
10.4 Friction 322
10.5 Work and friction 323
10.6 Vector algebra 326
10.7 Projectile motion in two dimensions 328
10.8 Collisions and momentum in two dimensions 330
10.9 Work as the product of two vectors 331
10.10 Coefficients of friction 336

CHAPTER 11 **Motion in a Circle 351**

11.1 Circular motion at constant speed 352
11.2 Forces and circular motion 356
11.3 Rotational inertia 358
11.4 Rotational kinematics 362
11.5 Angular momentum 367
11.6 Rotational inertia of extended objects 372

CHAPTER 12 **Torque 388**

12.1 Torque and angular momentum 389
12.2 Free rotation 392
12.3 Extended free-body diagrams 393
12.4 The vectorial nature of rotation 395
12.5 Conservation of angular momentum 400
12.6 Rolling motion 404
12.7 Torque and energy 409
12.8 The vector product 411

CHAPTER 13 **Gravity 425**

13.1 Universal gravity 426
13.2 Gravity and angular momentum 431
13.3 Weight 434
13.4 Principle of equivalence 438
13.5 Gravitational constant 442
13.6 Gravitational potential energy 443
13.7 Celestial mechanics 446
13.8 Gravitational force exerted by a sphere 451

CHAPTER 14 **Special Relativity 461**

14.1 Time measurements 462
14.2 *Simultaneous* is a relative term 465
14.3 Space-time 469
14.4 Matter and energy 474

14.5 Time dilation 479
14.6 Length contraction 484
14.7 Conservation of momentum 488
14.8 Conservation of energy 492

CHAPTER 15 **Periodic Motion 504**

15.1 Periodic motion and energy 505
15.2 Simple harmonic motion 507
15.3 Fourier's theorem 509
15.4 Restoring forces in simple harmonic motion 511
15.5 Energy of a simple harmonic oscillator 516
15.6 Simple harmonic motion and springs 520
15.7 Restoring torques 524
15.8 Damped oscillations 527

CHAPTER 16 **Waves in One Dimension 539**

16.1 Representing waves graphically 540
16.2 Wave propagation 544
16.3 Superposition of waves 548
16.4 Boundary effects 550
16.5 Wave functions 556
16.6 Standing waves 562
16.7 Wave speed 564
16.8 Energy transport in waves 567
16.9 The wave equation 569

CHAPTER 17 **Waves in Two and Three Dimensions 580**

17.1 Wavefronts 581
17.2 Sound 584
17.3 Interference 587
17.4 Diffraction 592
17.5 Intensity 596
17.6 Beats 599
17.7 Doppler effect 602
17.8 Shock waves 607

CHAPTER 18 **Fluids 616**

18.1 Forces in a fluid 617
18.2 Buoyancy 622
18.3 Fluid flow 624
18.4 Surface effects 628
18.5 Pressure and gravity 635
18.6 Working with pressure 640
18.7 Bernoulli's equation 644
18.8 Viscosity and surface tension 647

CHAPTER 19 **Entropy 664**

19.1 States 665
19.2 Equipartition of energy 669
19.3 Equipartition of space 670
19.4 Evolution toward the most probable macrostate 673
19.5 Dependence of entropy on volume 678
19.6 Dependence of entropy on energy 683
19.7 Properties of a monatomic ideal gas 687
19.8 Entropy of a monatomic ideal gas 690

CHAPTER 20 **Energy Transferred Thermally 701**

20.1 Thermal interactions 702
20.2 Temperature measurement 706
20.3 Heat capacity 709
20.4 *PV* diagrams and processes 713
20.5 Change in energy and work 719
20.6 Isochoric and isentropic ideal gas processes 721
20.7 Isobaric and isothermal ideal gas processes 723

20.8 Entropy change in ideal gas processes 727
20.9 Entropy change in nonideal gas processes 731

CHAPTER 21 **Degradation of Energy 742**
21.1 Converting energy 743
21.2 Quality of energy 746
21.3 Heat engines and heat pumps 750
21.4 Thermodynamic cycles 756
21.5 Entropy constraints on energy transfers 761
21.6 Heat engine performance 764
21.7 Carnot cycle 768
21.8 Brayton cycle 770

CHAPTER 22 **Electric Interactions 783**
22.1 Static electricity 784
22.2 Electrical charge 785
22.3 Mobility of charge carriers 788
22.4 Charge polarization 793
22.5 Coulomb's law 796
22.6 Forces exerted by distributions of charge carriers 800

CHAPTER 23 **The Electric Field 813**
23.1 The field model 814
23.2 Electric field diagrams 816
23.3 Superposition of electric fields 817
23.4 Electric fields and forces 820
23.5 Electric field of a charged particle 824
23.6 Dipole field 825
23.7 Electric fields of continuous charge distributions 827
23.8 Dipoles in electric fields 832

CHAPTER 24 **Gauss's Law 845**
24.1 Electric field lines 846
24.2 Field line density 848
24.3 Closed surfaces 849
24.4 Symmetry and Gaussian surfaces 851
24.5 Charged conducting objects 854
24.6 Electric flux 858
24.7 Deriving Gauss's law 860
24.8 Applying Gauss's law 862

CHAPTER 25 **Work and Energy in Electrostatics 878**
25.1 Electric potential energy 879
25.2 Electrostatic work 880
25.3 Equipotentials 882
25.4 Calculating work and energy in electrostatics 886
25.5 Potential difference 889
25.6 Electrostatic potentials of continuous charge distributions 895
25.7 Obtaining the electric field from the potential 897

CHAPTER 26 **Charge Separation and Storage 908**

26.1 Charge separation 909
26.2 Capacitors 911
26.3 Dielectrics 915
26.4 Voltaic cells and batteries 917
26.5 Capacitance 921
26.6 Electric field energy and emf 925
26.7 Dielectric constant 928
26.8 Gauss's law in dielectrics 931

CHAPTER 27 **Magnetic Interactions 941**

27.1 Magnetism 942
27.2 Magnetic fields 944
27.3 Charge flow and magnetism 946
27.4 Magnetism and relativity 949
27.5 Current and magnetism 954
27.6 Magnetic flux 956
27.7 Moving particles in electric and magnetic fields 958
27.8 Magnetism and electricity unified 963

CHAPTER 28 **Magnetic Fields of Charged Particles in Motion 976**

28.1 Source of the magnetic field 977
28.2 Current loops and spin magnetism 978
28.3 Magnetic dipole moment and torque 980
28.4 Ampèrian paths 983
28.5 Ampère's law 987
28.6 Solenoids and toroids 990
28.7 Magnetic fields due to currents 993
28.8 Magnetic field of a moving charged particle 996

CHAPTER 29 **Changing Magnetic Fields 1011**

29.1 Moving conductors in magnetic fields 1012
29.2 Faraday's law 1014
29.3 Electric fields accompany changing magnetic fields 1015
29.4 Lenz's law 1016
29.5 Induced emf 1021
29.6 Electric field accompanying a changing magnetic field 1025
29.7 Inductance 1027
29.8 Magnetic energy 1029

CHAPTER 30 **Changing Electric Fields 1042**

30.1 Magnetic fields accompany changing electric fields 1043
30.2 Fields of moving charged particles 1046
30.3 Oscillating dipoles and antennas 1049
30.4 Displacement current 1055
30.5 Maxwell's equations 1059
30.6 Electromagnetic waves 1062
30.7 Electromagnetic energy 1067

CHAPTER 31 **Electric Circuits 1079**

31.1 The basic circuit 1080
31.2 Current and resistance 1082
31.3 Junctions and multiple loops 1084
31.4 Electric fields in conductors 1088
31.5 Resistance and Ohm's law 1092
31.6 Single-loop circuits 1096
31.7 Multiloop circuits 1101
31.8 Power in electric circuits 1106

CHAPTER 32 **Electronics 1121**

32.1 Alternating currents 1122
32.2 AC circuits 1124
32.3 Semiconductors 1128
32.4 Diodes, transistors, and logic gates 1130
32.5 Reactance 1136
32.6 *RC* and *RLC* series circuits 1141
32.7 Resonance 1148
32.8 Power in AC circuits 1150

CHAPTER 33 **Ray Optics 1164**

33.1 Rays 1165
33.2 Absorption, transmission, and reflection 1166
33.3 Refraction and dispersion 1169
33.4 Forming images 1173
33.5 Snel's law 1180
33.6 Thin lenses and optical instruments 1183
33.7 Spherical mirrors 1190
33.8 Lensmaker's formula 1193

CHAPTER 34 **Wave and Particle Optics 1207**

34.1 Diffraction of light 1208
34.2 Diffraction gratings 1210
34.3 X-ray diffraction 1213
34.4 Matter waves 1217
34.5 Photons 1218
34.6 Multiple-slit interference 1222
34.7 Thin-film interference 1227
34.8 Diffraction at a single-slit barrier 1229
34.9 Circular apertures and limits of resolution 1231
34.10 Photon energy and momentum 1234

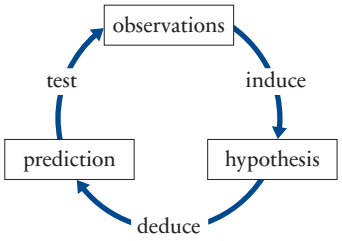
CONCEPTS

QUANTITATIVE TOOLS

Chances are you are taking this course in physics because someone told you to take it, and it may not be clear to you *why* you should be taking it. One good reason for taking a physics course is that, first and foremost, physics provides a fundamental understanding of the world. Furthermore, whether you are majoring in psychology, engineering, biology, physics, or something else, this course offers you an opportunity to sharpen your reasoning skills. Knowing physics means becoming a better problem solver (and I mean *real* problems, not textbook problems that have already been solved), and becoming a better problem solver is empowering: It allows you to step into unknown territory with more confidence. Before we embark on this exciting journey, let's map out the territory we are going to explore so that you know where we are going.



1.1 The scientific method

Physics, from the Greek word for "nature," is commonly defined as the study of matter and motion. Physics is about discovering the wonderfully simple unifying patterns that underlie absolutely everything that happens around us, from the scale of subatomic particles, to the microscopic world of DNA molecules and cells, to the cosmic scale of stars, galaxies, and planets. Physics deals with atoms and molecules; gases, solids, and liquids; everyday objects and black holes. Physics explores motion, light, and sound; the creation and annihilation of matter; evaporation and melting; electricity and magnetism. Physics is all around you: in the Sun that provides your daylight, in the structure of your bones, in your computer, in the motion of a ball you throw. In a sense, then, physics is the study of all there is in the universe. Indeed, biology, engineering, chemistry, astronomy, geology, and so many other disciplines you might name all use the principles of physics.

The many remarkable scientific accomplishments of ancient civilizations that survive to this day testify to the fact that curiosity about the world is part of human nature. Physics evolved from *natural philosophy*—a body of knowledge accumulated in ancient times in an attempt to explain the behavior of the universe through philosophical speculation—and became a distinct discipline during the scientific revolution that began in the 16th century. One of the main changes that occurred in that century was the development of the **scientific method,** an iterative process for going from observations to validated theories.

In its simplest form, the scientific method works as follows (**Figure 1.1**): A researcher makes a number of observations concerning either something happening in the natural world (a volcano erupting, for instance) or something happening during a laboratory experiment (a dropped brick and a dropped Styrofoam peanut travel to the floor at different speeds). These observations then lead the researcher to formulate a **hypothesis,** which is a tentative explanation of the observed phenomenon. The hypothesis is used to predict the outcome of some related natural occurrence (how a similarly shaped mountain near the erupting volcano will behave) or related laboratory experiment (what happens when a book and a sheet of paper are dropped at the same time). If the predictions prove inaccurate, the hypothesis must be modified. If the predictions prove accurate in test after test, the hypothesis is elevated to the status of either a **law** or a **theory.**

Figure 1.1 The scientific method is an iterative process in which a hypothesis, which is inferred from observations, is used to make a prediction, which is then tested by making new observations.

A law tells us *what* happens under certain circumstances. Laws are usually expressed in the form of relationships between observable quantities. A theory tells us *why* something happens and explains phenomena in terms of more basic processes and relationships. A scientific theory is not a mere conjecture or speculation. It is a thoroughly tested explanation of a natural phenomenon, one that is capable of making predictions that can be verified by experiment. The constant testing and retesting are what make the scientific method such a powerful tool for investigating the universe: The results obtained must be repeatable and verifiable by others.

CONCEPTS

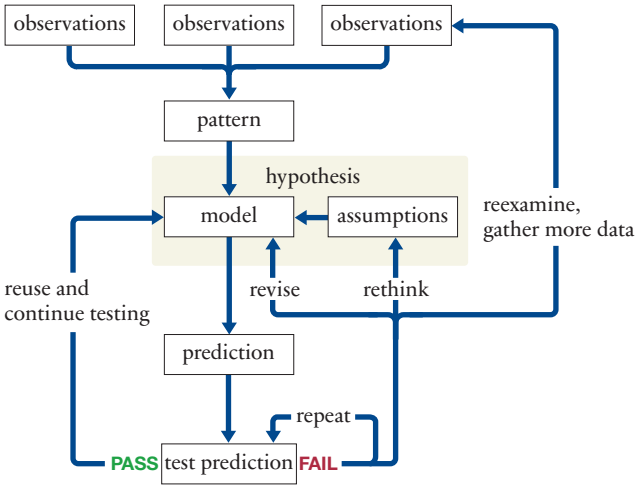
EXERCISE 1.1 Hypothesis or not?

Which of the following statements are hypotheses? (*a*) Heavier objects fall to Earth faster than lighter ones. (*b*) The planet Mars is inhabited by invisible beings that are able to elude any type of observation. (*c*) Distant planets harbor forms of life. (*d*) Handling toads causes warts.

SOLUTION (*a*), (*c*), and (*d*). A hypothesis must be experimentally verifiable. (*a*) I can verify this statement by dropping a heavy object and a lighter one at the same instant and observing which one hits the ground first. (*b*) This statement asserts that the beings on Mars cannot be observed, which precludes any experimental verification and means this statement is not a valid hypothesis. (*c*) Although we humans currently have no means of exploring or closely observing distant planets, the statement is in principle testable. (*d*) Even though we know this statement is false, it *is* verifiable and therefore is a hypothesis.

Because of the constant reevaluation demanded by the scientific method, science is not a stale collection of facts but rather a living and changing body of knowledge. More

important, any theory or law *always* remains tentative, and the testing never ends. In other words, it is not possible to prove any scientific theory or law to be absolutely true (or even absolutely false). Thus the material you will learn in this book does not represent some "ultimate truth"—it is true only to the extent that it has not been proved wrong.



A case in point is *classical mechanics,* a theory developed in the 17th century to describe the motion of everyday objects (and the subject of most of this book). Although this theory produces accurate results for most everyday phenomena, from balls thrown in the air to satellites orbiting Earth, observations made during the last hundred years have revealed that under certain circumstances, significant deviations from this theory occur. It is now clear that classical mechanics is applicable for only a limited (albeit important) range of phenomena, and new branches of physics—*quantum mechanics* and the theory of *special relativity* among them—are needed to describe the phenomena that fall outside the range of classical mechanics.

The formulation of a hypothesis almost always involves developing a **model,** which is a simplified conceptual representation of some phenomenon. You don't have to be trained as a scientist to develop models. Everyone develops mental models of how people behave, how events unfold, and how things work. Without such models, we would not be able to understand our experiences, decide what actions to take, or handle unexpected experiences. Examples of models we use in everyday life are that door handles and door hinges are on opposite sides of doors and that the + button on a TV remote increases the volume or the channel number. In everyday life, we base our models on whatever knowledge we have, real or imagined, complete or incomplete. In science we must build models based on careful observation and determine ways to fill in any missing information.

Let's look at the iterative process of developing models and hypotheses in physics, with an eye toward determining what skills are needed and what pitfalls are to be avoided (**Figure 1.2**). Developing a scientific hypothesis often begins with recognizing patterns in a series of observations. Sometimes these observations are direct, but sometimes we must settle for indirect observations. (We cannot directly observe the nucleus of an atom, for instance, but a physicist can describe the structure of the nucleus and its behavior with great certainty and accuracy.) As Figure 1.2 indicates, the patterns that emerge from our observations must often be combined with simplifying assumptions to build a model. The combination of model and assumptions is what constitutes a hypothesis.

It may seem like a shaky proposition to build a hypothesis on assumptions that are accepted without proof, but making these assumptions—*consciously*—is a crucial step in making sense of the universe. All that is required is that, when formulating a hypothesis, we must be aware

Figure 1.2 Iterative process for developing a scientific hypothesis.

of these assumptions and be ready to revise or drop them if the predictions of our hypothesis are not validated. We should, in particular, watch out for what are called *hidden assumptions*—assumptions we make without being aware of them. As an example, try answering the following question. (Turn to the final section of this book, "Solutions to checkpoints," for the answer.)

1.1 I have two coins in my pocket, together worth 30 cents. If one of them is not a nickel, what coins are they?

Advertising agencies and magicians are masters at making us fall into the trap of hidden assumptions. Imagine a radio commercial for a new drug in which someone says, "Baroxan lowered my blood pressure tremendously." If you think that sounds good, you have made a number of assumptions without being aware of them—in other words, hidden assumptions. Who says, for instance, that lowering blood pressure "tremendously" is a good thing (dead people have tremendously low blood pressure) or that the speaker's blood pressure was too high to begin with?

Magic, too, involves hidden assumptions. The trick in some magic acts is to make you assume that something happens, often by planting a false assumption in your mind. A magician might ask, "How did I move the ball from here to there?" while in reality he is using two balls. I won't knowingly put false assumptions into *your* mind in this book, but on occasion you and I (or you and your instructor) may unknowingly make different assumptions during a given discussion, a situation that unavoidably leads to confusion and misunderstanding. Therefore it is important that we carefully analyze our thinking and watch for the assumptions that we build into our models.

If the prediction of a hypothesis fails to agree with observations made to test the hypothesis, there are several ways to address the discrepancy. One way is to rerun the

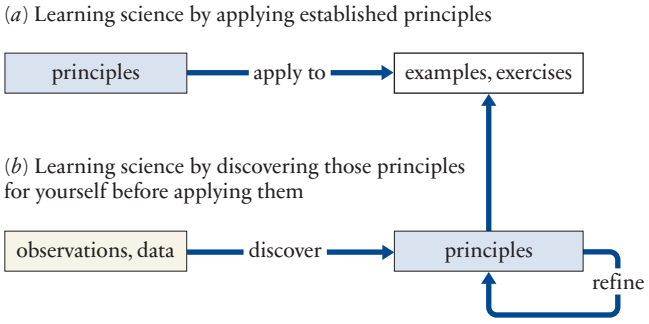
CONCEPTS

test to see if it is reproducible. If the test keeps producing the same result, it becomes necessary to revise the hypothesis, rethink the assumptions that went into it, or reexamine the original observations that led to the hypothesis.

EXERCISE 1.2 Stopped clock

A battery-operated wall clock no longer keeps time—neither hand moves. Develop a hypothesis explaining why it fails to work, and then make a prediction that permits you to test your hypothesis. Describe two possible outcomes of the test and what you conclude from the outcomes. (*Think* before you peek at the answer below.)

SOLUTION There are many reasons the clock might not run. Here is one example. Hypothesis: The batteries are dead. Prediction: If I replace the batteries with new ones, the clock should work. Possible outcomes: (1) The clock works once the new batteries are installed, which means the hypothesis is supported; (2) the clock doesn't work after the new batteries are installed, which means the hypothesis is not supported and must be either modified or discarded.



1.2 In Exercise 1.2, each of the conclusions drawn from the two possible outcomes contains a hidden assumption. What are the hidden assumptions?

The development of a scientific hypothesis is often more complicated than suggested by Figures 1.1 and 1.2. Hypotheses do not always start with observations; some are developed from incomplete information, vague ideas, assumptions, or even complete guesses. The refining process also has its limits. Each refinement adds complexity, and at some point the complexity outweighs the benefit of the increased accuracy. Because we like to think that the universe has an underlying simplicity, it might be better to scrap the hypothesis and start anew.

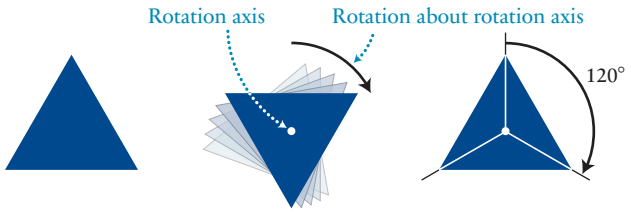
Figure 1.2 gives an idea of the skills that are useful in doing science: interpreting observations, recognizing patterns, making and recognizing assumptions, thinking logically, developing models, and using models to make predictions. It should not come as any surprise to you that many of these skills are useful in just about any context. Learning physics allows you to sharpen these skills in a very rigorous way. So, whether you become a financial analyst, a doctor, an engineer, or a research scientist (to name just a few possibilities), there is a good reason to take physics.

Figure 1.1 also shows that doing science—and physics in particular—involves two types of reasoning: *inductive*, which is arguing from the specific to the general, and *deductive*, arguing from the general to the specific. The most creative part of doing physics involves inductive reasoning, and this fact sheds light on how you might want to learn physics. One way, which is neither very useful nor very satisfying, is for me to simply tell you all the general principles physicists presently agree on and then for you to apply those principles in examples and exercises (**Figure 1.3*a***).This approach involves deductive reasoning only and robs you of the opportunity to learn the skill that is the most likely to benefit your career: discovering underlying patterns. Another way is for me to present you with data and observations and make you part of the discovery and refinement of the physics principles (Figure 1.3*b*). This approach is more time-consuming, and sometimes you may wonder why I'm not just *telling* you the final outcome. The reason is that discovery and refinement are at the heart of doing physics!

Figure 1.3

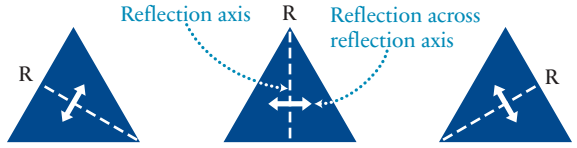
1.3 After reading this section, reflect on your goals for this course. Write down what you would like to accomplish and why you would like to accomplish this. Once you have done that, turn to the final section of this book, "Solutions to checkpoints," and compare what you have written with what I wrote.

1.2 Symmetry



One of the basic requirements of any law of the universe involves what physicists call *symmetry,* a concept often associated with order, beauty, and harmony. We can define **symmetry** as follows: An object exhibits symmetry when certain operations can be performed on it without changing its appearance. Consider the equilateral triangle in **Figure 1.4*a***. If you close your eyes and someone rotates the triangle by 120° while you have your eyes closed, the triangle appears the same when you open your eyes, and you can't tell that it has been rotated. The triangle is said to have *rotational symmetry,* one of several types of geometrical symmetry.

Another common type of geometrical symmetry, *reflection symmetry,* occurs when one half of an object is the mirror image of the other half. The equilateral triangle in Figure 1.4 possesses reflection symmetry about the three axes shown in Figure 1.4*b*. If you imagine folding the triangle in half over each axis, you can see that the two halves are identical. Reflection symmetry occurs all around us: in the arrangement of atoms in crystals (**Figure 1.5*a*** and *b*) and in the anatomy of most life forms (Figure 1.5*c*), to name just two examples.



CONCEPTS

Figure 1.4

(*a*) Rotational symmetry: Rotating an equilateral triangle by 120° doesn't change how it looks

(*b*) Reflection symmetry: Across each reflection axis (labeled R), two sides of the triangle are mirror images of each other

The ideas of symmetry—that something appears unchanged under certain operations—apply not only to the shape of objects but also to the more abstract realm of physics. If there are things we can do to an experiment that leave the result of the experiment unchanged, then the phenomenon tested by the experiment is said to possess certain symmetries. Suppose we build an apparatus, carry out a certain measurement in a certain location, then move the apparatus to another location, repeat the measurement, and get the same result in both locations.* By moving the apparatus to a new location (*translating* it) and obtaining the same result, we have shown that the observed phenomenon has *translational symmetry*. Any physical law that describes this phenomenon must therefore mathematically exhibit translational symmetry; that is, the mathematical expression of this law must be independent of the location.

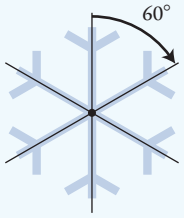
*In moving our apparatus, we must take care to move any relevant external influences along with it. For example, if Earth's gravity is of importance, then moving the apparatus to a location in space far from Earth does not yield the same result.

Likewise, we expect any measurements we make with our apparatus to be the same at a later time as at an earlier time; that is, translation in time has no effect on the measurements. The laws describing the phenomenon we are studying must therefore mathematically exhibit symmetry under translation in time; in other words, the mathematical expression of these laws must be independent of time.

EXERCISE 1.3 Change is no change

Figure 1.6 shows a snowflake. Does the snowflake have rotational symmetry? If yes, describe the ways in which the flake can be rotated without changing its appearance. Does it have reflection symmetry? If yes, describe the ways in which the flake can be split in two so that one half is the mirror image of the other.

Figure 1.6 Exercise 1.3.



SOLUTION I can rotate the snowflake by 60° or a multiple of 60° (120°, 180°, 240°, 300°, and 360°) in the plane of the photograph without changing its appearance (**Figure 1.7*a***). It therefore has rotational symmetry.

I can also fold the flake in half along any of the three blue axes and along any of the three red axes in Figure 1.7*b*. The flake therefore has reflection symmetry about all six of these axes.

Figure 1.7

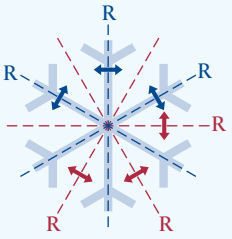

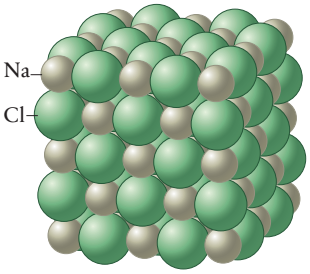

Figure 1.5 The symmetrical arrangement of atoms in a salt crystal gives these crystals their cubic shape.

(*a*) Micrograph of salt crystals

(*b*) Symmetrical arrangement of atoms in a salt crystal

(*c*) Da Vinci's Vitruvian Man shows the reflection symmetry of the human body

CONCEPTS

A number of such symmetries have been identified, and the basic laws that govern the inner workings of the physical world must reflect these symmetries. Some of these symmetries are familiar to you, such as translational symmetry in space or time. Others, like electrical charge or parity symmetry, are unfamiliar and surprising and go beyond the scope of this course. Whereas symmetry has always implicitly been applied to the description of the universe, it plays an increasingly important role in physics: In a sense the quest of physics in the 21st century is the search for (and test of) symmetries because these symmetries are the most fundamental principles that all physical laws must obey.

1.4 You always store your pencils in a cylindrical case. One day while traveling in the tropics, you discover that the cap, which you have placed back on the case day in, day out for years, doesn't fit over the case. What do you conclude?

1.3 Matter and the universe

The goal of physics is to describe all that happens in the universe. Simply put, the **universe** is the totality of matter and energy combined with the space and time in which all events happen—everything that is directly or indirectly observable. To describe the universe, we use *concepts*, which are ideas or general notions used to analyze natural phenomena.* To provide a quantitative description, these concepts must be expressed quantitatively, which requires defining a procedure for measuring them. Examples are the length or mass of an object, temperature, and time intervals. Such **physical quantities** are the cornerstones of physics. It is the accurate measurement of physical quantities that has led to the great discoveries of physics. Although many of the fundamental concepts we use in this book are familiar ones, quite a few are difficult to define in words, and we must often resort to defining these concepts in terms of the procedures used to measure them.

The fundamental physical quantity by which we map out the universe is **length**—a distance or an extent in space. The length of a straight or curved line is measured by comparing the length of the line with some standard length. In 1791, the French Academy of Sciences defined the standard unit for length, called the **meter** and abbreviated m, as one ten-millionth of the distance from the equator to the North Pole. For practical reasons, the standard was redefined in 1889 as the distance between two fine lines engraved on a bar of platinum-iridium alloy kept at the International Bureau of Weights and Measures near Paris. With the advent of lasers, however, it became possible to measure the speed of light with extraordinary accuracy, and so the meter was redefined in 1983 as the distance traveled by light in vacuum in a time interval of 1/299,792,458 of a second. This number is chosen so as to make the speed of light exactly 299,792,458 meters per second and yield a standard length for the meter that is very close to the length of the original platinum-iridium standard. This laser-based standard may never need to be revised.

1.5 Based on the early definition of the meter, one ten-millionth of the distance from the equator to the North Pole, what is Earth's radius?

Now that we have defined a standard for length, let us use this standard to discuss the structure and size scales of the universe. Because of the extraordinary range of size scales in the universe, we shall round off any values to the nearest power of ten. Such a value is called an **order of magnitude.** For example, any number between 0.3 and 3 has an order of magnitude of 1 because it is within a factor of 3 of 1; any number greater than 3 and equal to or less than 30 has an order of magnitude of 10. You determine the order of magnitude of any quantity by writing it in scientific notation and rounding the coefficient in front of the power of ten to 1 if it is equal to or less than 3 or to 10 if it is greater than 3.† For example, 3 minutes is 180 s, which can be written as 1.8×10^2 s. The coefficient, 1.8, rounds to 1, and so the order of magnitude is 1×10^2 s $= 10^2$ s. The quantity 680, to take another example, can be written as 6.8×10^2; the coefficient 6.8 rounds to 10, and so the order of magnitude is $10 \times 10^2 = 10^3$. And Earth's circumference is 40,000,000 m, which can be written as 4×10^7 m; the order of magnitude of this number is 10^8 m. You may think that using order-of-magnitude approximations is not very scientific because of the lack of accuracy, but the ability to work effectively with orders of magnitude is a key skill not just in science but also in any other quantitative field of endeavor.

All ordinary matter in the universe is made up of basic building blocks called **atoms** (Figure 1.8). Nearly all the matter in an atom is contained in a dense central nucleus, which consists of **protons** and **neutrons,** two types of subatomic particles. A tenuous *cloud* of **electrons,** a third type of subatomic particle, surrounds this nucleus. To an approximation, atoms are spherical and have a diameter of about 10^{-10} m. Spherical atomic nuclei have a diameter of about 10^{-15} m, making atoms mostly empty space. Atoms attract one another when they are a small distance apart but resist being squeezed into one another. The arrangement of atoms in a material helps determine the properties of the material.

CONCEPTS

*When an important concept is introduced in this book, the main word pertaining to the concept is printed in **boldface type.** All important concepts introduced in a chapter are listed at the back of this book, in the Glossary.

†The reason we use 3 in order-of-magnitude rounding, and not 5 as in ordinary rounding, is that orders of magnitude are logarithmic, and on this logarithmic scale log 3 = 0.48 lies nearly halfway between log 1 = 0 and log 10 = 1.

Figure 1.8 Scanning tunneling microscope image showing the individual atoms that make up a silicon surface. The size of each atom is about 1/50,000 the width of a human hair.

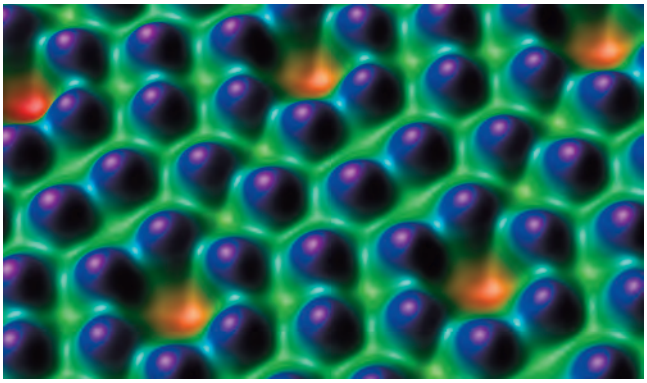

Figure 1.9 shows the relative size of some representative objects in the universe. The figure reveals a lot about the organization of matter in the universe and serves as a visual model of the structure of the universe. Roughly speaking, there is clustering of matter from smaller to larger at four length scales. At the subatomic scale, most of the matter in an atom is compressed into the tiny atomic nucleus, a cluster of subatomic particles. Atoms, in turn, cluster to form the objects and materials that surround us, from viruses to plants, animals, and other everyday objects. The next level is the clustering of matter in stars, some of which, such as the Sun, are surrounded by planets like Earth. Stars, in turn, cluster to form galaxies. As we shall discuss in Chapter 7, this clustering of matter reveals a great deal about the way different objects interact with one another.

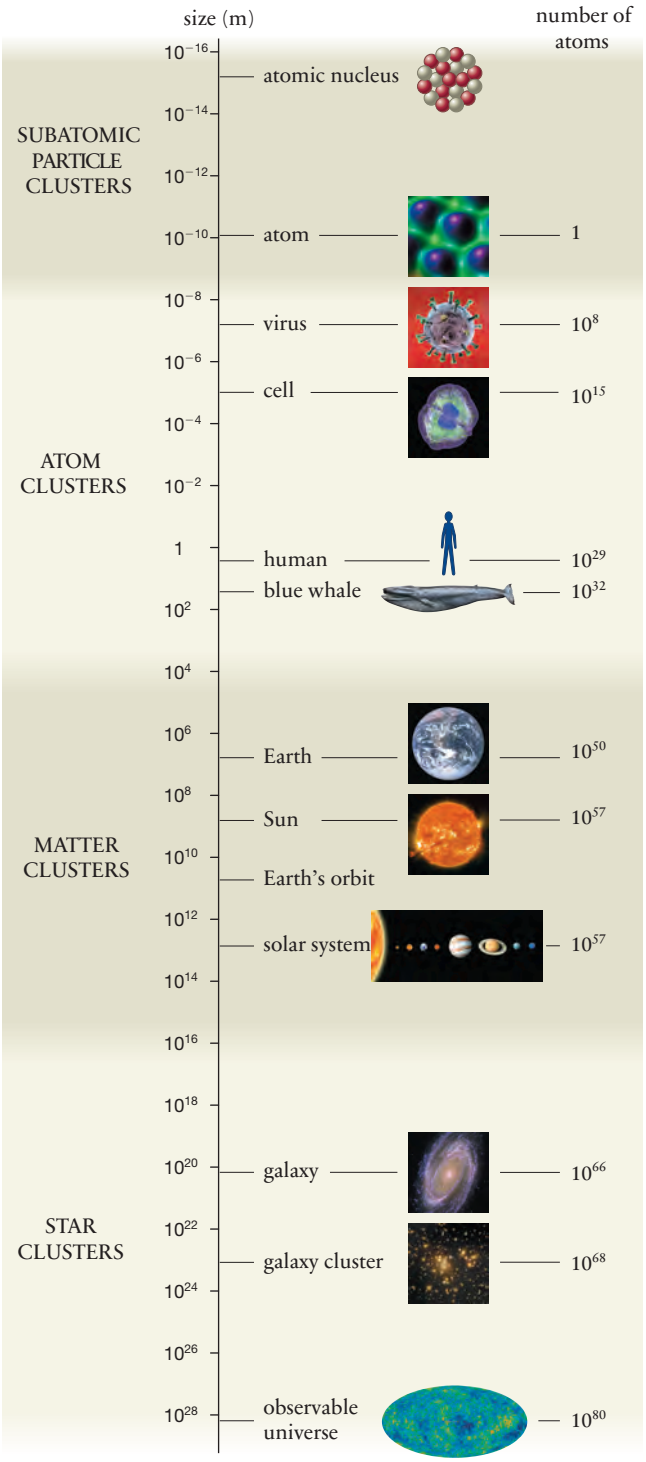
EXERCISE 1.4 Tiny universe

If all the matter in the observable universe were squeezed together as tightly as the matter in the nucleus of an atom, what order of magnitude would the diameter of the universe be?



SOLUTION From Figure 1.9 I see that there are about 10^{80} atoms in the universe. I can arrange these atoms in a cube that has 10^{27} atoms on one side because such a cube could accommodate $10^{27} \times 10^{27} \times 10^{27} = 10^{81}$ atoms. Given that the diameter of a nucleus is about 10^{-15} m, the length of a side of this cube would be

$$(10^{27} \text{ atoms})(10^{-15} \text{ m per atom}) = 10^{12} \text{ m},$$

which is a bit larger than the diameter of Earth's orbit around the Sun.

An alternative method for obtaining the answer is to realize that the matter in a single nucleus occupies a cubic volume of about $(10^{-15} \text{ m})^3 = 10^{-45} \text{ m}^3$. If all the matter in the universe were squeezed together just as tightly, it would occupy a volume of about 10^{80} times the volume of an atomic nucleus, or $10^{80} \times 10^{-45} \text{ m}^3 = 10^{35} \text{ m}^3$. The side of a cube of this volume is equal to the cube root of 10^{35} m^3, or 4.6×10^{11} m, which is the same order of magnitude as my first answer.

Figure 1.9 A survey of the size and structure of the universe.

1.6 Imagine magnifying each atom in an apple to the size of the apple. What would the diameter of the apple then be?

CONCEPTS

1.4 Time and change

Profound and mysterious, time is perhaps the greatest enigma in physics. We all know what is meant by *time,* but it is difficult, if not impossible, to explain the idea in words. (Put the book down for a minute and try defining *time* in words before reading on.) One way to describe time is that it is the infinite continual progression of events in the past, present, and future, often experienced as a force that moves the world along. This definition is neither illuminating nor scientifically meaningful because it merely relates the concept of time to other, even less well-defined notions. Time is defined by the rhythm of life, by the passing of days, by the cycle of the seasons, by birth and death. However, even though many individual phenomena, such as the 24-hour cycle of the days, the cycle of seasons, and the swinging of a pendulum, are repetitive, the time we experience does not appear to be repetitive, and in classical physics time is considered to be a continuous succession of events.

The irreversible flow of time controls our lives, pushing us inexorably forward from the past to the future. Whereas we can freely choose our location and direction in all three dimensions in space, time flows in a single direction, dragging us forward with it. Time thus presents less symmetry than the three dimensions of space: Although opposite directions in space are equivalent, opposite directions in time are not equivalent. The "arrow of time" points only into the future, a direction we define as the one we have no memory of. Curiously, most of the laws of physics have no requirement that time has to flow in one direction only, and it is not until Chapter 19 that we can begin to understand why events in time are essentially irreversible.

The arrow of time allows us to establish a *causal relationship* between events. For example, lightning causes thunder and so lightning has to occur *before* the thunder. This statement is true for all observers: No matter who is watching the storm and no matter where that storm is happening, every observer first sees a lightning bolt and only after that hears the thunder because an effect never precedes its cause. Indeed, the very organization of our thoughts depends on the **principle of causality:**

> **Whenever an event A causes an event B, all observers see event A happening first.**

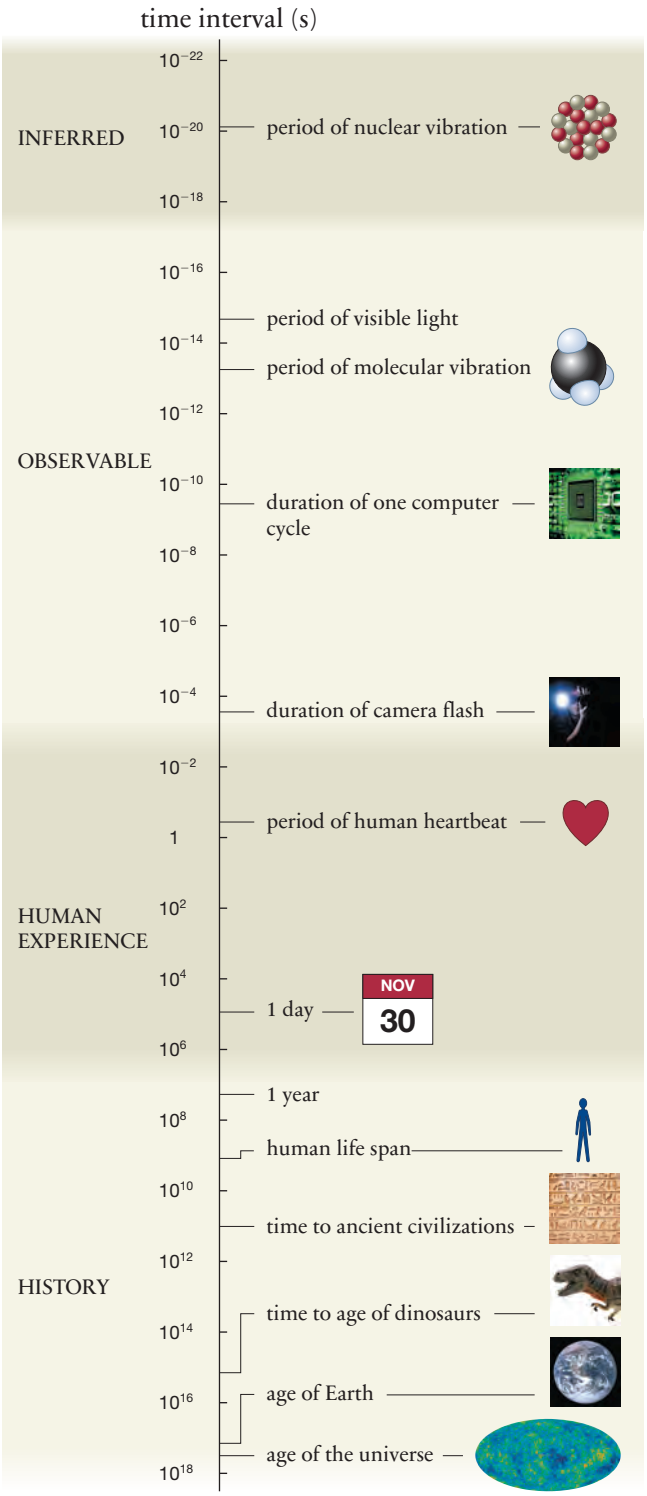
Without this principle, it wouldn't be possible to develop any scientific understanding of how the world works. (No physics course to take!) The principle of causality also makes it possible to state a definition: **Time** is a physical quantity that allows us to determine the sequence in which related events occur.

To apply the principle of causality and sort out causes and effects, it is necessary to develop devices—clocks—for keeping track of time. All clocks operate on the same principle: They repeatedly return to the same state. The rotation of Earth about its axis can serve as a clock if we note the instant the Sun reaches its highest position in the sky on successive days. A swinging pendulum, which repeatedly returns to the same vertical position, can also serve as a clock. The time interval between two events can be determined by counting the number of pendulum swings between the events. The accuracy of time measurements can be increased by using a clock that has frequent repetition of events.

1.7 (*a*) State a possible cause for the following events: (*i*) The light goes out in your room; (*ii*) you hear a loud, rumbling noise; (*iii*) your debit card is rejected at a store. (*b*) Could any of the causes you named have occurred after their associated event? (*c*) Describe how you feel when you experience an event but don't know what caused it—you hear a strange noise when camping, for instance, or an unexpected package is sitting on your doorstep.

The familiar standard unit for measuring time is the **second** (abbreviated s), originally defined as 1/86,400 of a day but currently more accurately defined as the duration of 9,192,631,770 periods of certain radiation emitted by cesium atoms. **Figure 1.10** gives an idea of the vast range of time scales in the universe.

The English physicist Isaac Newton stated, "Absolute, true, and mathematical time, of itself and from its own nature, flows equably without relation to anything external." In other words, the notion of past, present, and future is universal—"now" for you, wherever you are at this instant, is also "now" everywhere else in the universe. Although this notion of the universality of time, which is given the name **absolute time,** is intuitive, experiments described in Chapter 14 have shown this notion to be false. Still, for many experiments and for the material we discuss in most of this book, the notion of absolute time remains an excellent approximation.



Now that we have introduced space and time, we can use these concepts to study events. Throughout this book, we focus on **change,** the transition from one state to another. Examples of change are the melting of an ice cube, motion (a change in location), the expansion of a piece of metal, the flow of a liquid. As you will see, one might well call physics the study of the changes that surround us and convey the passage of time. What is most remarkable about all this is that we shall discover that underneath all the changes we'll look at, certain properties remain *unchanged*. These properties give rise to what are called *conservation laws,* the most fundamental and universal laws of physics.

There is a profound aesthetic appeal in knowing that symmetry and conservation are the cornerstones of the laws that govern the universe. It is reassuring to know that an elegant simplicity underlies the structure of the universe and the relationship between space and time.

CONCEPTS

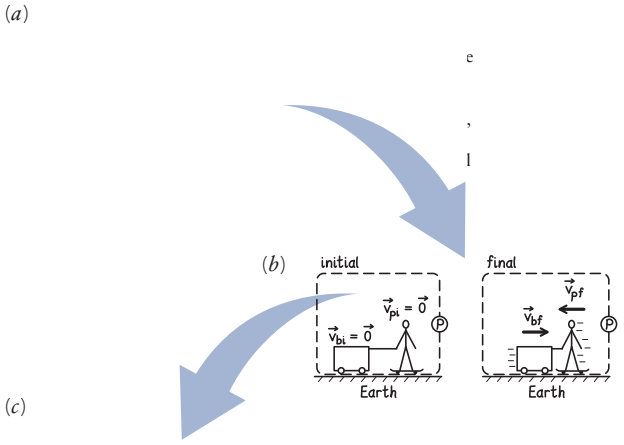
1.8 A single chemical reaction takes about 10^{-13} s. What order of magnitude is the number of sequential chemical reactions that could take place during a physics class?

Figure 1.10 A survey of the time scales on which events in the universe take place.

1.5 Representations

Of all our senses, vision may be the one that most informs our mind. For this reason, expert problem solvers rarely start working on a problem without first making some sort of visual representation of the available information, and you should always do the same. Such a drawing helps you establish a clear mental image of the situation, interpret the problem in light of your own knowledge and experience, develop a qualitative understanding of the problem, and organize the information in a meaningful way. Without the drawing, you have to juggle all the information in your head. The drawing frees your brain to deal with the solution. As an example, consider the situation described in Checkpoint 1.9. First try solving the problem without a piece of paper and note the mental effort it takes; then make a sketch and work out the solution.

1.9 You and your spouse are working out a seating arrangement around a circular table for dinner with John and Mary Jones, Mike and Sylvia Masters, and Bob and Cyndi Ahlers. Mike is not fond of the Ahlers, and Sylvia asked that she not be seated next to John. You would like to alternate men and women and avoid seating spouses next to each other. Determine an arrangement that satisfies all the constraints.



Were you able to solve the problem without a sketch? Doing so would be difficult because there is more information than most people can comfortably keep in mind at once. When you represent the information visually, however, it is relatively easy to solve this problem (see the solution in the back of this book). The drawing breaks the problem down into small steps and helps you articulate in your mind what you are trying to accomplish.

Visual representations are not helpful only for making seating arrangements. They work just as well for solving physics problems, although it may not immediately be clear *how* to represent the available information. For this reason we shall develop a number of different ways—pictures, sketches, diagrams, graphs—and a number of different context-specific procedures to represent information visually in our study of physics. As you will see, these visual representations are an integral part of getting a grip on a problem and developing a model (**Figure 1.11** on the next page).

As we discussed in Section 1.1, descriptions of the physical world always begin with simplified representations. When you solve physics problems, elaborate drawings clutter your mind with irrelevant information and prevent you from getting a clear view of the important features. One of the most basic skills in physics, therefore, is to decide what to leave out of your drawings. If you leave out essential features, the representation is useless, but if you put in too many details, it becomes impossible to analyze the situation.

CONCEPTS

Figure 1.11 Multiple representations help you solve problems. (*a*) Many problems start with a verbal representation. (*b*) Turning the words into a sketch helps you to grasp the problem. (*c*) The sketch can then give meaning to a mathematical representation of the problem.

Sometimes it is necessary to begin with an oversimplification in order to develop a feel for a given situation. Once this initial understanding has been gained, however, it becomes possible to construct less idealized models, with each successive model being a more realistic representation of the real-world situation.

In any drawings you make, therefore, you should treat everyday objects as simplifications that can be characterized by a minimum number of features or quantities. Some joke that physicists hold a grossly oversimplified view of the world, thinking in such terms as, for instance, "Consider a spherical cow. . . ." The world around us, cows included, contains infinitely many details that may play a role in the grand scheme of things, but to get a grip on any problem it is important to begin by leaving out as much detail as possible. If the resulting model reproduces the main features of the real world, you know you have taken the essential attributes into account. As an example, **Figure 1.12** shows a progression from a photograph of a cow to an abstract rendition of it. To study the pattern on the cow's hide, you need the photograph. If you are interested in only the position of a certain cow in a certain pasture, however, a simple dot suffices (Figure 1.12*d*). By reducing the cow to a dot, you have discarded any information about its size and shape, but as you will see as you continue with your study of physics, this information is often not relevant.

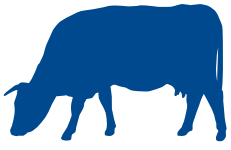
EXERCISE 1.5 Stretching a spring

For a physics laboratory assignment, one end of a spring is attached to a horizontal rod so that the spring hangs vertically, and a ruler is hung vertically alongside the spring. The stretching properties of the spring are to be measured by attaching eight identical beads to the spring's free end. With no beads attached, the free end of the spring is at a ruler reading of 23.4 mm. With one bead attached, the end of the spring drops to 25.2 mm. When the second, third, and fourth beads are attached one at a time, the end drops to ruler readings of 26.5 mm, 29.1 mm, and 30.8 mm, respectively. Adding the fifth and sixth beads together moves the spring end to 34.3 mm, and adding the last two beads moves the end to 38.2 mm. (*a*) Make a pictorial representation of this setup. (*b*) Tabulate the data. (*c*) Plot the data on a graph, showing the ruler readings on the vertical axis and the numbers of beads on the horizontal axis. (*d*) Describe what can be inferred from the data.

SOLUTION (*a*) The important items that should appear in my drawing are the spring, the rod from which it is suspended, the ruler, and at least one bead. My drawing should also indicate how the ruler readings are obtained. I can illustrate this procedure with just one bead, as **Figure 1.13*a*** shows. By drawing the spring first with no beads attached and then with one bead attached and showing the two ruler readings, I've represented the general procedure of adding beads one (or two) at a time and paying attention to how each addition changes the position of the spring end.

(*b*) See Figure 1.13*b*.

(*c*) See Figure 1.13*c*.



(*d*) The relationship between the ruler readings and the numbers of suspended beads is linear. That is to say, each additional bead stretches the spring by about the same amount.

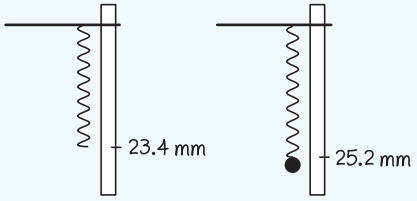
Figure 1.12 Increasingly simplified and abstract representations of a cow.

(*a*) Photograph

(*b*) Simplified sketch

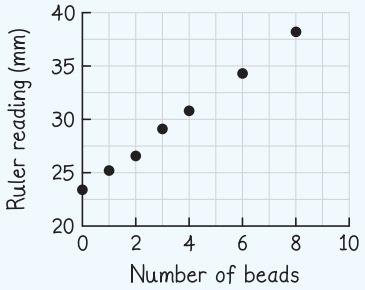
(*c*) Rectangle: represents cow's position and extent

(*d*) Dot: shows only cow's position



CONCEPTS

Figure 1.13



(a) Sketch

(b) Table

Number of beads	Ruler reading (mm)
0	23.4
1	25.2
2	26.5
3	29.1
4	30.8
6	34.3
8	38.2

(c) Graph

Exercise 1.5 demonstrates how various ways of representing information help you interpret data. The pictorial representation of Figure 1.13*a* helps you visualize how the measurements were taken. The table of Figure 1.13*b* organizes the data, and the graph of Figure 1.13*c* allows you to recognize the linear relationship between how far the spring stretches and the number of beads suspended from it—something that is not at all obvious from the text or the table.

Like the sketch, the graph is a simplified representation of the stretching of the spring. Each representation involves a loss of information and detail. The sketch is a simplified two-dimensional representation of a three-dimensional setup, and the graph shows only one piece of information for each measurement: the position of the bottom of the spring. All other information is left out in order to reveal one crucial point: How much the spring stretches is proportional to the number of beads suspended from it (something we look at in more detail in Chapter 9).

You may be beginning to wonder what the role of mathematics is in physics, given that we haven't used any thus far. One of the main roles of mathematics in physics is allowing us to express succinctly and unambiguously ideas that if expressed verbally would require a lot of words whose meaning may not be precise. Take this statement, for example:

> **The magnitude of the acceleration of an object is directly proportional to the magnitude of the vector sum of the forces exerted on the object and inversely proportional to the object's inertia. The direction of the acceleration is the same as the direction of the vector sum of the forces.**

(Don't worry about the meaning of this statement for now; just note that it is quite a mouthful.) We can express this statement mathematically as

$$\vec{a} = \frac{\Sigma \vec{F}}{m}.$$

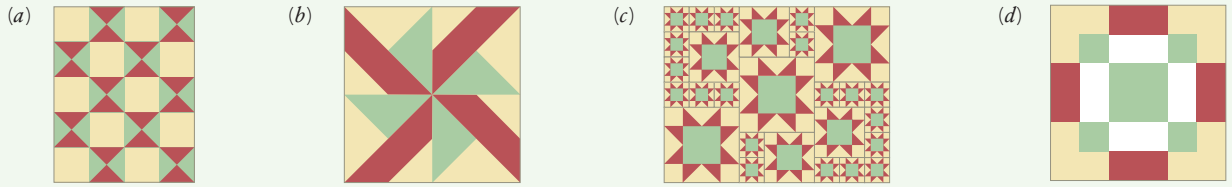
These two expressions—one verbal, the other mathematical—are identical. Neither one is more accurate than the other. Right now the symbols in the equation may make no more sense to you than hieroglyphs. Once you understand their meaning, however, the mathematical expression can be parsed much more quickly than the verbal expression can. In this respect, mathematics plays the same role as visual representations: It relieves the brain of having to keep track of many words. Another important benefit of mathematical representation is that we can use the techniques of mathematics to manipulate the symbols and obtain new insights.

Without an understanding of the meaning of the concepts in any expression (acceleration and force in our example here), however, verbal expressions and mathematical ones are both meaningless, and so it is important to focus first on the meanings of concepts. As you will notice, this book has been designed to develop concepts first and to emphasize the visual representation of these concepts before moving on to a mathematical treatment (see the box "Organization of this book," next page).

CONCEPTS

1.10 Picture a long, straight corridor running east-west, with a water fountain located somewhere along it. Starting from the west end of the corridor, a woman walks a short distance east along the corridor and stops before reaching the water fountain. The distance from her to the fountain is twice the distance she has walked. She then continues walking east, passes the water fountain, and stops 60 m from her first stop. Now the distance from her to the fountain is twice the distance from her to the east end of the corridor. How long is the corridor?

Organization of this book



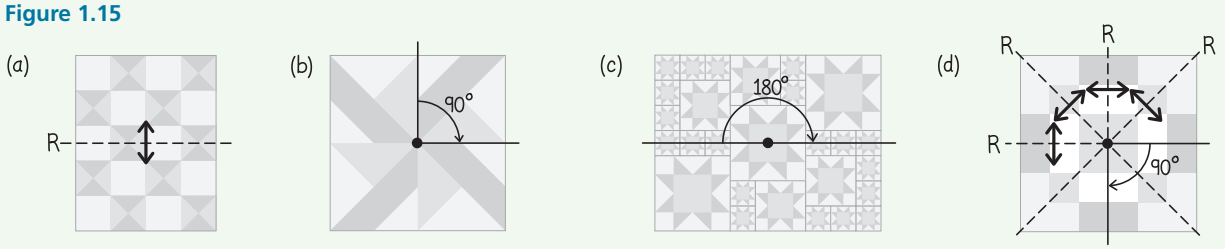
Each chapter is divided into two parts: *Concepts* and *Quantitative Tools*. The *Concepts* part develops the conceptual framework for the subject of the chapter, concentrating on the underlying ideas and helping you develop a mental picture of the subject. The *Quantitative Tools* part develops the mathematical framework, building on the ideas developed in the *Concepts* part. Interspersed in the text of each chapter are several types of learning aids to guide you through the chapter and a variety of questions and problems that allow you to apply and sharpen your understanding of physics:

1. **Checkpoints** (). These questions compel you to test yourself on how well you understand the material you just read. Do not skip them as you read the text. First of all, the answer to a checkpoint may be necessary to understand the text following that checkpoint. Second, and more important, I've put these checkpoints right in the text because working on them means learning the material. The answers to all the checkpoints are at the end of this book.
2. **Exercises and examples.** The fully-worked-out exercises and examples help you develop and apply problem-solving strategies. It is generally a good idea to attempt to solve the problem by yourself before reading the solution. More information on general approaches to problem solving is given in Section 1.8.
3. **Procedures.** Approaches for analyzing specific situations are given in separate, highlighted boxes.
4. **Self-quiz.** The Self-quiz in each chapter, which always comes at the end of the conceptual part of the chapter, allows you to assess your understanding of the concepts before you move on to the quantitative treatment. Complete each Self-quiz before working on the quantitative part of the chapter, even if you are already familiar with most of the material covered. Before tackling the quantitative material, be sure to resolve any difficulties you might have in answering a Self-quiz question, either by rereading the material in the conceptual part of the chapter or by consulting your instructor.
5. **Chapter summary.** The summary is just what the name implies, a condensed record of the key elements from the chapter.
6. **Questions and problems.** After working your way to this point, you should be ready to solve some problems on your own. These problems are both conceptual and quantitative, organized by chapter section and labeled with a rough "degree of difficulty" scale, indicated by one, two, or three dots. One-dot problems are fairly straightforward and usually involve only one major concept. Two-dot problems typically require you to put together two or more ideas from the chapter, or even to combine some element of the current chapter with material from other chapters. Three-dot problems are more challenging, or even a bit tricky. Some of these are designated as "CR" (context-rich), a category that is described later in this chapter. Context-rich problems are in the **Additional Problems** at the end of this section, together with other general problems.
7. **Glossary.** At the end of this book is a list defining the important concepts in each chapter (which are the terms printed in bold).

Self-quiz

1. Two children in a playground swing on two swings of unequal length. The child on the shorter swing is considerably heavier than the child on the longer swing. You observe that the longer swing swings more slowly. Formulate a hypothesis that could explain your observation. How could you test your hypothesis?
2. What symmetries do you observe in the quilt patterns of **Figure 1.14**?

Figure 1.14



3. Give the order of magnitude of these quantities in meters or seconds: (*a*) length of a football field, (*b*) height of a mature tree, (*c*) one week, (*d*) one year.
4. Starting from the first floor, an elevator stops at floors 5, 2, 4, 3, 6, and 4 (in that order) before returning to the first floor. (*a*) Represent this motion visually. (*b*) If the floors are evenly spaced and the distance between floors 1 and 6 is 15 m, what is the total distance traveled by the elevator?

Answers

1. One hypothesis is that longer swings swing more slowly than shorter swings. You can test this hypothesis by adjusting the length of either swing until the two lengths are the same and then asking the children to remount their respective swings and swing again. If the originally longer swing is still the slower one, your hypothesis is not correct. If the two swings now have the same speed, your hypothesis is correct. Another hypothesis is that heavier children swing faster than lighter ones. You can test this hypothesis by asking the children to trade places. If the longer swing now swings faster than the shorter swing, your hypothesis is correct. If the longer swing still swings more slowly, your hypothesis is incorrect.
2. See **Figure 1.15**. (*a*) Reflection symmetry about a horizontal line through the center. (*b*) Rotational symmetry by multiples of 90°. (*c*) Rotational symmetry by 180°. (*d*) Rotational symmetry by multiples of 90° and reflection symmetry about a horizontal, vertical, or diagonal line through the center.

Figure 1.15

3. (*a*) 100 yards is about 100 m; the order of magnitude is thus 100 m $= 10^2$ m. (*b*) An average mature tree is between 5 and 20 m tall, for an average of 12 m $= 1.2 \times 10^1$ m. The coefficient 1.2 rounds to 1, and so the order of magnitude is 1×10^1 m $= 10$ m. (*c*) 1 week $=$ (1 week)(7 days/week)(24 h/day) $\cdot$ (60 min/h)(60 s/min) $= 604{,}800$ s $= 6 \times 10^5$ s; the coefficient 6 rounds to 10, and so the order of magnitude is 10×10^5 s $= 10^6$ s. (*d*) 1 year $= 52$ weeks $=$ (52 weeks)(604,800 s/week) $= 31{,}449{,}600$ s $= 3.1 \times 10^7$ s; the coefficient 3.1 rounds to 10, and so the order of magnitude is 10×10^7 s $= 10^8$ s.
4. (*a*) See **Figure 1.16** for one way to represent the motion. Note that the elevator itself is not represented because showing it would add nothing we need to the visual information. The only thing we are interested in is distances traveled, represented by the vertical lines. (*b*) If the distance between floors 1 and 6 is 15 m, one floor is (15 m)/5 $= 3.0$ m. From the figure, I see that the numbers of floors traveled between successive stops are 4, 3, 2, 1, 3, 2, and 3, for a total of 18 floors, or 18(3.0 m) $= 54$ m.

1.6 Physical quantities and units

Because physics is a quantitative science, statements must be expressed in numbers, which requires either measuring or calculating numerical values for physical quantities. In this section we review some basic rules for dealing with physical quantities, which in this book are represented by italic symbols—typically letters from the Roman or Greek alphabet, such as t for time and σ for electrical conductivity. Table 1.1 gives the symbols for some of the physical quantities we use throughout the book.

Physical quantities are expressed as the product of a numerical value and a unit of measurement. For example, the length ℓ of an object that is 1.2 m long can be expressed as $\ell = 1.2$ m. The unit system used in science and engineering throughout the world and in everyday life in most countries is the Système International (International System), and the units are collectively called **SI units.** This system consists of seven base units (Table 1.2) from which all other units currently in use can be derived. For example, the physical quantity speed, which we discuss in Chapter 2, is defined as the distance traveled divided by the time interval over which the travel takes place. Thus the SI derived unit of speed is meters per second (m/s), the base unit of length divided by the base unit of time. A list of SI derived units and their relationship to the seven base units is given in Appendix C.

Be careful not to confuse abbreviations for units with symbols for physical quantities. Unit abbreviations are printed in roman (upright) type—m for meters, for instance—and symbols for physical quantities are printed in italic (slanted) type—t for time, say. Also, bear in mind that you can add and subtract quantities only if they have the same units; it is meaningless to add, say, 3 m to 4 kg.

To produce multiples of any SI unit and conveniently work with very large or very small numbers, we modify the unit name with prefixes representing integer powers of ten (Table 1.3). For example, a billionth of a second is denoted by 1 ns (pronounced "one nanosecond"):

$$1 \text{ ns} = 10^{-9} \text{ s}. \tag{1.1}$$

One thousand meters is denoted by 1 km, "one kilometer." Prefixes are never used without a unit and are never combined into compound prefixes. The unit *kilogram* contains a prefix (*kilo-*) because it is derived from the non-SI unit *gram* (1 kg = 1000 g). Therefore 10^{-6} kg never becomes 1 μkg. Instead, the names and multiples of the kilogram are constructed by adding the appropriate prefix to the word *gram* and the abbreviation g. For example, 10^{-6} kg becomes 1 mg, "one milligram."

The standard practice in engineering is to use only the powers of ten that are multiples of three.

Table 1.2 The seven SI base units

Name of unit	Abbreviation	Physical quantity
meter	m	length
kilogram	kg	mass
second	s	time
ampere	A	electric current
kelvin	K	thermodynamic temperature
mole	mol	amount of substance
candela	cd	luminous intensity

Table 1.3 SI prefixes

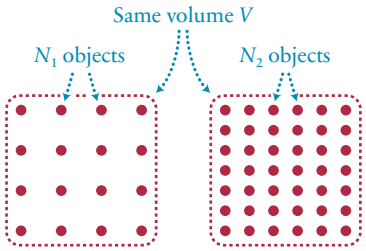
10^n	Prefix	Abbreviation	10^n	Prefix	Abbreviation
10^0	—	—			
10^3	kilo-	k	10^{-3}	milli-	m
10^6	mega-	M	10^{-6}	micro-	μ
10^9	giga-	G	10^{-9}	nano-	n
10^{12}	tera-	T	10^{-12}	pico-	p
10^{15}	peta-	P	10^{-15}	femto-	f
10^{18}	exa-	E	10^{-18}	atto-	a
10^{21}	zetta-	Z	10^{-21}	zepto-	z
10^{24}	yotta-	Y	10^{-24}	yocto-	y

1.11 Use prefixes from Table 1.3 to remove either all or almost all of the zeros in each expression. (*a*) $\ell = 150{,}000{,}000$ m, (*b*) $t = 0.000\ 000\ 000\ 012$ s, (*c*) 1200 km/s, (*d*) 2300 kg.

Of the seven SI base units, we have already discussed two, the meter and the second. We discuss the base unit for mass, the kilogram, in Chapter 4, the base unit for electric current, the ampere, in Chapter 27, and the base unit for temperature, the kelvin, in Chapter 20.

The **mole** (abbreviated mol) is the SI base unit that measures the quantity of a given substance. A mole is approximately the number of atoms in 12×10^{-3} kg of carbon-12, the most common form of carbon. This number is called **Avogadro's number** N_A, after the 19th-century Italian physicist Amedeo Avogadro. In the SI system, Avogadro's number is defined to be exactly

$$N_A \equiv 6.02214076 \times 10^{23}. \tag{1.2}$$



Note that the mole is simply a number: Just as *one dozen* means 12 of anything and *one gross* means 144 of anything, *one mole* means 6.022×10^{23} of anything. So 1 mol of helium atoms is 6.022×10^{23} helium atoms, and 1 mol of carbon dioxide molecules is 6.022×10^{23} carbon dioxide molecules.

The final SI base unit, the *candela,* measures luminous intensity. One candela (1 cd) is roughly the amount of light generated by a single candle; the light emitted by a 100-watt light bulb is about 120 cd. The definition of the candela takes into account how the human eye perceives the intensity of various colors and is therefore rather unwieldy. For this reason we do not use the candela in this book in the chapters dealing with light, concentrating instead on the amount of energy carried by light.

An important concept used throughout physics is **density,** the physical quantity that measures how much of some substance there is in a given volume. Depending on the quantity being measured, there are various types of density. For example, *number density* is the number of objects per unit volume. If there are N objects in a volume V, then the number density n of these objects is

$$n \equiv \frac{N}{V}. \tag{1.3}$$

Figure 1.17 Number density.

The greater the number N of objects in a given space V, the higher the number density $n = N/V$. In this case $N_2 > N_1$, so $n_2 > n_1$.

(The symbol $\equiv$ means that the equality is either a definition or a convention.) If the objects in a given volume are packed together more tightly, the number density is higher (**Figure 1.17**). *Mass density* ρ (Greek rho) is the amount of mass m per unit volume:

$$\rho \equiv \frac{m}{V}. \tag{1.4}$$

EXERCISE 1.6 Helium density

At room temperature and atmospheric pressure, 1 mol of helium gas has a volume of 24.5×10^{-3} m^3. The same amount of *liquid* helium has a volume of 32.0×10^{-6} m^3. What are the number and mass densities of (*a*) the gaseous helium and (*b*) the liquid helium? The mass of one helium atom is 6.647×10^{-27} kg.

SOLUTION (*a*) I know from Eq. 1.2 that 1 mol of helium contains 6.022×10^{23} atoms, and I can use this information in Eq. 1.3 to get the number density:

$$n = \frac{6.022 \times 10^{23} \text{ atoms}}{24.5 \times 10^{-3} \text{ m}^3} = 2.46 \times 10^{25} \text{ atoms/m}^3.$$

For the mass density, I must know the mass of 1 mol of helium atoms, and so I multiply the mass of one helium atom by the number of atoms in 1 mol:

$$m = (6.647 \times 10^{-27} \text{ kg/atom})(6.022 \times 10^{23} \text{ atoms/mol})$$

$$= 4.003 \times 10^{-3} \text{ kg/mol}.$$

Equation 1.4 then yields

$$\rho = \frac{4.003 \times 10^{-3} \text{ kg}}{24.5 \times 10^{-3} \text{ m}^3} = 0.163 \text{ kg/m}^3.$$

(*b*) For the liquid helium, the same reasoning gives me

$$n = \frac{6.022 \times 10^{23} \text{ atoms}}{32.0 \times 10^{-6} \text{ m}^3} = 1.88 \times 10^{28} \text{ atoms/m}^3$$

$$\rho = \frac{4.003 \times 10^{-3} \text{ kg}}{32.0 \times 10^{-6} \text{ m}^3} = 125 \text{ kg/m}^3.$$

Examples of non-SI units accepted for use along with SI units are the minute (1 min = 60 s), the hour (1 h = 3600 s), the liter (1 L = 10^{-3} m^3), and the metric ton (1 t = 10^3 kg).

A number of traditional, non-SI units are used in engineering; in various businesses, industries, sports, and trades; and in everyday life in the United States. Examples are inches, feet, yards, miles, acres, ounces, pints, gallons, and fluid ounces. These units are nondecimal, which makes it hard to interconvert them. When solving problems in this course, always begin by converting any quantities given in non-SI units to the SI equivalents. A conversion table is given in Appendix C.

The simplest way to convert from one unit to another is to write the conversion factor for the two units as a ratio. For example, in Appendix C, we see that 1 in. = 25.4 mm. By bringing the 25.4 mm to the left side of the equals sign, we can write this as either

$$\frac{1 \text{ in.}}{25.4 \text{ mm}} = 1 \quad \text{or} \quad \frac{25.4 \text{ mm}}{1 \text{ in.}} = 1. \tag{1.5}$$

Note that you *must* write the units in these expressions because without them you obtain the incorrect expressions $\frac{1}{25.4} = 1$ and $\frac{25.4}{1} = 1$. Because multiplying any number by 1 doesn't change the number, you can use these ratios to convert units. For example, to express 4.5 in. in millimeters, you multiply by the ratio on the right in Eq. 1.5 and cancel out the inches:

$$4.5 \text{ in.} = (4.5 \cancel{\text{in.}})\left(\frac{25.4 \text{ mm}}{1 \cancel{\text{in.}}}\right) = 4.5 \times 25.4 \text{ mm} = 1.1 \times 10^2 \text{ mm}. \qquad (1.6)$$

1.12 Why is the ratio on the left in Eq. 1.5 not suitable for converting inches to millimeters?

EXERCISE 1.7 Unit conversions

Convert each quantity to a quantity expressed either in meters or in meters raised to some power: (*a*) 4.5 in., (*b*) 3.2 acres, (*c*) 32 mi, (*d*) 3.0 pints.

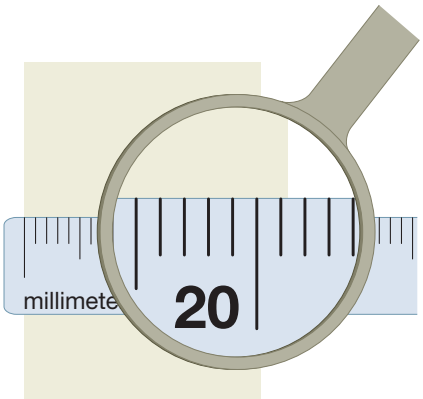
SOLUTION I obtain my conversion factors from Appendix C.

(*a*) $$(4.5 \text{ in.})\left(\frac{2.54 \times 10^{-2} \text{ m}}{1 \text{ in.}}\right) = 1.1 \times 10^{-1} \text{ m}.$$

(*b*) $$(3.2 \text{ acres})\left(\frac{4.047 \times 10^3 \text{ m}^2}{1 \text{ acre}}\right) = 1.3 \times 10^4 \text{ m}^2.$$

(*c*) $$(32 \text{ mi})\left(\frac{1.609 \times 10^3 \text{ m}}{1 \text{ mi}}\right) = 5.1 \times 10^4 \text{ m}.$$

(*d*) $$(3.0 \text{ pints})\left(\frac{4.732 \times 10^{-4} \text{ m}^3}{1 \text{ pint}}\right) = 1.4 \times 10^{-3} \text{ m}^3.$$



1.13 (*a*) Using what you know about the diameters of atoms from Section 1.3, estimate the length of one side of a cube made up of 1 mol of closely packed carbon atoms. (*b*) The mass density of graphite (a form of carbon) is 2.2×10^3 kg/m^3. By how much does the length you calculated in part *a* change when you do your calculation with this mass density value? Remember that 1 mol is approximately the number of atoms in 12×10^{-3} kg of carbon.

1.7 Significant digits

The numbers we deal with in physics fall into two categories: exact numbers that are known with complete certainty (integers, such as the 14 in "I have 14 books on my desk") and inexact numbers that result from measurements and are known to only within some finite precision. Consider, for example, using a ruler to measure the width of a piece of paper (**Figure 1.18**). The width falls between the ruler marks for 21 mm and 22 mm and is closer to 21 mm than 22 mm. We might guess that the width is about 21.3 mm, but we cannot be sure about the last digit without a better measurement method. By recording the width as 21 mm, we are indicating that the width actually lies between 20.5 mm and 21.5 mm. The value 21 mm is said to have two **significant digits**—digits that are known reliably.

By expressing a value with the proper number of significant digits, we can convey the precision to which that value is known. For numbers that don't contain any zeros, all digits shown are significant, which means that 21 has two significant digits, as just noted, and 21.3 has three significant digits (implying that the value lies between 21.25 and 21.35).

Figure 1.18 If you measure the width of a sticky note with the ruler shown, you can reliably read off two digits.

With numbers that contain zeros, the situation is more complicated. *Leading zeros,* which means any that come before the first nonzero digit, are never significant: 0.037 has two significant digits. Zeros that come between two nonzero digits, as in 0.602, are always significant. *Trailing zeros* are those that come after the last nonzero digit in a number, as in 3.500 and 20. Trailing zeros to the right of the decimal point are always significant: 25.10 has four significant digits. However, trailing zeros in numbers that do not contain a decimal point are ambiguous. For example, in the number 7900, it is not clear whether the trailing zeros are significant or not. The number of significant digits is at least two but could be three or four. To accurately convey the precision for such numbers, we use scientific notation, which lets us place significant zeros to the right of the decimal point: 7.900×10^3 has four significant digits, 7.90×10^3 has three, and 7.9×10^3 has two.

Important note: To simplify the notation in this book, we consider all trailing zeros in numbers that do not contain a decimal point to be significant: four significant digits for 3400, for instance, and two significant digits for 30.

Do not confuse significant digits with the number of decimal places or the number of digits: 0.000584 has three significant digits, six decimal places, and seven digits; 58.4 has three significant digits, one decimal place, and three digits. With the exception of fundamental constants such as the speed of light, most values in this book are given to two or three significant digits.

When you use a calculator for the math involved in solving physics problems, the calculator display usually shows many more digits than the number of significant digits allowed by the problem data. In such cases, you need to round your answer to the correct number of significant digits. If the digit just to the right of the last significant digit you are allowed is less than 5, report your last significant digit as it appears on the calculator display. If the digit just to the right of the last significant digit is 5 or greater, increase your last significant digit by 1. For example, if you are allowed two significant digits, 1.356 rounds to 1.4, 2.5199 rounds to 2.5, and 7.95 rounds to 8.0.

Multiple roundings can yield an accumulation of errors, and therefore it is best to wait until you have obtained the final result in a multistep calculation before rounding. In intermediate results, therefore, retain a few more digits than what your input quantities have and then round off to the correct number of significant digits only in your final result.

EXERCISE 1.8 Significant digits

(*a*) How many significant digits are there in 403.54 kg, 3.010×10^{57} m, 2.43×10^{-3} s, 14.00 μm, 0.0140 s, 5300 kg? (*b*) Round 12,300 kg and 0.0125 s to two significant digits.

SOLUTION (*a*) 403.54 kg has five, 3.010×10^{57} m has four, 2.43×10^{-3} s has three, 14.00 μm has four, 0.0140 s has three, 5300 kg has four in this book (but is considered ambiguous in general).

(*b*) 1.2×10^4 kg (or 12 Mg); 0.013 s (or 1.3×10^{-3} s or 1.3 ms).

Suppose you measure the mass and volume of some object to be $m = 1.2$ kg and $V = 0.123$ m^3, and you wish to use these values to compute the object's mass density. If you substitute the measured values into Eq. 1.4 and carry out the division on your calculator, you get

$$\rho \equiv \frac{m}{V} = \frac{1.2 \text{ kg}}{0.123 \text{ m}^3} = 9.756\,097\,56 \text{ kg/m}^3. \tag{1.7}$$

You measured the mass to two significant digits and the volume to three significant digits, but your calculator suggests you have determined the density to a precision of better than one part in a billion! The rigorous way to deal with uncertainties in measurements is to recalculate any computed value by using the high and low uncertainties for each value in the calculation, which is a time-consuming task. For this reason, we shall use two shortcuts. The first deals with multiplication and division:

When multiplying or dividing quantities, the number of significant digits in the result is the same as the number of significant digits in the input quantity that has the fewest significant digits.

In your calculation of the mass density in Eq. 1.7, the input quantity that has the fewest significant digits is the mass (two significant digits), and so the answer should be rounded to two significant digits:

$$\rho \equiv \frac{m}{V} = \frac{1.2 \text{ kg}}{0.123 \text{ m}^3} = 9.8 \text{ kg/m}^3. \tag{1.8}$$

Now suppose you determine the mass of two parts of an object and obtain 105 kg for one part and 0.01 kg for the other (three and one significant digit, respectively). Adding the two measured values yields a value containing five significant digits:

$$105 \text{ kg} + 0.01 \text{ kg} = 105.01 \text{ kg}. \tag{1.9}$$

Given that the precision in the value 105 kg is ± 0.5 kg, it makes no sense to report the final result to five significant digits. Rounding so that the number of significant digits in the sum is the same as the number of significant digits in the input value that has the fewest significant digits would yield 100 kg, which deviates from the "actual" value (around 105 kg) by significantly more than the precision in the individual measurements (± 0.5 kg and ± 0.005 kg). To solve this problem, whenever we add or subtract numerical values, we focus on the number of *decimal places*:

When adding or subtracting quantities, the number of decimal places in the result is the same as the number of decimal places in the input quantity that has the fewest decimal places.

For the addition in Eq. 1.9, the input quantity that has the fewest decimal places is 105 kg (zero decimal places), and so

$$105 \text{ kg} + 0.01 \text{ kg} = 105 \text{ kg}. \tag{1.10}$$

Bear in mind that *counting numbers* (that is, integers) are exact and so have an infinite number of significant digits. For example, the product of the width of two buttons each 15.7 mm wide is $2 \times 15.7 \text{ mm} = 31.4 \text{ mm}$ (not 3×10^1 mm because the 2 is a counting number).

EXERCISE 1.9 Significant digits and calculations

Calculate: (*a*) $f = a/(bc)$, where $a = 2.34 \text{ mm}^2$, $b = 54.26$ m, and $c = 0.14$ μm; (*b*) $g = kt^3$, where $k = 1.208 \times 10^{-2} \text{ s}^{-3}$ and $t = 2.84$ s; (*c*) $f + g$; (*d*) the sum of $b = 54.26$ m and $c = 1.4$ mm; (*e*) $h = k(m - n)$, where $k = 1.252$, $m = 32.21$, and $n = 32.1$.

(Continued)

SOLUTION (*a*) I first need to convert the millimeters-squared in $a = 2.34\ \text{mm}^2$ to meters-squared and the micrometers in $c = 0.14\ \mu\text{m}$ to meters:

$$2.34\ \text{mm}^2\left(\frac{1\ \text{m}}{1\times10^3\ \text{mm}}\right)^2 = 2.34\ \text{mm}^2\left(\frac{1\ \text{m}^2}{1\times10^6\ \text{mm}^2}\right) = 2.34\times10^{-6}\ \text{m}^2$$

$$0.14\ \mu\text{m}\left(\frac{1\ \text{m}}{1\times10^6\ \mu\text{m}}\right) = 0.14\times10^{-6}\ \text{m}.$$

Substituting the values given, I get

$$f = \frac{2.34\times10^{-6}\ \text{m}^2}{(54.26\ \text{m})\,(0.14\times10^{-6}\ \text{m})} = 0.30804,$$

which I must round to two significant digits, 0.31, because that is the number of significant digits in the value given for *c*.

(*b*) $g = (1.208\times10^{-2}\ \text{s}^{-3})(2.84\ \text{s})^3 = 0.2767$, which I must round to three significant digits, 0.277, because of *t*.

(*c*) $f + g = 0.30804 + 0.2767 = 0.58474$, which I round to 0.58 because I must report only two decimal places, limited by $c = 0.14\ \mu\text{m}$. Note that if I had added the rounded values for *f* and *g*, my result reported to two significant digits would not be 0.58: $f + g = 0.31 + 0.277 = 0.587$, which rounds to 0.59. Be careful—reporting the correct number of significant digits can be tricky.

(*d*) $b + c = 54.26\ \text{m} + 0.0014\ \text{m} = 54.26\ \text{m}$ (reported to two decimal places, limited by the 54.26 value).

(*e*) $h = 1.252(32.21 - 32.1) = 0.1$ (reported to one significant digit, limited by the 32.1 value).

The number zero requires special consideration. When some physical quantity (other than temperature) is exactly zero, we denote this quantity by a zero *without units*. The speed of an object that is not moving is exactly zero and is therefore denoted by $v = 0$ (no units). However, if we measure a speed as zero to two significant digits, we write $v = 0.0\ \text{m/s}$ (note the units), implying that the value is zero to within 0.05 m/s.

1.14 (*a*) Express the circumference of a circle of radius $R = 27.3$ mm with the correct number of significant digits. (*b*) Let $a = 12.3$, $b = 3.241$, and $c = 55.74$. Compute $a + b + c$. (*c*) Let $m = 4.00$, $n = 3.00$, and $k = 7$ (exact). Compute $f = m^2/k$, $g = n^2/k$, and $f + g$.

1.8 Solving problems

You encounter problems every day. You are in a rush to get somewhere but can't find your car keys. You run out of flour while baking a birthday cake, and the supermarket is closed. Your flight is canceled on your way to a job interview. You want to buy those great new shoes, but there's no money in the bank. There is no formula for solving these or any other types of problems (if there were a formula, you wouldn't have a problem!). Because real-world problems defy one-shot solutions, we must break them down into smaller parts and solve them in steps. In this section we develop a four-step problem-solving strategy that will help you tackle a broad variety of problems (the procedure is summarized in the box "Solving problems" on page 41).

Most physics problems are formulated in words. This is true not only of the problems in this book but also of questions you might have about the world around you. Standing on the rim of the Grand Canyon, you might wonder, If I drop a stone, how long does it take to hit the bottom?, or while watching the Olympics, you might wonder, Is there a physical limit to how high an athlete can jump?

❶ GETTING STARTED

Because it's not clear which road leads you most efficiently to the answer to a given problem, the first step of our problem-solving strategy, *getting started,* is the most difficult one. It is therefore useful to begin with something you *can* do: Organize the information given and be sure you are clear on exactly what is asked for in the problem. To clarify the goal of the problem in your mind, it is crucial to begin by visualizing the situation: Sketch, describe in your own words, list, and/or tabulate the main features of the problem to relieve yourself from having to hold all this information in memory. In making a sketch, be sure to follow the guidelines given in Section 1.5: Make your rendering as simple as possible and show all relevant numerical information in the sketch. Recasting your problem visually or verbally forces you to spell out what you want to accomplish and often automatically leads to ideas on how to solve the problem.

Once you have the information organized, ask yourself which concepts and principles apply. Throughout this book, we develop principle-specific procedures for solving problems. By determining which principles apply to a problem you are working on, you can identify which problem-solving procedures apply to your problem.

Finally, you must determine whether or not you have all the information necessary to solve the problem. Sometimes you may have to supplement the information provided with things you know about the situation at hand. Furthermore, because no problem can be formulated with absolute precision, you will often need to make a number of simplifying assumptions. This lack of precision is often a source of frustration for anyone beginning to solve physics problems. How do you know which assumptions are valid for a given problem? Do not let this question trouble you—as long as you are aware of the assumptions you make, you can always reexamine them once you have obtained an answer and then refine the assumptions and the solution.

❷ DEVISE PLAN

Next you must *devise a plan* for solving your problem, which means spelling out what you must do to solve the problem. Are there any physical relationships or equations that you can apply to determine the information you are trying to obtain? A good plan is to outline the steps you need to take to obtain a solution. For some (but certainly not all) problems, these steps are carried out mathematically.

❸ EXECUTE PLAN

In the third step, you *execute your plan* by following the steps you have outlined, substituting the information given and carrying out any mathematical operations necessary to isolate the quantity you wish to determine. In problems involving numerical values, you should solve for an algebraic answer first, waiting until the final step to substitute numerical values and obtain a numerical answer. The only exception to this algebraic-answer-first approach is that, in order to simplify your algebraic expressions, you should eliminate any quantities that are zero from them as soon as possible.

In the final step, substituting numerical values into your algebraic expression, do not forget to show the correct units on all numerical values and to carry these units through the calculation.

Once you have obtained an answer, you should check your work for these five important points (which you can remember via the acronym *VENUS*):

1. **V**ectors/scalars used correctly? As you will see in Chapter 2, the quantities we deal with in this book fall into two classes, vectors and scalars. Make sure you have expressed your answer in the appropriate form. (In this chapter all quantities are scalars.)
2. **E**very question asked in problem statement answered? Reread the problem statement to make sure you have completely answered every question.
3. **N**o unknown quantities in answers? If your answer is an algebraic expression, be sure that every variable appearing in terms to the right of the equals sign has been given as a known quantity in the problem statement. Example: "A car moving at speed v . . . " means that v in this problem is a known quantity.
4. **U**nits correct? Each numerical answer should be expressed as a number with the appropriate units for that quantity (Section 1.6). When your answer is an algebraic expression, be sure that the combined units of all terms to the right of the equals sign work out to be equivalent to the unit of the quantity to the left of the equals sign.
5. **S**ignificant digits justified? The number of significant digits reported in your answer should reflect the number of significant digits of the quantities given in the problem statement (Section 1.7).

As a reminder to yourself, put a checkmark beside each answer to indicate that you checked these five points.

❹ EVALUATE RESULT

You may think you are done, but there is one final—and very important—step left: *Evaluate your answer*. In this step, you should reflect on your work, examine the result, and determine whether your answer is reasonable (or, if you can't tell whether or not it is reasonable, at least make sure that it is not unreasonable). The first thing you might try is seeing whether your answer conforms to what you expect based on your situation sketch, diagram, or other information given. If any part of your answer is unexpected, go back and check your math and any assumptions you made.

If your result is an algebraic expression or if your numerical answer comes directly from an algebraic expression, check whether or not that expression behaves as you expect with changes in physical quantities. For example, say you obtain the expression $v = k/t$ for the speed of an object and you know from experience that for this object the speed is zero for large values of t. If you let t go to infinity, your expression should indeed give the right answer: $v = k/\infty = 0$. If it didn't, you must go back and check your math and any assumptions you made.

Some problems can be solved in more than one way. If you solve your problem in two ways and obtain the same answer, you can be pretty sure your answer is correct. If you don't get the same answer from the two ways, you'd better go back and check your work!

If none of the evaluation methods can be applied to your answer, you should at least verify that there is nothing obviously wrong with it by checking that the algebraic signs you obtain make sense and that any numerical value has the correct order of magnitude. For example, if the algebraic sign of your solution tells you that an object moves to the left when you know it should move to the right, you know your answer can't be right. You can find some techniques for estimating orders of magnitude

PROCEDURE: Solving problems

Although there is no set approach when solving problems, it helps to break things down into several steps whenever you are working a physics problem. Throughout this book, we use the four-step procedure summarized here to solve problems. For a more detailed description of each step, see Section 1.8.

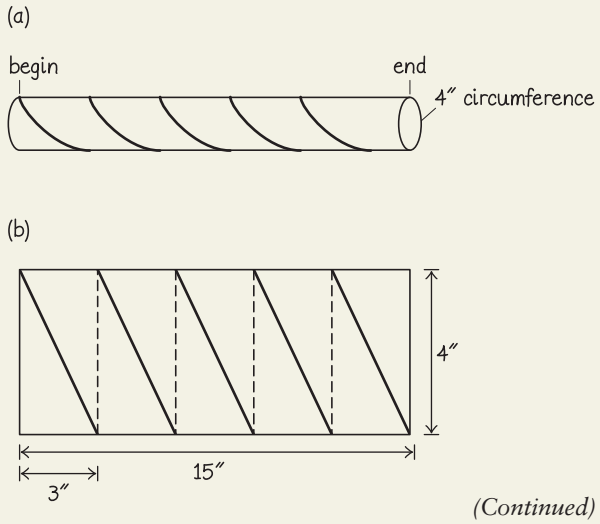
1. **Getting started.** Begin by carefully analyzing the information given and determining in your own words what question or task is being asked of you. Organize the information by making a sketch of the situation or putting data in tabular form. Determine which physics concepts apply, and note any assumptions you are making.
2. **Devise plan.** Decide what you must do to solve the problem. First determine which physical relationships or equations you need, and then determine the order in which you will use them. Make sure you have a sufficient number of equations to solve for all unknowns.
3. **Execute plan.** Execute your plan, and then check your work for the following five important points:

   Vectors/scalars used correctly?
   Every question asked in problem statement answered?
   No unknown quantities in answers?
   Units correct?
   Significant digits justified?

   As a reminder to yourself, put a checkmark beside each answer to indicate that you checked these five points.
4. **Evaluate result.** There are several ways to check whether an answer is reasonable. One way is to make sure your answer conforms to what you expect based on your sketch and the information given. If your answer is an algebraic expression, check to be sure the expression gives the correct trend or answer for special (limiting) cases for which you already know the answer. Sometimes there may be an alternative approach to solving the problem; if so, use it to see whether or not you get the same answer. If any of these tests yields an unexpected result, go back and check your math and any assumptions you made. If none of these checks can be applied to your problem, check the algebraic signs and order of magnitude.

in the next section. Using these techniques, you should be able to obtain reasonable upper and lower bounds for your answer. Provided your answer does not lie outside this range, you know there is not something obviously wrong with it.

With the exception of one-step exercises that are applications of procedures, the examples in this book follow this four-step procedure.



EXAMPLE 1.10 Length of string

A certain cylinder is 15 in. long and has a circumference of 4.0 in. When one end of a piece of string is attached to the left end of the cylinder and the string is then wound exactly five times around, the string just reaches to the cylinder's right end. What is the length of the string?

❶ **GETTING STARTED** I begin by making a sketch of the situation (**Figure 1.19*a***). The shortest length is going to be obtained when the string is wound uniformly, with each of the five windings running one-fifth of the length of the cylinder. I need to find a way to determine the length of this spiraling string. This appears to be a geometry problem, but the surface of the cylinder is curved, not flat.

❷ **DEVISE PLAN** If I imagine drawing a straight line between the endpoints of the string, cutting the cylinder surface along that line, and then flattening the cylinder out, I obtain the situation shown in Figure 1.19*b*. Now the solution is clear: The total length of the string is the sum of the hypotenuses of five identical triangles.

Figure 1.19

(Continued)

❸ **EXECUTE PLAN** The width of each triangle is equal to one-fifth of the length of the cylinder: $(15 \text{ in.})/5 = 3.0 \text{ in.}$ The height of each triangle is equal to the circumference of the cylinder (4.0 in.). With these values, I can now use the Pythagorean theorem to determine the length ℓ of the hypotenuse of each triangle:

$$\ell = \sqrt{(3.0 \text{ in.})^2 + (4.0 \text{ in.})^2} = 5.0 \text{ in.}$$

The length of the string is equal to five times this value, or 25 in. ✔*

❹ **EVALUATE RESULT** The answer I obtain should be larger than the string length I would obtain if the string were wound around the cylinder in one place, which would give a string length of five times the circumference: $5 \times 4.0 \text{ in.} = 20 \text{ in.}$ My answer should be smaller than what I would get if the string were wound five times around the cylinder at one end and then run along the cylinder length to the other end, which would give a string length of five times the circumference plus the length of the cylinder: $(5 \times 4.0 \text{ in.}) + 15 \text{ in.} = 35 \text{ in.}$ The answer I obtained does indeed lie between these values, giving me confidence that it is correct.

*The checkmark shows that I checked my answer regarding the five important details listed on page 40: Vector/scalar: all quantities scalar; Every question answered: yes; No unknown quantities in answers: no; Units correct: yes, inches; Significant digits: everything given to two significant digits.

1.9 Developing a feel

Making order-of-magnitude estimates is possibly the most important skill to retain from a physics course because this is a skill you will use long after you leave your last classroom, no matter what you plan for a career. Economists, for instance, carry out order-of-magnitude estimates to predict market trends, and business owners might carry out such estimates to validate a business plan, to name just two possibilities.

Here in this physics course, to get back to the present, order-of-magnitude estimates allow you to develop a feel for a problem before you try to solve it. They also allow you to validate your answer: If your order-of-magnitude estimate and your answer disagree, you know to go back and reevaluate your work.

Order-of-magnitude estimates involve determining relationships between known and unknown quantities, making gross oversimplifications, combining assumptions and ideas, and even outright guessing. In general, there are multiple ways to obtain such estimates. The uncertainty in how to carry out an estimate is intimidating at first, and the lack of accuracy may appear unscientific to you. It isn't—estimation is an important aspect of science, and it is a great way to obtain physical insight and at the same time train your analytical and outside-the-box thinking skills.

For example, suppose we need to determine the number of cells in the human body. That we can't see individual cells tells us they must be very small, and therefore the number is probably very large. We could *guess* the number of cells, but the answer would probably be meaningless because we have no way of assessing its accuracy without looking it up somewhere. A billion? Ten billion? Hundred billion? What do you think?

To obtain an order-of-magnitude estimate, the first thing to do is to think of a strategy. For the number of cells in the human body, for example, if we knew the volume of a typical human body and the volume of a typical cell, we could divide the former by the latter to obtain our answer. Knowing neither volume, however, we need to estimate both.

There are several ways to estimate the volume of the human body. One way is to model the body as a cylinder (**Figure 1.20**). For the height of the cylinder, we take the height of a typical human, say $h_{\text{human}} \approx 1.7$ m. The symbol $\approx$ indicates that this value is an approximation. For the diameter, we take $d_{\text{human}} \approx 0.2$ m. That makes the diameter less than the left-to-right thickness of the body but greater than the front-to-back thickness, which should be in the right ballpark. This gives a volume of

$$V_{\text{human}} = \left(\frac{1}{4}\pi d_{\text{human}}^2\right) h_{\text{human}} \approx 0.05 \text{ m}^3.$$

Figure 1.20 To determine the volume of the human body, we approximate the body as a cylinder.

QUANTITATIVE TOOLS

Another way is to realize that the human body has roughly the same mass density as water—about 1 kg/L, which is

$$1 \text{ kg/L} \left(\frac{1 \text{ L}}{1 \times 10^{-3} \text{ m}^3} \right) = 1000 \text{ kg/m}^3.$$

The average human has a mass of about 70 kg, which corresponds to 70 L of water, and thus $V_{\text{human}} \approx (70 \text{ L})(1 \times 10^{-3} \text{ m}^3/1 \text{ L}) = 0.07 \text{ m}^3$, which is in the same ballpark as the estimate we got using the body-as-cylinder approach.

You may feel that there is too big a difference between 0.05 m^3 and 0.07 m^3. Indeed, if you were shopping for clothing, you'd want your clothing to fit your body better than that. However, here we are interested in only the order of magnitude. Either estimate is good enough for this purpose because for both the order of magnitude is the same: $0.05 \text{ m}^3 = 5 \times 10^{-2} \text{ m}^3$, which rounds to $10 \times 10^{-2} \text{ m}^3$, and so the order of magnitude is 10^{-1} m^3; $0.07 \text{ m}^3 = 7 \times 10^{-2} \text{ m}^3$, which also rounds to $10 \times 10^{-2} \text{ m}^3$, giving the same order of magnitude: 10^{-1} m^3.

Next we need to estimate the volume of a typical human cell. You may remember from biology class that the diameter of a typical cell is around $20 \ \mu\text{m} = 20 \times 10^{-6}$ m. Or, if you never learned cell sizes, you may recall that you can clearly see cells under a microscope and that a microscope can see objects as small as 10^{-6} m. To see the structure of a cell clearly under a microscope, the cell would need to be, say, at least 50 times the minimum size the microscope can handle, making our cell-diameter estimate 50×10^{-6} m. Although you may think there is a big difference between 20×10^{-6} m and 50×10^{-6} m, these two numbers are only a factor of 2.5 apart, which is much less than a factor of 10 ("one order of magnitude").

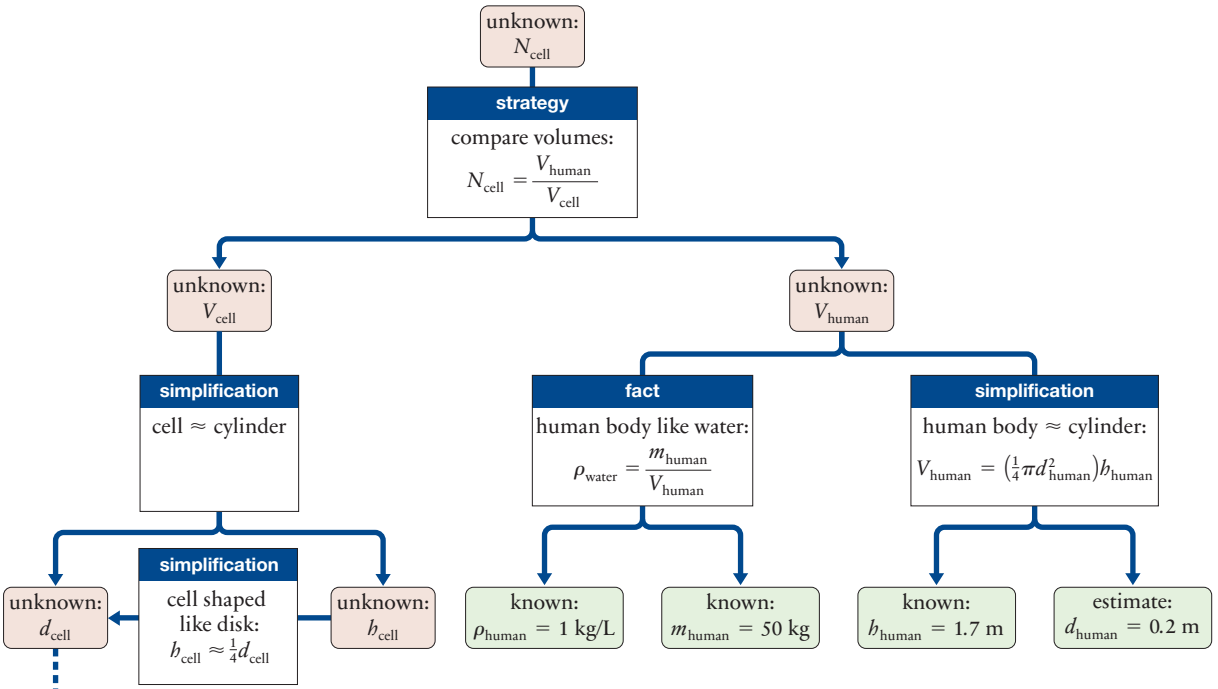
Cells viewed under a microscope tend to spread out on the glass and are thus less high than they are wide. Let's for simplicity assume they are disk-shaped and that their height is about one-quarter of their diameter. That means they have a diameter of 20×10^{-6} m and a height of 5×10^{-6} m, and so $V_{\text{cell}} = \left(\frac{1}{4}\pi d_{\text{cell}}^2\right) h_{\text{cell}} \approx 1.6 \times 10^{-15} \text{ m}^3$. The number of cells is thus $V_{\text{human}}/V_{\text{cell}} \approx (0.05 \text{ m}^3)/(1.6 \times 10^{-15} \text{ m}^3) \approx 3.1 \times 10^{13}$. Given the roughness of the estimates and assumptions, I give the final answer as an order of magnitude: 10^{14} (about 100 trillion cells).

I can be quite confident that the number of cells is somewhere between 10^{13} (10 trillion) and 10^{15} (1000 trillion), both substantially greater than the largest guess I offered earlier (100 billion = 10^{11}). The difference between that largest guess and the order-of-magnitude estimate is that I have no idea how much confidence to place in the guess, whereas I can feel reasonably certain about the result of my order-of-magnitude estimate.

You may think that this exercise is outrageous and that it is impossible to have faith in any order-of-magnitude value because it requires so many assumptions and estimates. However, the fact that we combine so many assumptions and estimates is precisely why the method works: We are unlikely to be either too high on every estimate or too low on every estimate. Instead, we unwittingly overestimate some values and underestimate others, and the over- and underestimates tend to cancel out. The result is that the final answer very likely is in the right ballpark. What is more important is that, in the process of obtaining an order-of-magnitude value, we develop insights and some feeling for the quantities involved.

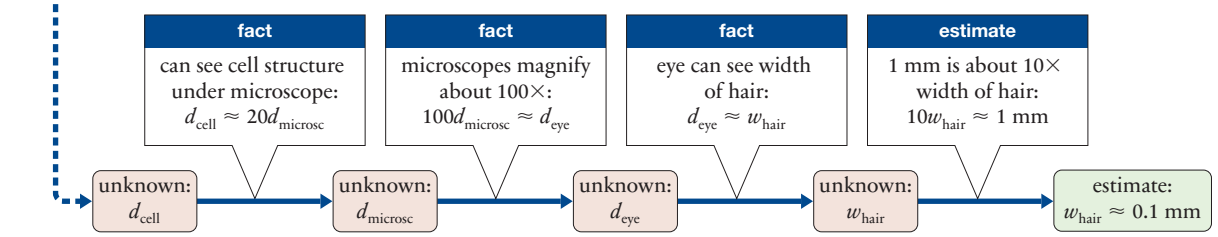
Figure 1.21 shows in graphical form the process by which we obtained our estimate of the number of cells N_{cell} in the human body. We got to our answer through a combination of *devising a strategy* (using a ratio of volumes to determine the number of cells), *simplifying* (treating the human body as a cylinder and the cell as a disk), *estimating* (the diameter of the human body),

and using snippets of *knowledge*. Figure 1.21 also shows why this approach can be intimidating at first: To determine a single target unknown, N_{cell}, we have to divide the problem into a larger number of questions, an approach that makes the number of unknowns increase initially! The point of this dividing, of course, is to arrive at values we know (or can guess).



The diagram in Figure 1.21*a* reduces the problem of obtaining N_{cell} to one of obtaining another value, d_{cell}. If you know the value of d_{cell} from your biology course, you are done. If you don't know the value, you can *translate* the problem into another one, as illustrated in Figure 1.21*b*. If you get stuck, guess upper and lower bounds for your unknowns, use the middle value to obtain an answer, and then reevaluate to see how your *guesstimate* affects the final answer.

Making order-of-magnitude estimates requires practice. As you go through the exercise more often, you'll gain confidence, and the process will come more naturally. An important point is not to worry too much about accuracy when working out orders of magnitude: A factor of 10 doesn't matter. You'll be surprised how far you can get with this technique, some resourcefulness, and commonly available knowledge.



1.15 To work an order-of-magnitude problem, you need the value of the mass density of water, but you don't know what that value is. Design either a translation strategy (Figure 1.21*b*) or a division strategy (Figure 1.21*a*) for making an order-of-magnitude estimate of this mass density.

Figure 1.21 The process by which we estimated the number of cells in the human body.

(*a*) A division strategy

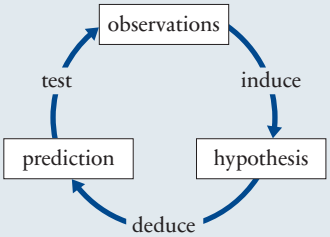
(*b*) A translation strategy

EXERCISE 1.11 Selling books

Consider writing a book for high-school graduates in the United States who are planning to take a year off—sometimes called a gap year—before enrolling in college. There are currently no similar books. Estimate how many such books might be purchased annually.

SOLUTION I can estimate the number of books sold by estimating the percentage of college-bound high-school graduates who take a gap year. I know two things: (1) Not all graduates do this, and (2) there is a rising interest in doing it. I estimate that 5% of high-school graduates take a gap year before going to college, but I still have to estimate the number of college-bound high-school students in the United States. I know that approximately 50% of high-school graduates go on to college, but how many high-school graduates are there each year?

If I assume every person in the country graduates from high school when she or he is 18, I've reduced this part of the problem to determining the number of 18-year-olds in the country. I know that the total population is 300 million and that the average life span is about 75 years. If I assume that age is uniformly distributed, then 1/75 of the U.S. population should be 18 years old at any given instant (this is an oversimplification but is good enough for an order-of-magnitude estimate). So the number of high-school graduates in a given year is $(1/75)(3 \times 10^8) = 4 \times 10^6$, and 5% of this is 2×10^5. Thus the number of students taking a gap year each year is approximately 200,000, which strikes me as a reasonable number. If 5% of these students buy the proposed book, about 10,000 copies will be purchased each year.



1.16 Make an order-of-magnitude estimate of the mass of Earth in kilograms.

Chapter Summary

The scientific method (Section 1.1)

Concepts The **scientific method** is an iterative process for going from observations to a hypothesis to an experimentally validated theory. If the predictions made by a hypothesis prove accurate after repeated experimental tests, the hypothesis is called a **theory** or a **law,** but it always remains subject to additional experimental testing.

Quantitative Tools

Symmetry (Section 1.2)

Concepts An object exhibits **symmetry** when certain operations can be performed on it without changing its appearance. Important examples are *translational symmetry* (movement from one location to another), *rotational symmetry* (rotation about a fixed axis), and *reflection symmetry* (reflection in a mirror). The concept of symmetry applies both to objects and to physical laws.

Some basic physical quantities and their units (Sections 1.3, 1.4, 1.6)

Concepts **Length** is a distance or extent in space. The SI (International System) base unit of length is the **meter** (m).

Time is a property that allows us to determine the sequence in which related events occur. The SI base unit of time is the **second** (s). The **principle of causality** says that whenever event A causes an event B, all observers see event A happen before event B.

Density is a measure of how much of some substance there is in a given volume.

Quantitative Tools If there are N objects in a volume V, then the *number density* n of these objects is

$$n \equiv \frac{N}{V}. \tag{1.3}$$

If an object of mass m occupies a volume V, then the *mass density* ρ of this object is

$$\rho \equiv \frac{m}{V}. \tag{1.4}$$

To convert one unit to an equivalent unit, multiply the quantity whose unit you want to convert by one or more appropriate *conversion factors*. Each conversion factor must equal one, and any combination of conversion factors used must cancel the original unit and replace it with the desired unit. For example, converting 2.0 hours to seconds, we have

$$2.0 \text{ h} \times \frac{60 \text{ min}}{1 \text{ h}} \times \frac{60 \text{ s}}{1 \text{ min}} = 7.2 \times 10^3 \text{ s}.$$

Representations (Section 1.5)

Concepts Physicists use many types of representations in making models and solving problems. Rough sketches and detailed diagrams are generally useful, and often crucial, to this process. Graphs are useful for visualizing relationships between physical quantities. Mathematical expressions represent models and problems concisely and permit the use of mathematical techniques.

Quantitative Tools As you construct a model, begin with a simple visual representation (example: represent a cow with a dot) and add details as needed to represent additional features that prove important.

Significant digits (Section 1.7)

Concepts The **significant digits** in a number are the digits that are reliably known.

Quantitative Tools If a number contains no zeros, then all the digits shown are significant: 345 has three significant digits; 6783 has four significant digits.

For numbers that contain zeros:

- Zeros between two nonzero digits are significant: 4.03 has three significant digits.
- Trailing digits to the right of the decimal point are significant: 4.9000 has five significant digits.
- Leading zeros before the first nonzero digit are not significant: 0.000175 has three significant digits.
- In this book, trailing zeros in numbers without a decimal point are significant: 8500 has four significant digits.

The number of significant digits in a product or quotient is the same as the number of significant digits in the input quantity that has the *fewest significant digits:* $0.10 \times 3.215 = 0.32$.

The number of decimal places in a sum or difference is the same as the number of decimal places in the input quantity that has the *fewest decimal places:* $3.1 + 0.32 = 3.4$.

Solving problems and developing a feel (Sections 1.8, 1.9)

Concepts Strategy for solving problems:

1. **Getting started.** Analyze and organize the information and determine what is being asked of you. A sketch or table is often helpful. Decide which physics concepts apply.
2. **Devise plan.** Determine the physical relationships and equations necessary to solve the problem. Then outline the steps you think will lead to the solution.
3. **Execute plan.** Carry out the calculations, and then check your work using the following points:
   - Vectors/scalars used correctly?
   - Every question answered?
   - No unknown quantities in answers?
   - Units correct?
   - Significant digits justified?
4. **Evaluate result.** Determine whether or not the answer is reasonable.

To develop a feel for the approximate size of a calculated quantity, make an **order-of-magnitude** estimate, which means a calculation rounded to the nearest power of ten.

Quantitative Tools Determining order of magnitude

Example 1:

4200 is 4.200×10^3.

Round the coefficient 4.200 to 10 (because it is greater than 3), so that 4.200×10^3 becomes $10 \times 10^3 = 1 \times 10^4$.

The order of magnitude is 10^4.

Example 2:

0.027 is 2.7×10^{-2}.

Round the coefficient 2.7 to 1 (because it is less than 3), so that 2.7×10^{-2} becomes 1×10^{-2}.

The order of magnitude is 10^{-2}.

Strategy to compute order-of-magnitude estimates:

- Simplify the problem.
- Break it into smaller parts that are easier to estimate.
- Build your estimate from quantities that you know or can easily obtain.

Questions and Problems

For instructor-assigned homework, go to Mastering Physics

Solving context-rich problems

The problems labeled CR are *context-rich* problems—problems that are more like those in the everyday world. These questions are typically embedded in a short narrative and often do not specify what variables you must calculate to answer the question. So, rather than asking What is the mass of . . . ? (telling you that you must calculate the mass of some object), a context-rich problem may ask Do you accept the bet? (leaving it to you to determine what to calculate). The problem typically contains extraneous information, and you may need to supply some missing information, either by estimation or by looking up values.

Like all problems, context-rich problems should be solved using the four-step procedure outlined in the Procedure box in this chapter. Because context-rich problem statements are never broken down into parts, the first two steps ("Getting started" and "Devise plan") are particularly important.

Context-rich problems will sharpen the skills you need to solve everyday problems, where you need to move toward a goal, but the path you must take is not immediately clear (if it were clear, there wouldn't be a problem). The information available to you may be a bit sketchy or contradictory, there may be more than one way to approach a situation, and some ways may be more fruitful than others, but that may not be clear at the outset. So consider context-rich problems as an opportunity to stretch your problem-solving abilities.

Dots indicate difficulty level of problems: • *= easy,* •• *=* ***intermediate,*** ••• *= hard;* CR *= context-rich problem.*

1.1 The scientific method

1. In a discussion of the technological capabilities of ancient civilizations, a friend offers this hypothesis: "Some ancient civilizations built sophisticated instruments based on a mysterious type of radiation, but all of them have been lost." Which part of his statement is most likely to keep the statement from satisfying the criteria for a scientific hypothesis? •
2. An advertisement for a food product states that it contains 50% less fat per serving than a competing product. What assumptions are you making if you accept the claim as valid? •
3. You are asked to predict the next item in the following sequence of integers: 1, 2, 3. If your prediction is 4, what assumptions did you make? ••
4. Checkpoint 1.1 states that two coins together have a value of 30 cents but one of them is not a nickel. If the checkpoint said instead that "neither coin is worth 5 cents," what hidden assumptions might prevent you from obtaining a solution? ••
5. In a 4-by-4 Sudoku puzzle with one 2-by-2 subsquare filled in as shown in Figure P1.5, how many ways are there to complete the puzzle? (In Sudoku, the digits 1, 2, 3, 4 must appear only once in each row and once in each column of the 4-by-4 square and only once in each subsquare.) •••

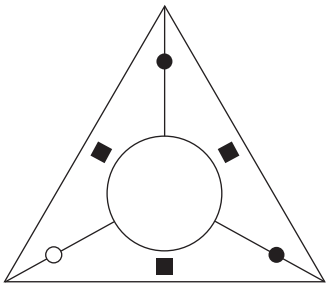


Figure P1.5

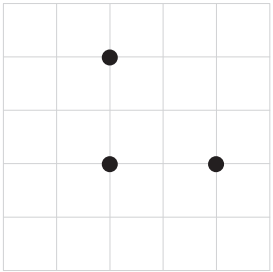
4	3		
1	2		

1.2 Symmetry



6. How many axes of reflection symmetry does the triangle in Figure P1.6 have? Restrict your answer to axes that lie in the plane of the triangle. •

Figure P1.6

7. How many axes of rotational symmetry does a right circular cone have? •
8. Three identical coins are positioned on a grid as shown in Figure P1.8. Where would you place a fourth coin to form a coin arrangement that has both reflection symmetry and a 90° rotational symmetry? •

Figure P1.8

9. Describe the reflection symmetry of each of the letters in the word below: ••

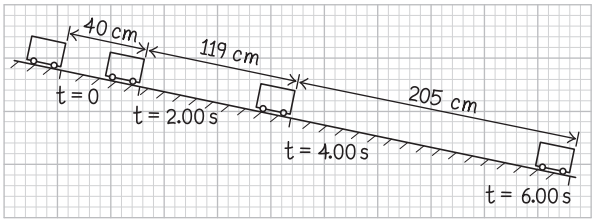
T A B L E S

10. Which types of geometrical symmetry mentioned in this chapter does a sphere have? ••
11. How many axes of reflection symmetry does a cube have? How many axes of rotational symmetry? ••
12. Suppose you have a disk of cardboard with two perpendicular diameters dividing the disk into four quadrants. The first and third quadrants taken clockwise from the topmost point of the disk are red, whereas the other two are white. How many axes of reflection does the disk have? Restrict your answer to axes in the plane of the disk. Does the disk have rotational symmetry about any axis perpendicular to the plane of the disk? ••
13. A cube is placed on a table with a green side facing up. You know that the side facing down is also green but has a red dot in the middle of the green face. From where you are sitting, you can see that two adjacent vertical sides are one red and the other blue. What is the maximum number of axes of reflection symmetry possible? •••

1.3 Matter and the universe

14. Traveling at 299,792,458 m/s, how far does light travel in 78 years? •
15. Light takes approximately 500 seconds to travel from the Sun to the Earth. (*a*) What is this distance in kilometers? (*b*) How many Suns could fit side by side in this distance? Take the radius of the Sun to be 696,000 km. •
16. Figure 1.9 tells us that a human contains 10^{29} atoms and a blue whale contains 10^{32} atoms. Use these values to determine the ratio of the length of a blue whale to the height of a human. ••
17. A gastrotrich is a small aquatic organism with a life span of about 3 days, and a giant tortoise has an average life span of 100 years. Make an order-of-magnitude estimate of the number of gastrotrich lifetimes that are equal to one tortoise lifetime. In your calculation, use an order-of-magnitude value for the number of days in 1 year. ••
18. You measure the diameter of a drop of water to be 3 mm. Make an order-of-magnitude estimate of how many such drops are contained in all the water in your body. ••
19. If you could stack copies of your physics textbook until they reached the Moon, what is the order of magnitude of the number of books you would need? ••
20. How many water molecules are there in an Olympic swimming pool that is 50 m long, 25 m wide and 3.0 m deep? ••
21. Cube 1 has side ℓ_1 and volume V_1. Cube 2 has side $\ell_2 = 2\ell_1$. (*a*) When making order-of-magnitude estimates, by how many orders of magnitude is the volume of the second cube greater than the volume of the first cube? (*b*) Does the answer depend on the numerical value of ℓ_1? ••
22. Earth requires approximately 365 days to orbit the Sun along a path that can be approximated by a circle with a radius of 1.50×10^8 km. Make an order-of-magnitude estimate of the length of time it would take light to move once around this orbit. ••
23. While admiring a tree, you notice that the leaves form a more or less continuous spherical shell, with relatively few leaves growing in the shell interior. You estimate that the diameter of this shell is about 30 m. Each leaf is about 5 in. long and 3 in. wide. Make an order-of-magnitude estimate of the number of leaves on this tree. •••

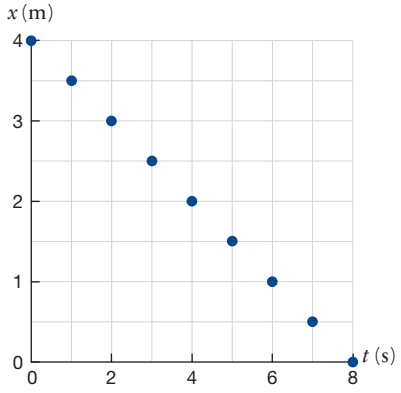
1.4 Time and change



24. A human heart beats 72 times every minute. How many times, on average, does a heart beat during a healthy 70-year lifespan? (Ignore the fact that the rate at which the heart beats can vary widely with the level of physical activity.) •
25. You hear a peal of thunder and go to the window. You then see a flash of lightning. Is it reasonable to assume that the thunder caused the lightning? •
26. A second is defined as the duration of 9.19×10^9 periods of the radiation emitted by a cesium atom. What is the duration in seconds of a single period for this atom? •
27. While watching a railroad crossing, you observe that a crossing barrier is lowered about 30 s before a train passes. This happens every time for a long while, until suddenly after many times the barrier is not lowered but a train passes anyway! Discuss the causal relationship between the passing of a train and the lowering of the barrier. Does the single unusual occurrence make a difference to your answer? ••
28. Assume the radiation from the cesium atom mentioned in Problem 26 moves at the speed of light. How many meters does the radiation travel in the length of time corresponding to the period calculated in Problem 26? ••

1.5 Representations

29. Translate this statement into a mathematical expression, using any symbols you wish, but include a "key" to the meaning of each symbol: The wavelength of any electromagnetic radiation traveling in a vacuum is equal to the speed of light divided by the frequency of that radiation. •
30. A planar shape is formed by joining the ends of four straight-line segments, two with length ℓ and two with length 2ℓ. No loose ends are allowed, but crossings are allowed, and only two segment ends may join at any single point. The ends of identical-length segments cannot join each other. What shapes are possible? ••
31. Four straight-line segments of length ℓ lie in a plane and do not cross. One end of segment 1 is connected to one end of segment 2 such that they form a 30° interior angle. The other end of segment 2 is connected to one end of segment 3, also forming a 30° interior angle. Finally, the other end of segment 3 is connected to one end of segment 4, forming another 30° interior angle. What is the distance between the unconnected ends of segments 1 and 4? ••
32. You are arranging family members for a photograph, and you want them to stand in order of increasing height. Your uncle is half a foot shorter than your aunt, who is taller than your cousin. Your grandmother is 2 in. shorter than your grandfather. Your brother is 1 in. taller than your aunt and 3 in. taller than your cousin. Your grandfather is 1 cm taller than your aunt. List the relatives in order of increasing height. ••
33. The Jupiter–Sun distance is 778 million kilometers, and the Earth–Sun distance is 150 million kilometers. Suppose an imaginary line from Jupiter to the Sun forms a right angle with an imaginary line from Earth to the Sun. How long would it take light to travel from the Sun to a spaceship halfway along the straight-line path between Jupiter and Earth? ••



34. During a physics lab, you and your partner keep track of the position of a small cart while it is moving along a slope. The lab instructions ask you to prepare (*a*) a pictorial representation of the experiment, (*b*) a table recording the position of the cart measured every 2.00 seconds from its initial position, and (*c*) a graph that shows the position of the cart on the vertical axis and time on the horizontal axis. You produce the sketch shown in Figure P1.34. What should your table and your graph look like? ●●

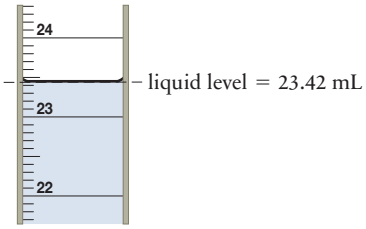
Figure P1.34

35. The graph in Figure P1.35 shows a relationship between two quantities: position x, measured in meters, and time t, measured in seconds. Describe the relationship using (*a*) a verbal expression and (*b*) a mathematical expression. ●●●

Figure P1.35

36. You have four equilateral triangles, two red and two blue. You want to arrange them so that each blue triangle shares a side with the other blue triangle and with both red triangles, and each red triangle shares a side with the other red triangle and with both blue triangles. How can this be done? ●●●

1.6 Physical quantities and units



37. The world record for the 100 m dash was set at 9.58 seconds a few years ago. What is this speed in kilometers per hour? In miles per hour? ●
38. A weather balloon can rise to an altitude of 80,000 ft above sea level. What is this distance in miles? In meters? ●
39. A metal block of uniform mass density is cut into two pieces. How does the density of each piece compare with the density of the original block (*a*) if each piece has half the volume of the original block and (*b*) if one piece has one-third of the original volume? ●
40. Take the speed of sound in air at standard temperature and pressure to be 343 *m/s*. Convert this speed to kilometers per hour, inches per nanoseconds, and miles per second. ●●
41. Suppose you measure the mass and volume of two solid stones. Stone 1 has a mass of 2.90×10^{-2} kg and a volume of 10.0 cm^3. Stone 2 has a mass of 2.50×10^{-2} kg and a volume of 7.50 cm^3. Is it likely that the stones are made from the same material? ●●
42. The Dubai World Cup horserace is 2000 meters long. Express this distance in miles. ●●
43. You measure a quantity T that can be represented as $= 2\pi\sqrt{\frac{l}{g}}$. If T and l have the units of seconds and meters, respectively, then what should the units of g be for the expression to be correct? ●●
44. Both *mass* and *volume* can be used to describe the amount of matter present in an object. What physical quantity relates these two concepts? ●●
45. The average radius of Earth is 6371 km. Give order-of-magnitude estimates of what the mass of Earth would be if the planet has the mass density of (*a*) air (≈ 1.2 kg/m^3), (*b*) 5515 kg/m^3, and (*c*) an atomic nucleus ($\approx 10^{18}$ kg/m^3). ●●
46. Suppose $x = ay^{3/2}$, where $a = 7.81\ \mu g/Tm$. Determine the value of y when $x = 61.7\ (Eg \cdot fm^2)/(ms^3)$. Express the result in scientific notation and simplify the units. (Hint: Refer to Table 1.3, and note that SI prefixes are never used to multiply powers of units. For example, the abbreviation cm^2 means $(10^{-2}\ m)^2$, not $10^{-2}\ m^2$, and ns^{-1} is 1/ns or $10^9\ s^{-1}$, not $10^{-9}\ s^{-1}$. Also note that m can stand for meter or for milli, depending on the context.) ●●●

1.7 Significant digits

47. (*a*) What is the speed of light in vacuum expressed to three significant digits? (*b*) What is the square of the speed of light in vacuum expressed to three significant digits? (*c*) Is the numerical value in part *b* the square of the numerical value in part *a*? Why or why not? ●
48. Express the distance of the Dubai World Cup horserace in kilometers to the same number of significant digits needed to answer problem 42. ●
49. You have 2.28 kg of rice and wish to divide it evenly among five people. If you calculate how much rice each person receives, how many significant digits does your answer have? ●
50. You are recording your car's petrol consumption. Your odometer measures to the tenth of a kilometer. The gas-station pump displays liters of gasoline dispensed to the thousandth of a liter. Given these levels of precision, is there any difference in the precision of your calculation when you drive 60.0 kilometers or 600.0 kilometers? ●●
51. The odometer on your car says 35,987.1 km. To the correct number of significant digits, what should the odometer read after you drive another 47.00 m? ●●

52. A certain brand of soft drink contains 34 mg of caffeine per 355-mL serving. If one mole of caffeine has a mass of 194.19 g and you drink an average of two servings of this drink a day, how many caffeine molecules do you ingest in one year? ••
53. You work in a hospital and are preparing a saline solution for a patient. This solution must have a concentration of 0.15 mol of NaCl (mass of one mole, 58.44 gram) per liter of solution. You have lots of volume-measuring devices, but the only mass-measuring tool you have is a balance that measures mass to the nearest 0.1 g. What is the minimum amount of solution you should mix? ••
54. You find a container of an unknown clear liquid. You are interested in its contents, but you have no chemical analysis devices at hand. You do have a good electronic scale, so you measure out 25.403 g of the liquid and then pour this liquid into a graduated cylinder, with the level indicated in Figure P1.54. What is the mass density of this liquid? ••

Figure P1.54

55. Suppose that, in a laboratory exercise, you add 0.335 g of liquid to a 145.67-g ceramic bowl. After you heat the liquid for 25.01 s, you measure the mass of the bowl and liquid together to be 145.82 g. What was the average mass of liquid that evaporated each second? •••

1.8 Solving problems

56. A test question gives the mass density of seawater and asks what volume is occupied by 1.0×10^3 kg of seawater. Someone answers 0.9843 m. Without knowing the mass density value given, explain what is wrong with this answer. •
57. You measure a watch's hour and minute hands to be 8.0 mm and 11.3 mm long, respectively. In one day, by how much does the distance traveled by the tip of the minute hand exceed the distance traveled by the tip of the hour hand? ••
58. An Olympic running track consists of two straight sections, each 84.39 m long, and two semicircular ends, each with a radius of 36.80 m as measured from the inside lane (lane 1). There are eight lanes, each 1.22 m wide. If runners did not start staggered (so that each runner covers the same distance), by how much would the distance traveled by a runner in lane 8 exceed the distance traveled by a runner in lane 1 over one lap? ••
59. You have three coins that are identical in appearance. One is counterfeit, and its mass is different from the mass of the two legitimate coins. You also have an equal-arm balance (a device that compares the masses of two objects and "balances" if they are equal). Describe how you can determine which is the counterfeit coin and whether it is heavier or lighter than the legitimate coins by making only two measurements with the balance. ••
60. A certain type of rice has an average grain length and diameter of 6 mm and 2 mm, respectively. One cup of this rice, after being cooked, contains about 785 food calories. (*a*) How many grains are there in 1 cup of rice? (*b*) How many calories are there in one grain? (*c*) How many cups of uncooked rice are needed to provide 2000 food calories to each of four adults? •••

1.9 Developing a feel

61. What is the order of magnitude of the number of moles of matter in the observable universe? •
62. You add about 10^2 raisins to a loaf of bread you are baking. When fully baked, the loaf is hemispherical with a radius of about 8 in. What is the order of magnitude of the average distance between neighboring raisins? •
63. A tree cut down for lumber has a diameter of 0.80 m over its length of 32 m. About how many 6-ft-long, 2-in. by 2-in. boards can be made from this tree? •
64. Estimate the order of magnitude of the number of times the letter d occurs in this text. ••
65. Estimate the combined length of all the hairs on the head of a person who has a a full head of shoulder-length hair. ••
66. An urban legend making the rounds in quantitative reasoning classes is that a student paid for four years at a private university in the United States exclusively with redeemed deposits on soda cans collected from people's trash. Estimate whether this is possible. ••
67. Computer hard drives have increased dramatically in capacity since their introduction in the 1950s. The first commercial hard drive had a capacity of about 3.8 MB stored on 50 circular platters, each 610 mm in diameter. In the early part of this century, hard drives approached 1.0 TB of storage using just five platters, each with a diameter of about 90 mm. By what order-of-magnitude factor does the storage capacity per unit area of a 21st-century drive exceed that of an original drive? ••

Additional Problems

68. At present, the tallest man-made structure is the Burj Khalifa in Dubai. Express the height of this building in nanometers. How many atoms would need to be stacked to get to the same height? •
69. A 200-sheet stack of loose-leaf paper is 2.75 in. thick. What is the thickness in millimeters of one sheet? •
70. A water tank is filled to its 10×10^4-L capacity. (*a*) What is the tank's volume in cubic meters? (*b*) What is the mass of the water in micrograms? (*c*) If your household consumed ten 500-cc bottles of water a day, how long would the water in the tank last? ••
71. You are working on an exhibit of the atom at a science museum. You want the exhibit to have a model of the atom in which the nucleus is big enough for visitors to see, about 500 mm in diameter. The model needs to fit inside a square room with walls about 25 m long. Will it fit if you make the nucleus this size? ••

72. Recent experimental values for the universal gravitational constant, the mass and mean radius of Earth, and the standard gravitational acceleration are

$$G = 6.6738 \times 10^{-11}\ \text{m}^3 \cdot \text{kg}^{-1} \cdot \text{s}^{-2}$$
$$M_E = 5.9736 \times 10^{24}\ \text{kg}$$
$$R_E = 6.378\,140 \times 10^{6}\ \text{m}$$
$$g = 9.806\,65\ \text{m} \cdot \text{s}^{-2}$$

Assuming a spherical Earth, these quantities are related by the expression $gR_E^2 = GM_E$. (*a*) To how many significant digits is this relation satisfied using the recent data? (*b*) Can you round off all the data to the same number of significant digits before multiplying and still satisfy this relation to that number of significant digits? If so, what numbers of significant digits work? ●●

73. You are in charge of safety at a local park. A tire swing hangs from a tree branch by a 5-m rope, and the bottom of the tire is 1 m from the ground directly beneath it. The land is sloped at a 12° angle toward a pond. From experience, you know that even an energetic user will be unlikely to cause the swing to make a maximum angle exceeding 30° with respect to the vertical. You are certain that parents will want reassurance about the safety of the tire swing. ●●● CR

74. While working for a space agency, you are tasked with ensuring that the oxygen needs of human beings on long voyages in outer space are met. Your boss hands you a data table and suggests that you consider the amount of oxygen a person might need in 1 year as well as the storage requirements for this oxygen at room temperature and atmospheric pressure. ●●● CR

Volume of one breath	4.5 L
Oxygen content of air, by volume	20.95%
Percent oxygen absorbed per breath	25%
Average breathing rate	15 breaths/min
Mass density of air at room temperature and atmospheric pressure	1.0 kg/m^3

75. Neutron stars can have a mass on the order of 10^{30} kg, but they have relatively small radii, on the order of tens of kilometers. (*a*) What order of magnitude is the mass density of a neutron star? (*b*) How many orders of magnitude larger is this than the mass density of Earth? Of water? (*c*) If water had the mass density of a neutron star, what order of magnitude of mass would be contained in the soda in a full 2-L bottle? ●●●

CONCEPTS

QUANTITATIVE TOOLS

The branch of physics that deals with the quantitative representation of motion is called *kinematics*. Kinematics does not consider the causes and effects of motion; its goal is simply to provide a mathematical description of motion. In this chapter, we follow a kinematics approach; that is, we represent motion on a graph and quantify that motion without worrying about what causes it. In Chapter 8 we shall begin to look at the causes of motion, but for now all we care about is the motion while it is happening.

By describing the motion represented in a video, we begin to develop the most basic skill in physics: making simplified representations of real-world situations. You'll see how to use tables, graphs, and mathematical functions to represent quantitative data on motion. Finally, you'll learn the distinction between the terms *position* and *displacement* as well as the distinction between *speed* and *velocity*.

2.1 From reality to model

The opening picture of this chapter shows the *Shinkansen*—the Japanese bullet train—speeding by Mount Fuji. Although the image conveys the idea of motion, it does not contain any quantitative representation of that motion. If I were to ask, "How fast is the train moving?" you wouldn't be able to answer if all you had to go on was this photograph. In order to answer my question, you need a more quantitative representation of the motion.

To analyze the motion of an object, we need to keep track of the object's position at different instants. If the position changes as time passes, the object is in motion. If the position is not changing, the object is said to be **at rest.** As a first step in measuring position, let's analyze the video clip reproduced in **Figure 2.1**, a record of me walking (and you thought physics was going to be dull!). As you can see from the clip, I first walked forward a certain distance, stood still for a short while, and then walked backward.

The imaginary straight line on the ground along which I took my steps is our *reference axis*. My position is determined by my location along this axis relative to some arbitrarily chosen reference point called the *origin*. Giving my position at different instants in time determines my motion in much the same way the video does. Choosing the left edge of the frame as the origin, we can say that in frame 1 the center of my body (in reality, the *image* of my body) is 2.5 mm from that point; a few frames later it is 8.5 mm from the edge (frame 5); another few frames and it is 12.0 mm from the edge (frame 8). In other words, we can describe my motion by specifying my position for every frame, which is what **Table 2.1** does.

The same information is shown graphically in **Figure 2.2**, where my position relative to the left edge is plotted along the vertical axis and the horizontal axis represents the frame number. The formal way of describing this

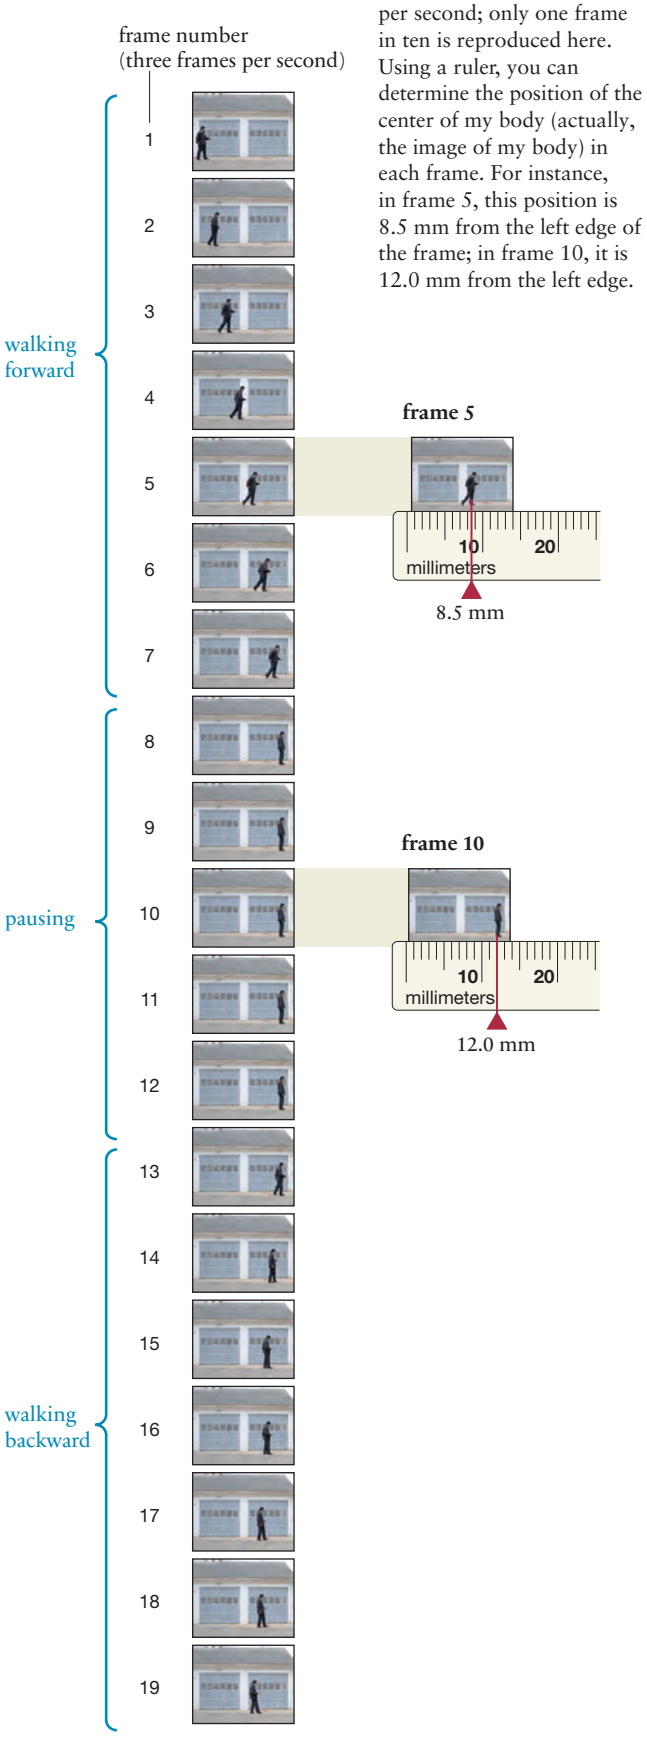

Figure 2.1 Video clip showing me walking to the right, pausing, then walking back to the left. The camera recorded this event at 30 frames per second; only one frame in ten is reproduced here. Using a ruler, you can determine the position of the center of my body (actually, the image of my body) in each frame. For instance, in frame 5, this position is 8.5 mm from the left edge of the frame; in frame 10, it is 12.0 mm from the left edge.

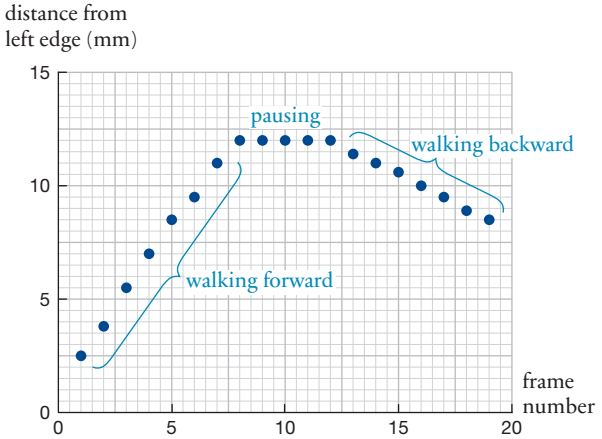


CONCEPTS

Table 2.1 Position versus frame number from the video sequence in Figure 2.1

Frame number	Distance from left edge (mm)	Position x (m)	Time t (s)
1	2.5	+1.0	0
2	3.8	+1.5	0.33
3	5.5	+2.2	0.67
4	7.0	+2.8	1.00
5	8.5	+3.4	1.33
6	9.5	+3.8	1.67
7	11.0	+4.4	2.00
8	12.0	+4.8	2.33
9	12.0	+4.8	2.67
10	12.0	+4.8	3.00
11	12.0	+4.8	3.33
12	12.0	+4.8	3.67
13	11.4	+4.6	4.00
14	11.0	+4.4	4.33
15	10.6	+4.2	4.67
16	10.0	+4.0	5.00
17	9.5	+3.8	5.33
18	8.9	+3.6	5.67
19	8.5	+3.4	6.00

graph is to say that it shows my position (information on the vertical axis) *as a function of* the frame number (information on the horizontal axis). The coordinates of the center of each circle correspond to the values listed in the first two columns in Table 2.1. The size of the circle is representative of the accuracy of the measurements. The upward trend of data points between frames 1 and 8 indicates that my distance from the left edge increases with increasing frame number and represents my motion walking from left to right. Then, representing the time interval when I stood still, the data points stay flat from frame 8 to 12. Finally, from frame 12 onward, the data points show a downward trend representing my motion back to the left.

Figure 2.2 My distance from the left edge of each frame in Figure 2.1 versus frame number. We see that I start, in frame 1, 2.5 mm from the left edge of the frame, walk forward to 12.0 mm from the left edge at frame 8, stay there for five frames, then walk backward to 8.5 mm from the left edge.

2.1 (*a*) Using a metric ruler, measure the position of the center of my body from the left edge in each frame of Figure 2.1. Compare your list of values with the positions given in Table 2.1. (*b*) Plot the positions you measured as a function of frame number—no need for graph paper, just draw your axes and plot your data by eye.

Taking information from the real world and creating a simplified abstract representation of it—making a model of a real-world happening—is one of the most important skills in physics. You'll be making such models hundreds of times throughout this course, some graphical like Figure 2.2, some in the form of tables as Table 2.1, some in the form of mathematical expressions.

2.2 (*a*) In Figure 2.2 the data points for frames 8–12 are all at position 12.0 mm. Explain what this alignment of data points means in terms of what is happening in the real world. (*b*) The data points for frames 7 and 14 are aligned horizontally. What does this alignment imply about the real-world motion? (*c*) What would it mean if two data points were aligned vertically? Could this happen?

2.2 Position and displacement

Figure 2.2 is of limited value as a model of a real-world happening. It tells us only that, in 19 frames of a certain video displayed on a screen, my image moved from a position 2.5 mm from the left edge of the frame to a position 8.5 mm from the edge. It would be more useful to have this information in terms of real-world distances and time intervals. To know what distance I traveled and how long the trip took, I should have put markers on the ground at known intervals and a clock in the camera's field of view. Even though I did not do this, we can still determine position and time by *calibrating* the graph, as you can see in the next checkpoint.

2.3 (*a*) Take a reasonable guess at my height and calculate what real-world distance 1 mm in Figure 2.1 corresponds to. (*b*) Using this result, calculate the distance I walked between frames 1 and 10.

This checkpoint gives a procedure for calibrating the vertical axis in Figure 2.2 without taking any new pictures. Using 1.8 m as my height, I obtained the position values listed in the third column of Table 2.1. For motion in one dimension, position can be represented by the x coordinate along a reference axis (also called the x axis),

CONCEPTS

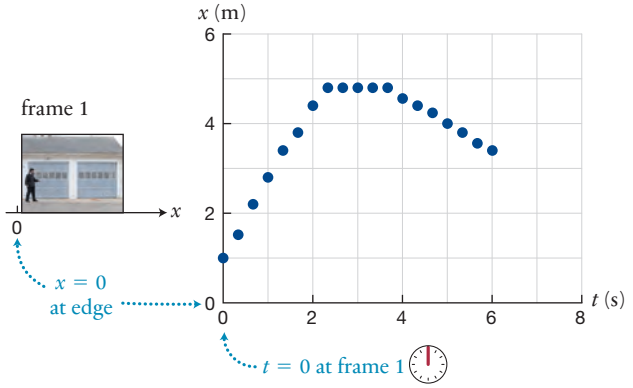
and this coordinate is denoted by the symbol x. Because the x coordinate can be positive or negative, we always explicitly denote its algebraic sign. In frame 4, for example, my position is given by $x = +2.8$ m. Note that by following this procedure, x values increase to the right.

We can do something similar for time. The camera takes 30 frames per second, and so the time interval between successive frames on the original video is $1/30$ s $= 0.033$ s. If we imagine having started a stopwatch at the first frame, that stopwatch would read 0.033 s at the second frame, 0.067 s at the third, 0.100 s at the fourth, and so on. Because only every tenth frame is shown in Figure 2.1, we must multiply these readings by 10. All these clock readings are listed in the fourth column in Table 2.1. Clock readings are represented by the symbol t; each value of t represents an instant in time. In everyday language *instant* can mean different things. For example, when you say, "I'll be back in an instant," the word *instant* refers to a short time interval. In physics, however, an instant has no duration at all; it represents a single value in time.

Figure 2.3 shows the resulting calibrated data in graphical form, with the position given by x on the vertical axis and time t on the horizontal axis. We refer to such a graph as a *position-versus-time graph*.

To obtain the data shown in Figures 2.2 and 2.3, we arbitrarily chose an origin. An origin is always needed in order to specify a position: The statement "the ball's position is $x = +3.2$ m" makes no sense unless we know from where to start measuring these 3.2 meters. The choice of origin is arbitrary. In analyzing Figure 2.1, for instance, I arbitrarily chose the left edge of the frame as the origin. To show that the choice of origin is arbitrary, suppose we replot our data, but now take my position in frame 1 to correspond to $x = 0$ and the clock reading at the first frame to be $t = 0.33$ s. Doing so produces the graph shown in **Figure 2.4**. Compare this graph with Figure 2.3 and you see that the change in origin and in the instant at which $t = 0$ changes the x and t values of each data point. However, as the next checkpoint shows, changing the origin and the instant at which $t = 0$ does not affect the relative positions of the data points.

Figure 2.3 Position-versus-time graph obtained by calibrating the data points in Figure 2.2. The vertical axis now represents my position, measured in meters, relative to a point on the left edge of the frame. The x and t values are listed also in Table 2.1.



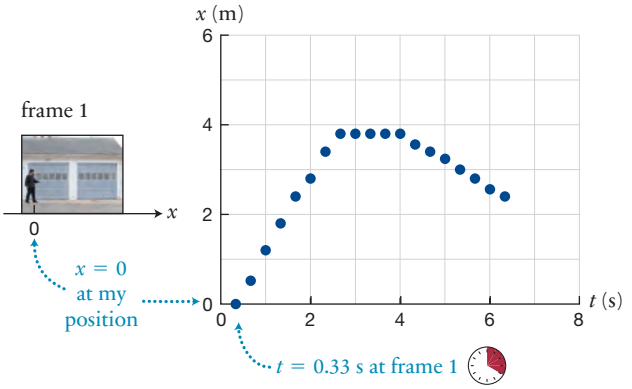


Figure 2.4 Position-versus-time graph for the data plotted in Figure 2.3, but with a different choice of origin.

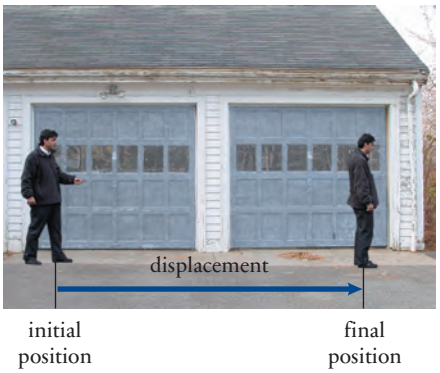


2.4 (*a*) What are the final position values in Figures 2.3 and 2.4? (*b*) What values are obtained by subtracting the initial position value from the final position value in each figure?

We can represent the motion of an object that moves from one position to another by an arrow that points from the initial position to the final position (**Figure 2.5**). This arrow represents a physical quantity called the **displacement** of the object. The displacement does not depend in any way on the choice of reference axis or origin; you don't need any axis to draw the arrow in Figure 2.5. Numerically, we can represent the displacement by subtracting the initial x coordinate from the final x coordinate. The resulting value is called the *x component of the displacement:*

The x component of an object's displacement is the change in its x coordinate. The value of the x component of the displacement is obtained by subtracting the initial x coordinate from the final x coordinate and is independent of the choice of origin.

Figure 2.5 The arrow pointing from my initial position to my final position represents my displacement.

CONCEPTS

The term *x component* serves to remind us that this quantity is measured along some specific x axis. In the second part of this chapter you will see how to specify a displacement like the one in Figure 2.5 by choosing an x axis and determining the x component of the displacement. Later on, in Chapter 10, when we discuss motion that is not along a straight line, we shall need more than one axis and a correspondingly larger number of components to specify displacements.

Note that the x component of the displacement can be either positive or negative: It is positive for displacements in the direction of increasing x and negative for displacements in the direction of decreasing x. To remind ourselves of this fact, we shall always explicitly denote the algebraic sign of the x component of the displacement. The x component of the displacement between my initial and final positions in Figure 2.3, for example, is +2.4 m, indicating that I end up 2.4 m to the right of my starting position.

Returning to Checkpoint 2.4, we see that because every data point in Figure 2.4 is shifted down and to the right by exactly the same amount, the value obtained by subtracting the initial x coordinate from the final x coordinate is not affected by the change in origin. If it puzzles you that the x component of the displacement is independent of the choice of origin, consider the following: Suppose you tell a friend, "See you at the bakery in thirty minutes." Even if your watch says 3:30 at that instant and your friend's watch says 2:30, you will both arrive at the bakery at the same time: 30 minutes after you made the date. Your reference point is the clock reading 3:30 and your friend's reference point is the clock reading 2:30, but both of you add the same value—30 minutes—to your reference point. Just like the x component of the displacement (a *change in* the x coordinate), a time interval (a *change in* the clock reading) does not depend on the choice of reference point.

2.5 Suppose you walk in a straight line from a point P to a point Q, 2 m away from P, and then walk back along the same line to P. (*a*) What is the x component of your displacement for the round trip? (*b*) What distance did you travel during the round trip? (*c*) Is *distance traveled* the same thing as the *x component of the displacement*?

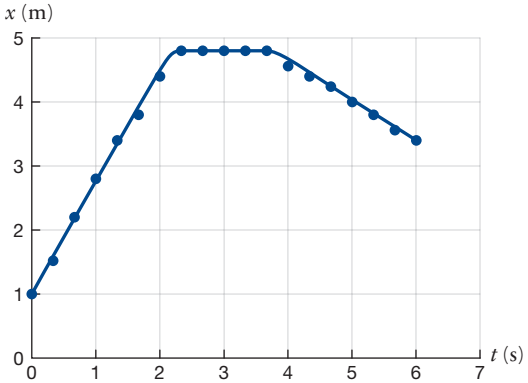
As this checkpoint shows, it is important to distinguish between the x component of the displacement and the *distance traveled*.

The distance traveled is the distance covered by a moving object along the path of its motion.

In contrast to the x component of the displacement, which can be either positive or negative, the distance traveled is always positive. Note also that, for an object that turns around, as in Checkpoint 2.5, the distance traveled is greater than the distance between the endpoints. Only when the motion is always in the same direction is the distance traveled equal to the distance between the endpoints.

2.3 Representing motion

The graphs of Figures 2.3 and 2.4 specify position only at the specific instants represented by the frames in Figure 2.1. What about the positions at intermediate instants? To answer this question, we would need to look at all the frames taken between those shown in Figure 2.1. Doing so would give us ten times as many data points because the camera took ten times the number of frames shown in the figure. If we wanted information more detailed than that, we would need a camera that takes more than 30 frames per second.



As we repeat our measurements over smaller and smaller time intervals, the spacing between data points becomes increasingly smaller, eventually yielding what looks like a continuous curve instead of discrete points. If we assume the motion proceeds smoothly from frame to frame, we can obtain the same result by *interpolating* the data points in Figure 2.3—in other words, by drawing a smooth curve through the points, as in **Figure 2.6**.

2.6 (*a*) From Figure 2.6, how many seconds did it take me to go from $x = +1.0$ m to $x = +4.0$ m? (*b*) From $x = +2.0$ m to $x = +3.0$ m? (*c*) At what instant did I reach $x = +2.5$ m? (*d*) For how long was I at $x = +2.5$ m?

Figure 2.7 shows how the position-versus-time graph of Figure 2.6 relates to Figure 2.1. Figure 2.6 is a further simplification of our representation of the motion in the video clip. In reality, the motion may have been less smooth than the graph suggests. However, the video clip and Figure 2.6 both tell the same story: I moved forward about 3.8 m in 2.3 s, stood still for 1.3 s, and then moved 1.4 m backward in 2.3 s. Even though it gives less detail than the video clip, the simple curve in Figure 2.6 entirely describes the motion.

Figure 2.6 By interpolating the data points in Figure 2.3, we obtain a smooth curve representing my motion.

CONCEPTS

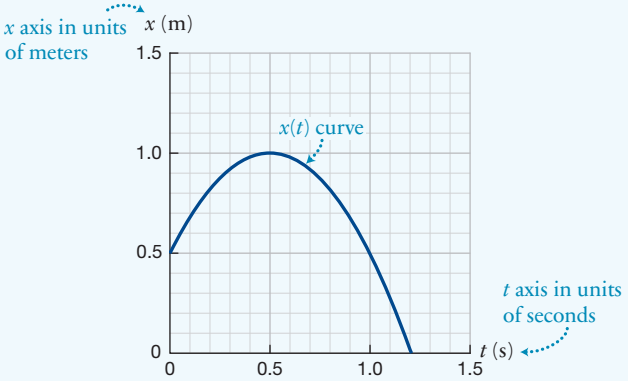


Figure 2.7 If you connect the images in sequential frames by a line, you obtain a curve representing the motion. Turn the page sideways and compare the curve through the images with the curve in Figure 2.6.

EXAMPLE 2.1 Graphical representation

The curve in **Figure 2.8** is a graphical representation of the motion of a certain object. (*a*) What was the x coordinate of the object at $t = 0.50$ s? (*b*) At what instant(s) did the object reach $x = +0.80$ m? (*c*) What distance did the object travel between $t = 0.80$ s and $t = 1.2$ s? (*d*) How long did it take for the object to move from $x = +1.0$ m to $x = 0$?

Figure 2.8 A position-versus-time graph representing the motion of an object. The curve, which shows the position of the object at any instant between $t = 0$ and $t = 1.2$ s, can be represented by a mathematical function $x(t)$ (Examples 2.1 and 2.2).

❶ **GETTING STARTED** This problem requires me to use Figure 2.8 to answer questions about the motion of the object. The problem boils down to reading off values from the graph.

❷ **DEVISE PLAN** To find the object's position x at a given instant t, I draw (or imagine drawing) a vertical line at the value on the t axis corresponding to the given instant in time and read off the value of x at which that line intercepts the curve in the graph. Likewise, to find the instant t at which the object is at a given position x, I draw a horizontal line at the given value of x and read off the value of t at which that horizontal line intercepts the curve.

❸ **EXECUTE PLAN** (*a*) A vertical line drawn at $t = 0.50$ s in Figure 2.8 intercepts the curve at $x = +1.0$ m. ✔

(*b*) A horizontal line at $x = +0.80$ m intercepts the curve at $t = 0.20$ s and at $t = 0.80$ s. ✔

(*c*) At $t = 0.80$ s the object was at $x = +0.80$ m, and at $t = 1.2$ s it was at $x = 0$. The distance traveled was thus 0.80 m. ✔

(*d*) The object was at $x = +1.0$ m at $t = 0.50$ s and at $x = 0$ at $t = 1.2$ s. Thus it took the object 1.2 s − 0.50 s = 0.7 s to move between these points. ✔

✔ The checkmarks show that I carried out the following checks: Vectors and scalars used appropriately; Everything answered; No unknowns left; Units correct; Significant digits justified.

❹ **EVALUATE RESULT** That I obtain two instants in part *b* is OK because the object can return to a certain position. The answers to parts *c* and *d* (0.80 m and 0.7 s) are within the range of the curve (1.0 m and 1.2 s), so my answers are not unreasonable.

CONCEPTS

A curve in a position-versus-time graph like the one shown in Figures 2.6 and 2.8 is called an $x(t)$ *curve* because it can be represented by a mathematical function $x(t)$. The curve and the function specify where the object is at any given instant. Note that $x(t)$ is a single symbol that means "x at instant t"; it is not the product of x and t and should not be confused with the label "x (m)" on the x axis, which means "x in units of meters."

To find the position of the object at a specific instant, we can either read off the position from the graph or substitute that instant into the function. For example, "$x(t = 0.2\text{ s})$" gives the position of the object at the instant $t = 0.2$ s; this position can be obtained by substituting 0.2 s for t in the mathematical expression for $x(t)$.

EXAMPLE 2.2 Mathematical representation

The curve in Figure 2.8 can be mathematically represented by the function $x(t) = a + bt + ct^2$, where $a = 0.50$ m, $b = +2.0$ m/s, and $c = -2.0$ m/s^2. Use this function to answer the four questions in Example 2.1.

❶ **GETTING STARTED** This problem requires me to use a mathematical expression rather than a graph to answer questions about the motion of an object.

❷ **DEVISE PLAN** To find the object's position at a given instant, I substitute that instant for t in the function given in the problem and compute the value of x. To find the instant at which the object is at a given position, I substitute that position for x in the function given in the problem and solve for t.

❸ **EXECUTE PLAN** (*a*) Substituting $t = 0.50$ s into the function, I find for the position at $t = 0.50$ s: $x(t = 0.50\text{ s}) = 0.50\text{ m} + (+2.0\text{ m/s})(0.50\text{ s}) + (-2.0\text{ m/s}^2)(0.50\text{ s})^2 = +1.0$ m. ✔

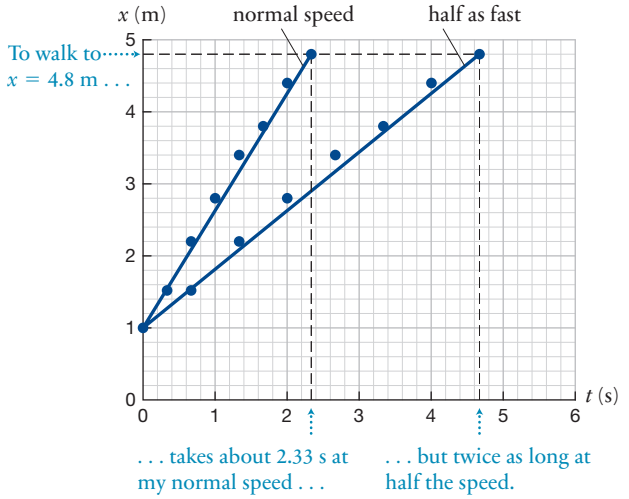
(*b*) To find the instants at which the object reached $x = +0.80$ m, I must set x in the mathematical function equal to $+0.80$ m: $+0.80\text{ m} = 0.50\text{ m} + (+2.0\text{ m/s})t + (-2.0\text{ m/s}^2)t^2$ or, simplifying the equation by omitting the units, $(2.0)t^2 - (2.0)t + 0.30 = 0$. This is a quadratic equation in t, which has two solutions: $t = [2.0 \pm \sqrt{4.0 - 4 \times 2.0 \times 0.30}]/(4.0)$. Working out this expression yields $t = 0.18$ s and $t = 0.82$ s. ✔

(*c*) At $t = 0.80$ s, the object's position is $x(t = 0.80\text{ s}) = 0.50\text{ m} + (+2.0\text{ m/s})(0.80\text{ s}) + (-2.0\text{ m/s}^2)(0.80\text{ s})^2 = +0.82$ m. At $t = 1.2$ s, the object is at $x = 0.50\text{ m} + (+2.0\text{ m/s})(1.2\text{ s}) + (-2.0\text{ m/s}^2)(1.2\text{ s})^2 = +0.02$ m. The distance it traveled is the difference between these two positions: $x(t = 0.80\text{ s}) - x(t = 1.2\text{ s}) = +0.82\text{ m} - (+0.02\text{ m}) = 0.80$ m. ✔

(*d*) I begin by calculating at what instant the object reached $x = +1.0$ m. Substituting this value into the mathematical expression yields $1.0\text{ m} = 0.50\text{ m} + (+2.0\text{ m/s})t + (-2.0\text{ m/s}^2)t^2$ or, simplifying the equation by omitting the units, $-(2.0)t^2 + (2.0)t + 0.50 = 1.0$. Solving this quadratic equation yields $t = 0.50$ s. Next I must find the instant at which the object reached $x = 0$. Following the same procedure, I find two solutions: $t = -0.20$ s and $t = 1.2$ s. The first solution is before the starting point of the motion represented in Figure 2.8, and so I use the second solution to find that the object took $1.2\text{ s} - 0.50\text{ s} = 0.7$ s to travel this distance. ✔

❹ **EVALUATE RESULT** To check my work, I can compare my answers with the ones I obtained in Example 2.1. Indeed, my answers are the same as (or very close to) the ones I obtained from reading the graph.

2.4 Average speed and average velocity



Now that you know how to represent motion in terms of position and time, let us use this information to calculate first the average speed and then the average velocity of the motion.

First, average speed. The more slowly I move, the larger the time interval I require to travel a given distance. Suppose, for instance, I had walked twice as slowly while the camera was rolling. I would have taken twice as much time to get to, say, the end of the forward part of my walk, which is the point $x = +4.8$ m in Figure 2.6. The distance traveled from my starting point would have been the same as before ($4.8\text{ m} - 1.0\text{ m} = 3.8$ m), but it would have taken 4.67 s to reach this point rather than the 2.33 s shown in Figure 2.6. This difference is shown in **Figure 2.9**.

The rate at which an $x(t)$ curve rises with increasing time is called the *slope* of the curve. Notice how the slope becomes less steep when the speed decreases.

2.7 For each speed in Figure 2.9, what are (*a*) the distance traveled between $t = 0$ and $t = 1.50$ s and (*b*) the ratio of the distance traveled to the corresponding time interval? For each speed, what are (*c*) the time interval required to move from $x = 2.00$ m to $x = 3.50$ m and (*d*) the ratio of the distance traveled to the corresponding time interval?

Figure 2.9 Forward motion at two speeds. Walking half as fast means taking twice as long to travel the same distance. To get to the arbitrary point $x = 3.5$ m, for example, takes about 3.0 s at half speed but only about 1.5 s at normal speed.

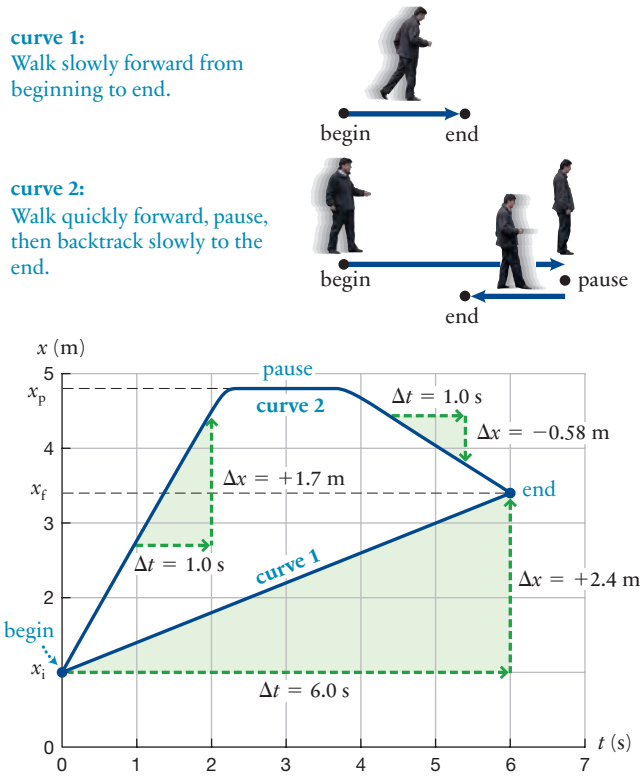
CONCEPTS

This checkpoint reveals how to extract speed from an $x(t)$ curve: Divide the distance traveled by the time interval required to travel this distance. The ratios of parts *b* and *d* correspond to the slopes of the lines in Figure 2.9 and bear out what I said before: The steeper the slope (the higher the number you got for your ratios), the higher the speed.

Suppose someone rode a bicycle 20 km in 2 h. Using the above procedure to calculate the cyclist's speed, we get $(20\text{ km})/(2\text{ h}) = 10\text{ km/h}$. This doesn't necessarily mean the speed was constant—the person could have, for instance, gone much faster than 10 km/h and taken a break somewhere in the middle of the trip. From the data provided, we can say only that the person's speed was 10 km/h *on average*. Hence:

An object's average speed is the distance traveled divided by the time interval required to travel that distance.

Note that this definition involves the *distance traveled* and not the *x component of the displacement*. To see why, let us again use the data from my walk. According to Table 2.1, the *x* component of my displacement was (final position) − (initial position) = (+3.4 m) − (+1.0 m) = +2.4 m over the 6.0-s duration of the trip. The distance I traveled, on the other hand, is the sum of my forward and backward distances: 4.8 m − 1.0 m = 3.8 m for the forward part and 4.8 − 3.4 = 1.4 m for the backward part. Thus the distance I traveled in 6 s was 5.2 m, so my average speed was (5.2 m)/(6.0 s) = 0.87 m/s, *not* (2.4 m)/(6.0 s) = 0.40 m/s.



If I had walked at a constant speed of 0.40 m/s for 6 s, my $x(t)$ curve would be curve 1 in **Figure 2.10**. A constant speed of 0.40 m/s implies that I traveled 0.40 m every second. More generally, a constant speed during a given time interval means that when the time interval is divided into any number of equal-sized subintervals, the distance traveled is the same in all subintervals. A constant speed therefore shows up as a straight line in a position-versus-time graph.

Instead of walking at a constant speed from the initial position x_i directly to the final position x_f in Figure 2.10, however, I got to x_f by first walking beyond that point and then walking back, as illustrated by curve 2 in Figure 2.10.

2.8 (*a*) At what instant did I first pass the position $x_f = +3.4$ m (see curve 2 in Figure 2.10)? (*b*) What was my average speed up to that instant?

In Figure 2.10 let us use the symbol x_p to denote the point at which I paused in my walk. Walking forward, I traveled $x_p - x_i = 4.8\text{ m} - 1.0\text{ m} = +3.8$ m in 2.3 s,

Figure 2.10 Two of the infinite number of ways for getting from an initial position x_i to a final position x_f. Curve 1: walking in one direction only; curve 2: walking beyond the endpoint and then backtracking. Both ways result in a displacement of +2.4 m in 6 s.

and so my average speed was $(3.8\text{ m})/(2.3\text{ s}) = 1.7$ m/s. After pausing for 1.3 s, I traveled the distance $x_p - x_f = 4.8\text{ m} - 3.4\text{ m} = 1.4$ m in $6.0\text{ s} - 3.6\text{ s} = 2.4$ s. So the average speed at which I walked backward was $(1.4\text{ m})/(2.4\text{ s}) = 0.58$ m/s. My higher forward speed is shown in Figure 2.10 by the steeper slope of curve 2 between x_i and x_p.

In a graph of position versus time, the steeper the slope of the curve, the higher the speed.

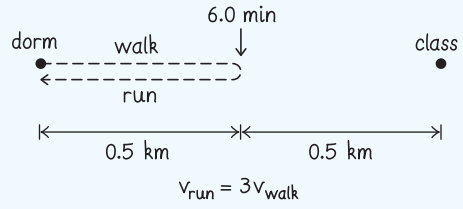
Another point to note about curve 2 in Figure 2.10 is that the curve slopes up from x_i to x_p and down from x_p to x_f. The reason is that I moved in the direction of increasing *x* from x_i to x_p and in the direction of decreasing *x* from x_p to x_f. Average speed, as we defined it, tells us only how fast something moves without indicating the direction in which the motion takes place. In contrast, the slope of an $x(t)$ curve tells us both how fast and in what direction an object is moving. Motion in the positive *x* direction gives a rising $x(t)$ curve and positive slope; motion in the negative *x* direction gives a falling $x(t)$ curve and a negative slope.

The quantity that gives us both the speed and the direction of travel is **velocity.** Like displacement, velocity can be represented by an arrow (more on these arrows and their representation in the second part of

CONCEPTS

this chapter). For now, we define the *x component of the average velocity* as follows:

The *x* component of an object's average velocity is the *x* component of its displacement divided by the length of the time interval taken to travel that displacement.



As before, the term *x component* serves to remind us that this quantity depends on the choice of axis and that it can be both positive and negative (in contrast to *average speed*, which is always positive). For motion in the positive *x* direction, the *x* component of the average velocity is positive; for motion in the negative *x* direction, it is negative. Just as we are doing for the *x* component of the displacement, we indicate the direction of motion along the *x* axis by using an algebraic sign. For example, in going from x_i to x_p along curve 2 in Figure 2.10, the *x* component of my average velocity is +1.7 m/s, meaning the motion is in the positive *x* direction; from x_p to x_f it is −0.58 m/s. (My *speed*, however, was 1.7 m/s between x_i and x_p and 0.58 m/s between x_p and x_f. Speed has no direction and therefore carries no algebraic sign.)

EXAMPLE 2.3 Speed and velocity

With about 20 min to spare, you walk leisurely from your dorm to class, which is 1.0 km away. Halfway there, you realize you have forgotten your notebook and run back to your dorm. You walked 6.0 min before turning around, and you travel three times as far per unit of time running as you do when walking. What are (*a*) the *x* component of your average velocity and (*b*) your average speed over the entire trip?

❶ **GETTING STARTED** To begin this problem, it helps to make a sketch to visualize the situation (**Figure 2.11**).

Figure 2.11

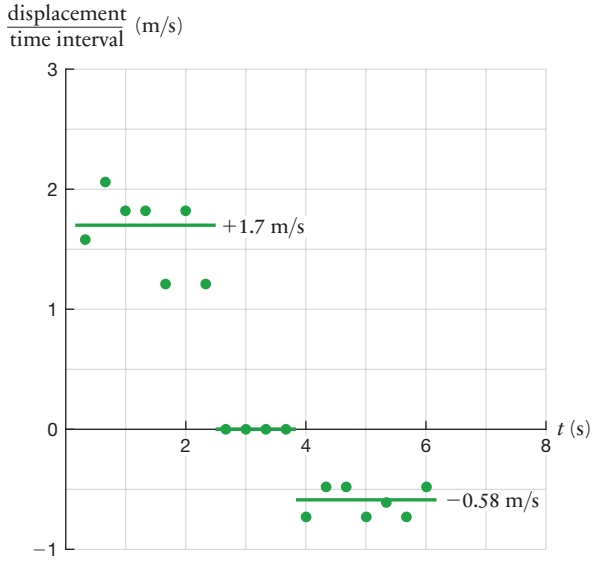
❷ **DEVISE PLAN** To find the *x* component of your average velocity, I need to divide the *x* component of your displacement by the time interval over which this displacement took place. To find your average speed, I must divide the distance traveled by the time interval.

❸ **EXECUTE PLAN** (*a*) When you are back at the dorm, the *x* component of your displacement is zero because your initial and final positions are the same. Therefore the *x* component of your average velocity, (*x* component of the displacement)/(time interval), is zero too. ✔

(*b*) Because you traveled halfway to class and back, and the distance between your dorm and the classroom is 1 km, the distance you traveled by the time you returned to your dorm is 1.0 km. You walked for 6.0 min before turning around. Because you run three times as fast as you walk, it takes you only 2.0 min to return to your dorm, and so the total round-trip time is 8.0 min, or 480 s. Your average speed therefore is (distance traveled)/(time interval)=(1000 m)/(480 s)= 2.1 m/s. ✔

❹ **EVALUATE RESULT** If you start and end at the same place, your displacement is zero and so your average velocity is zero, regardless of how fast you move. The answer I obtained in part *b* means that you would cover about (2.1 m/s)(3600 s) = 7600 m = 7.6 km in one hour. This speed—(7.6 km/h)/(1.6 km/mi) = 4.7 mi/h—is in the right ballpark for a person doing a combination of walking and running.

2.9 In Example 2.3, what was your average speed during the time interval that you (*a*) walked away from and (*b*) ran back toward your dorm? (*c*) Is the average of your answers to parts *a* and *b* the same as the average speed calculated in Example 2.3? Why or why not?



Let us now return to the motion illustrated in the video clip. In Figure 2.10 we determined the *x* component of the average velocity for my motion in each direction: +1.7 m/s walking forward, zero standing still, and −0.58 m/s walking backward. We can obtain more detailed information by calculating the *x* component of the average velocity from one frame to the next. We can do this by calculating the *x* components of the displacements between successive frames from the values of *x* in Table 2.1. The change in the value of *x* from one frame to the next gives the *x* component of the displacements between frames. If we then divide these displacement values by the time interval between frames (0.33 s), we get values for the *x* component of my average velocity that are averaged over much smaller time intervals than before. The result of this computation is shown in **Figure 2.12**.

The first thing that stands out in this graph is that the *x* component of the average velocity obtained from one frame to another varies quite a bit around the *x* component of the average velocity we calculated before. This variation is due to variations in my speed as I walked and to limits in the accuracy of determining the relatively small displacement values from one frame to the next.

Another striking feature in Figure 2.12 is that the *x* component of the average velocity is *negative* for $t \geq 4$ s. This is because the calculation for the *x* component of the displacement (final *x* coordinate minus initial *x* coordinate) automatically takes into account the direction in which the motion takes place. Between $t = 5.0$ s and 5.3 s, for instance, I moved from $x = +4.0$ m to +3.8 m

CONCEPTS

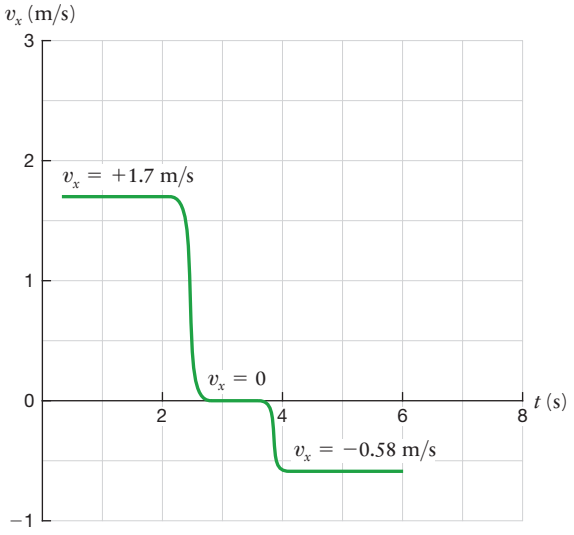


Figure 2.12 Ratio of displacements to time intervals from frame to frame in Figure 2.1.

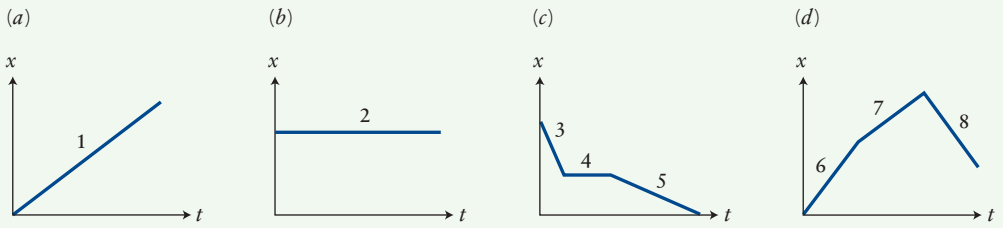
(see Table 2.1), and so the x component of my displacement was $+3.8\text{ m} - (+4.0\text{ m}) = -0.2\text{ m}$. Whenever x decreases, the x component of the displacement is *negative*. The time intervals, on the other hand, are always positive because time runs forward only. Therefore the ratio of the x component of the displacement to the time interval has the same algebraic sign as the x component of the displacement.

Figure 2.13 shows how the x component of the average velocity, denoted by v_x, changes as a function of time. The curve in this figure (which we'll refer to as a

Figure 2.13 Velocity-versus-time graph for the data shown in Figure 2.12.

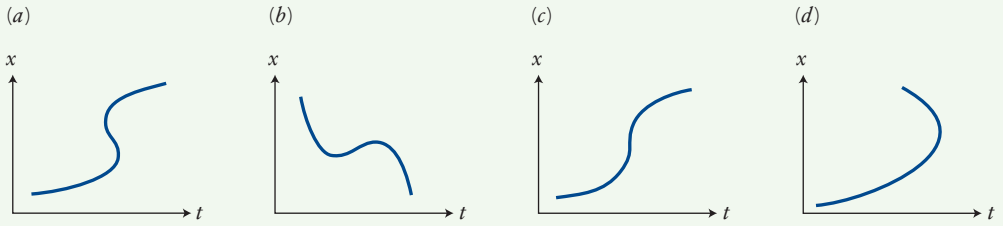
$v_x(t)$ *curve*) contains the same information as the $x(t)$ curve in Figure 2.6. Both are simplified representations of the motion shown in Figure 2.1.



2.10 (*a*) Suppose an object moves from an initial position $x_i = -1.2$ m to a final position $x_f = -2.3$ m without reversing its direction of travel. Is the x component of its average velocity positive or negative? (*b*) Repeat for an object moving from $x_i = +1.2$ m to $x_f = -1.2$ m. (*c*) Do your answers agree with the above statement about the algebraic sign of the x component of the average velocity being the same as the sign of the x component of the displacement?

CONCEPTS

Self-quiz



1. Describe the motion represented by each graph in **Figure 2.14**.

Figure 2.14

2. One or more of the graphs in **Figure 2.15** represent an impossible motion. Identify which ones and explain why the motion is not possible.

Figure 2.15

3. Two cars start from some point P, drive 10 km to a point Q, and then return to P. Car 1 completes the trip in 10 min; car 2 takes 11 min. For each car, what are (*a*) the x component of the average velocity and (*b*) the average speed?

4. Suppose you travel 10 km from P to Q at 10 km/h and another 10 km from Q to R at 20 km/h. What is your average speed during the entire trip from P to R?

5. (*a*) Which of the numbered lines 1–8 in the graphs in Figure 2.14 represents the greatest average speed? (*b*) For which of the numbered lines is the x component of the average velocity negative?

Answers

1. (*a*) An object moving away from the origin at constant speed; (*b*) an object at rest a certain distance from the origin; (*c*) an object moving toward the origin, then pausing halfway between its starting point and the origin, then continuing (more slowly) toward the origin; (*d*) an object moving away from the origin at constant speed for one-third of the time, then continuing in the same direction at a slower constant speed for another third of the time, and finally moving toward the origin at some intermediate constant speed.
2. (*a*) and (*d*). Put the left edge of a ruler along the x axis and slowly slide the ruler to the right. The point where this edge intersects the curve shows the position of the object at the instant indicated by the horizontal axis. For both (*a*) and (*d*) there are instants at which the ruler edge intersects the curve at more than one place for the same value of t. This tells you that these curves are meaningless because no object can be in two places at the same instant.
3. (*a*) The x component of the displacement of both cars is zero because they end where they began. So the x component of their average velocities is zero. (*b*) The distance the two cars travel, however, is 20 km. So the average speed of car 1 is (20 km)/(10 min) = 2.0 km/min, and the average speed of car 2 is (20 km)/(11 min) = 1.8 km/min.
4. If you answered 15 km/h, think again—you cannot simply average the two speeds! To calculate the average speed, you need to know how long the entire trip from P to R took and the distance traveled. The 10 km from P to Q takes (10 km)/(10 km/h) = 1 h; the 10 km from Q to R takes (10 km)/(20 km/h) = 0.5 h, and so the total duration of the trip is 1.5 h. The average speed for the 20-km trip from P to R is thus (20 km)/(1.5 h) = 13 km/h.
5. (*a*) Line 3 because its slope is steepest. (*b*) Lines 3, 5, and 8 because the $x(t)$ curves slope downward with increasing time.

2.5 Scalars and vectors

The physical quantities we use in this book fall into two categories. The first type, called **scalars,** are completely specified by a number, which can be positive or negative, and a unit of measure. An example is temperature, a quantity that is specified completely by a number and a unit (as in 21 °C or 70 °F). The second type, called **vectors,** require, in order to be completely specified, both a magnitude (the "how much" and "of what," specified by a number and a unit) and a direction in space.

EXERCISE 2.4 Scalar or vector?

(*a*) Is the statement *Yesterday the car was parked 3 m from the telephone pole* sufficient to determine the position of the car? Is position a scalar or a vector? (*b*) Is the statement *New York is 200 miles from Boston* sufficient to determine the distance between the two cities? Is distance a vector or a scalar? (*c*) Is the statement *My friend walked 3 m due north from the telephone pole* sufficient to determine your friend's position at the end of her short walk? Is displacement a vector or a scalar?

SOLUTION (*a*) No. The car could have been anywhere on the perimeter of a circle of radius 3 m centered on the telephone pole. A direction is required in addition to a distance, and so position is a vector. ✔

(*b*) Yes. All that is required to specify distance is a number (200) and a unit of length (miles). Because distance does not depend on a direction in space, it is a scalar. ✔

(*c*) Yes. *3 m north* completely specifies your friend's displacement from the telephone pole because it gives both a distance (3 m) and a direction (north). Because it requires a direction, displacement is a vector. ✔

2.11 Are the following quantities vectors or scalars: (*i*) the price of a movie ticket, (*ii*) the average velocity of a ball launched vertically upward, (*iii*) the position of the corner of a rectangle, (*iv*) the length of a side of that rectangle?

Scalars follow the ordinary arithmetic laws of addition, subtraction, multiplication, and division. For example, 2 m + 3 m = 5 m and 2 × 5 s = 10 s. Vectors, on the other hand, obey special laws of addition, subtraction, and multiplication that we begin to discuss in the following sections and then learn about in more detail in Chapter 10.

The only type of motion we study through Chapter 9 is motion in one dimension, which means it occurs either forward or backward along a straight line. For now, therefore, the difference between scalars and vectors is not a major issue because in one dimension the direction of any vector can be specified by an algebraic sign. The difference between scalars and vectors becomes important when we discuss motion in more than one dimension in Chapter 10. It is therefore important that we be able to distinguish vectors from scalars, and so in this book we use arrows to denote vectors:*

$\vec{a}$ vector

b scalar.

The arrow is a reminder that vectors have a direction in space and that they obey rules that are different from those for scalars. Throughout this book, we graphically represent vectors by thick arrows of appropriate

*Note that the direction of the arrow used in the vector notation (that is, the $\rightarrow$ in $\vec{a}$) does not represent the direction of the vector. In particular, it does not reverse direction when we multiply a vector by −1.

length and direction and label these arrows with the corresponding symbol (see, for example, Figures 2.16 and 2.17).

The **magnitude of a vector** tells us how much there is of that vector. In Exercise 2.4*c*, for instance, the magnitude of your friend's displacement is 3 m. When we draw one vector arrow longer than another in a diagram, we are saying that the vector represented by the longer arrow has a magnitude that is greater than the magnitude of the vector represented by the shorter arrow. A magnitude never has a sign associated with it.

There are two common ways of designating the magnitude of a vector symbolically: by drawing vertical lines on either side of its symbol or by removing the overarrow. Thus the magnitude of vector $\vec{b}$ is denoted by either $|\vec{b}|$ or b. In this book, we usually use b for simplicity.

To specify vectors mathematically, we introduce a **unit vector**—a vector whose sole purpose is to define a direction in space. Unit vectors have no units, and the number associated with them (their *magnitude*) is one. They are denoted by a caret or "hat" (ˆ) to distinguish them from ordinary vectors, whose magnitude can have any value; for example, the unit vector pointing in the direction of increasing x along the x axis is denoted by $\hat{\imath}$ (pronounced *i-hat*). In **Figure 2.16*a*** this unit vector is represented by a black arrow that points in the direction of increasing x along the axis. Because unit vectors have a magnitude of 1 and no units, we have

$$|\hat{\imath}| \equiv 1. \tag{2.1}$$

Any vector along the x axis can be written in **unit vector notation** as the product of a scalar and this unit vector:

$$\vec{b} \equiv b_x \hat{\imath} \quad \text{(one dimension)}, \tag{2.2}$$

where b_x is a scalar called the *x component of the vector* $\vec{b}$. The subscript x indicates that the quantity refers to the x axis and reminds you that the sign of b_x depends on our choice of axis direction. If the vector $\vec{b}$ points in the positive x direction (that is, in the direction of $\hat{\imath}$, the direction of increasing x), the scalar b_x is positive. If the vector $\vec{b}$ points in the negative x direction (that is, opposite the direction of $\hat{\imath}$, the direction of decreasing x), the scalar b_x is negative.

If we take the absolute value of Eq. 2.2 and substitute Eq. 2.1, we see that, for vectors in one dimension, the magnitude of the vector $\vec{b}$ is equal to the absolute value of b_x:

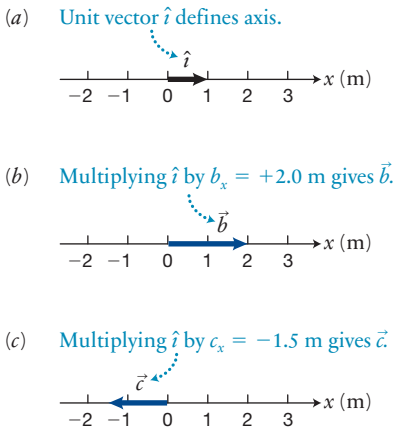
$$b \equiv |\vec{b}| = |b_x \hat{\imath}| = |b_x||\hat{\imath}| = |b_x| \quad \text{(one dimension)}. \tag{2.3}$$

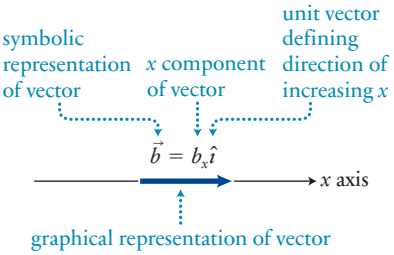
For practice, let us determine the x components of the vectors in Figure 2.16 and also write the vectors in unit vector notation. In Figure 2.16*b*, the vector $\vec{b}$ points in the positive x direction, which means that the scalar b_x (which is the x component of $\vec{b}$) is a positive number. The length of the arrow in Figure 2.16*b* tells us that the magnitude of $\vec{b}$ is 2.0 m (no sign; never a sign for a *magnitude*). From Eq. 2.3, therefore, the absolute value of b_x is 2.0 m. Consequently, the x component of $\vec{b}$ is $b_x = +2.0$ m. In unit vector notation, we write $(+2.0\text{ m})\hat{\imath}$ for our vector $\vec{b}$.

In Figure 2.16*c*, the vector $\vec{c}$ points in the negative x direction, and so the scalar c_x (the x component of c) is a negative number. The magnitude of $\vec{c}$ along the x axis is 1.5 m, which means the absolute value of c_x is 1.5 m. The x component of $\vec{c}$ is thus $c_x = -1.5$ m. In unit vector notation, we write $(-1.5\text{ m})\hat{\imath}$ for our vector $\vec{c}$.

Figure 2.17 summarizes how a vector $\vec{b}$ is represented graphically and mathematically. To remind ourselves that x components are signed numbers, we always show the algebraic sign of a component, even if it is positive

Figure 2.16 The product of a unit vector $\hat{\imath}$ and a scalar b_x yields a vector $\vec{b} = b_x \hat{\imath}$.





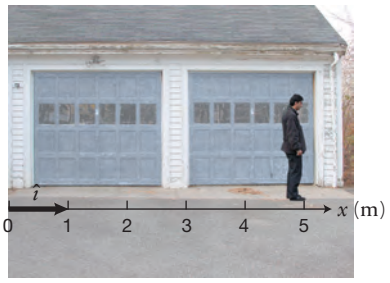


Figure 2.17 Graphical and mathematical representation of a vector.

- magnitude of vector: $b = |b_x|$
- If $b_x > 0$: $\vec{b}$ is in same direction as $\hat{\imath}$
- If $b_x < 0$: $\vec{b}$ is in opposite direction to $\hat{\imath}$

Figure 2.18 The unit vector $\hat{\imath}$ completely specifies a reference axis. The unit vector's direction determines the direction of increasing x along the axis. The tail of the vector locates the origin, and its length defines the unit.

(for instance, $b_x = +2.0$ m). Note also that the x component of a vector always has the same units as the quantity represented by that vector.

In Chapter 10 you'll learn how to mathematically describe vectors that do not lie along the x axis. For motion in one dimension, however, we can always align the axis along the line of motion, and so all vectors can be written in the form given by Eq. 2.2. Because x components are sufficient to completely specify vectors in one dimension, we shall for now work with mostly components rather than vectors.

2.12 Consider the axis and unit vector shown in **Figure 2.18**. Let the vector $\vec{r}$ have its tail at the origin and its tip at my feet. (*a*) What is the x component of that vector? (*b*) Write the vector $\vec{r}$ in terms of its x component and the unit vector. (*c*) What does the vector $\vec{r}$ represent? (*d*) Does $r_x = +2.5$ m unambiguously determine a vector in Figure 2.18? If so, draw the vector, and state what it might represent.

2.6 Position and displacement vectors

Figure 2.19 Superposition of frames 3 and 10 of Figure 2.1. The arrow is my displacement.

The most fundamental vector is displacement, which, as noted in Section 2.2, can be represented graphically by an arrow that points from an object's initial position to its final position. **Figure 2.19**, for example, shows the displacement from my position in frame 3 in Figure 2.1 to my position in frame 10. This vector has a magnitude that is equal to the distance between my initial and final positions (2.6 m), and its direction is toward increasing values of x along the reference axis.

Mathematically we denote displacement by $\Delta\vec{r}$, where the Greek letter Δ (delta) means "the change in" and $\vec{r}$ is a vector specifying position (more on this vector in a bit). The change in a quantity is always taken to be the final value minus the initial value. If your height h increases from 1.75 m to 1.78 m, for instance, the change in your height is $\Delta h = 1.78\text{ m} - 1.75\text{ m} = +0.03$ m. If the number n of cookies in a jar is down to 10 from an initial 12, the change is $\Delta n = 10 - 12 = -2$ cookies.

As we saw in Section 2.2, the x component of the displacement is equal to the change in the x coordinate: $\Delta r_x \equiv \Delta x$. Because of this identity, which is specific to position and displacement, we henceforth denote the x component of the displacement by Δx rather than by Δr_x. So, if the x coordinate of an object changes from some initial value x_i at instant t_i to some final value x_f at some later instant t_f, the x component of the object's displacement is given by

$$\Delta x \equiv x_f - x_i. \tag{2.4}$$

As we saw in Section 2.2, the *x component of the displacement* and the *distance traveled* are not necessarily the same. In particular, if an object turns around during its motion, we need to add the distances between successive turning points (including the initial and final positions) in order to calculate the distance traveled. The **distance** d between two points is equal to the absolute value of the difference in the x coordinates of those two points:

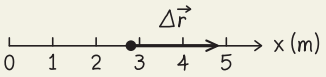
$$d \equiv |x_1 - x_2| \quad \text{(one dimension)}. \tag{2.5}$$

Because distance is obtained by taking the absolute value of a quantity, it is always positive (or zero). Likewise, the distance traveled, which is the sum of the distances between successive points, is always positive (or zero).

EXAMPLE 2.5 Displacement as a vector

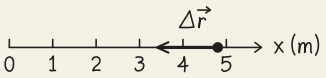
On the reference axis shown in Figure 2.20, draw vectors representing my displacements between the following frames in Figure 2.1: (*a*) 4 and 8, (*b*) 11 and 19, (*c*) 6 and 17. Use the values listed in Table 2.1 to describe each vector in terms of its magnitude and direction.

Figure 2.20 Example 2.5.



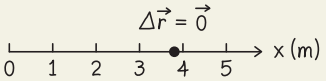
❶ **GETTING STARTED** The pairs of frames given in each part of this example define the initial and final positions. For each pair, I need to determine the displacement vector.

❷ **DEVISE PLAN** I know that a displacement vector points from the initial position to the final position, and so I must draw the tail of the vector at the initial x coordinate and its head at the final x coordinate. Then I can use Eq. 2.3 to determine the magnitude of the displacement vector.



❸ **EXECUTE PLAN** (*a*) The displacement points from my initial position at $x_i = +2.8$ m to my final position at $x_f = +4.8$ m (see Table 2.1). The x component of the displacement is $\Delta x = x_f - x_i = +4.8\text{ m} - (+2.8\text{ m}) = +2.0$ m. The magnitude of this vector is $|\Delta\vec{r}| = |\Delta x| = 2.0$ m; its direction is to the right because the x component is positive (Figure 2.21). ✔

Figure 2.21



(*b*) The displacement points from $x_i = +4.8$ m to $x_f = +3.4$ m. The x component of the displacement is $\Delta x = x_f - x_i = +3.4\text{ m} - (+4.8\text{ m}) = -1.4$ m. The magnitude of this vector is $|\Delta\vec{r}| = |\Delta x| = |-1.4\text{ m}| = 1.4$ m; its direction is to the left because the x component is negative (Figure 2.22). ✔

Figure 2.22

(*c*) The displacement points from $x_i = +3.8$ m to $x_f = +3.8$ m, and thus it has zero magnitude (and no direction, of course; see Figure 2.23). ✔

Figure 2.23

❹ **EVALUATE RESULT** The arrow in part *a* points right, as I would expect because I moved forward (that is, to the right). In part *b* the arrow points left because I moved backward. Even though I moved between frames 6 and 17, I end at my initial position and so the displacement is zero.

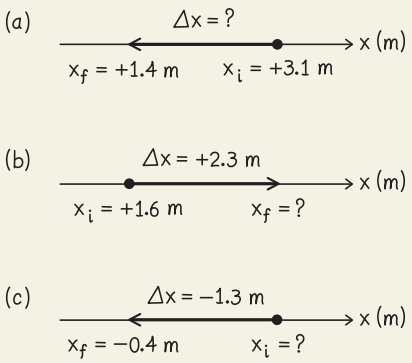
When a vector has zero magnitude as in Example 2.5*c*, we say that it is equal to the *zero vector*, denoted by a zero with an arrow: $\Delta\vec{r} = \vec{0}$. In diagrams, we denote the zero vector by a dot (see Figure 2.23).

2.13 (*a*) What is the x component of the displacement shown in Figure 2.19? (*b*) Write the displacement in terms of its x component and the unit vector.

Rearranging Eq. 2.4, I get an expression for the x coordinate of the final position in terms of the x coordinate of the initial position and the x component of the displacement:

$$x_f = x_i + \Delta x. \tag{2.6}$$

This expression tells you that you can determine the x coordinate of an object's final position by adding the x coordinate of the object's initial position and the x component of its displacement.



EXAMPLE 2.6 Working with displacements

(*a*) An object moves from an initial position at $x_i = +3.1$ m to a final position at $x_f = +1.4$ m. What is the x component of the object's displacement? (*b*) The x component of an object's displacement is $+2.3$ m. If the object's initial position is at $x_i = +1.6$ m, what is the x coordinate of its final position? (*c*) After undergoing a displacement of -1.3 m, an object is at $x_f = -0.4$ m. What is the x coordinate of the object's initial position?

❶ **GETTING STARTED** To visualize what is happening, I begin by making a sketch showing what is given for each situation and which quantities I need to determine (Figure 2.24).

❷ **DEVISE PLAN** The relationship among the initial x coordinate, the final x coordinate, and the x component of the

Figure 2.24

(Continued)

displacement is given by Eqs. 2.4 and 2.6. For each part of the problem, I know two of the three terms in each of these equations, and so I can use them to find the unknown quantity.

3 EXECUTE PLAN (*a*) The x component of the displacement is given by Eq. 2.4:

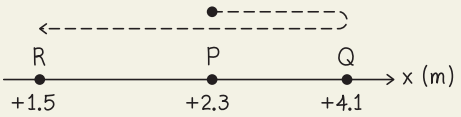
$$\Delta x = x_f - x_i = +1.4\text{ m} - (+3.1\text{ m}) = -1.7\text{ m}. \checkmark$$

(*b*) Using Eq. 2.6, I get

$$x_f = x_i + \Delta x = +1.6\text{ m} + (+2.3\text{ m}) = +3.9\text{ m}. \checkmark$$

(*c*) Rearranging terms in Eq. 2.4, I have

$$x_i = x_f - \Delta x = -0.4\text{ m} - (-1.3\text{ m}) = +0.9\text{ m}. \checkmark$$



4 EVALUATE RESULT In the sketch I made, the displacement in part *a* points to the left, so the x component of the displacement should indeed be negative. In part *b* the displacement is to the right, so the final x coordinate should be larger than the initial x coordinate. For part *c* I expect the initial x coordinate to be positive because the 1.3-m displacement is larger than the distance from the final x coordinate to the origin (0.4 m).

EXAMPLE 2.7 Displacement, distance, distance traveled

An object moves from point P at $x = +2.3$ m to point Q at $x = +4.1$ m and then to point R at $x = +1.5$ m. (*a*) What is the x component of the object's displacement after traveling from P to R? (*b*) What is the distance between the object's initial and final positions? (*c*) What is the distance traveled by the object?

1 GETTING STARTED A simple sketch helps me visualize the motion and the relative locations of P, Q, and R (Figure 2.25).

Figure 2.25

2 DEVISE PLAN For part *a*, I can use Eq. 2.4 to calculate the x component of the object's displacement given x_i and x_f. In parts *b* and *c*, I need to calculate distances, which are given by Eq. 2.5.

3 EXECUTE PLAN (*a*) The object's initial position is at $x_i = +2.3$ m and its final position is at $x_f = +1.5$ m, so the x component of its displacement is (see Eq. 2.4):

$$\Delta x = x_f - x_i = +1.5\text{ m} - (+2.3\text{ m}) = -0.8\text{ m}. \checkmark$$

(*b*) The distance between the initial and final positions is $d = |x_P - x_R| = |+2.3\text{ m} - (+1.5\text{ m})| = 0.8$ m (see Eq. 2.5). ✔

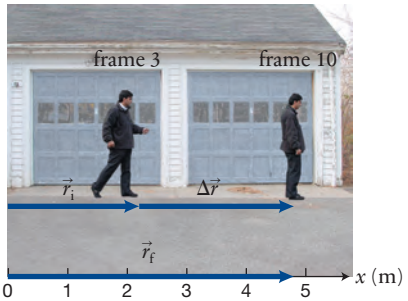
(*c*) The distance between P and Q is $d = |x_P - x_Q| = |+2.3\text{ m} - (+4.1\text{ m})| = 1.8$ m; the distance between Q and R is $d = |x_Q - x_R| = |+4.1\text{ m} - (+1.5\text{ m})| = 2.6$ m. The distance traveled is thus 1.8 m + 2.6 m = 4.4 m. ✔

4 EVALUATE RESULT The sketch shows that the displacement from P to R is in the negative x direction, and so my answer to part *a* should be negative. The distance between P and R is the absolute value of the displacement, and my answer to part *b* is indeed the absolute value of my answer to part *a*. In part *c*, the total distance traveled (4.4 m) is greater than the distance between P and R. The sketch I made readily confirms that this should be the case.

2.14 (*a*) Consider an x axis on which positive values of x are to the right of the origin. For an object initially located to the left of the origin, is the x component of a displacement to the right positive or negative? (*b*) Does the answer to part *a* depend on whether or not the object crosses the origin?

If displacement is a vector, then the position of an object can also be represented by a vector. To see this, multiply Eq. 2.4 through by $\hat{\imath}$:

$$\Delta x\,\hat{\imath} = (x_f - x_i)\hat{\imath} = x_f\,\hat{\imath} - x_i\,\hat{\imath}. \tag{2.7}$$



The left side represents the displacement

$$\Delta x\,\hat{\imath} = \Delta r_x\,\hat{\imath} = \Delta\vec{r}. \tag{2.8}$$

The vector $x_i\,\hat{\imath}$ in Eq. 2.7 is represented in Figure 2.26 by an arrow running from the origin to my initial position. This arrow represents the *position vector* (or simply the **position**)—a vector that lets us determine the position of a point in space relative to some chosen origin. Mathematically, position is represented by the symbol $\vec{r}$. For one-dimensional motion we have

$$\vec{r} \equiv x\,\hat{\imath} \quad \text{(one dimension)}, \tag{2.9}$$

Figure 2.26 Superposition of frames 3 and 10 of Figure 2.1. The arrows show my initial and final positions, $\vec{r}_i$ and $\vec{r}_f$, and the relationship of these vectors to the displacement $\Delta\vec{r}$.

QUANTITATIVE TOOLS

and so we see that the x component of position is equal to the x coordinate: $r_x \equiv x$.

My initial position can be thus written as $x_i\,\hat{\imath} = \vec{r}_i$; my final position is $\vec{r}_f = x_f\,\hat{\imath}$, and so Eq. 2.7 becomes

$$\Delta\vec{r} = \vec{r}_f - \vec{r}_i. \tag{2.10}$$

This equation states that the displacement (the change in position) is equal to the final position minus the initial position. Figure 2.26 graphically shows the relationship between displacement $\Delta\vec{r}$ and the initial and final positions.

EXERCISE 2.8 Displacement and position vectors

(*a*) Write each displacement in Example 2.5 in terms of the unit vector $\hat{\imath}$ shown in Figure 2.18. (*b*) What is the magnitude of each displacement vector in part *a*? (*c*) Write my final position in Figure 2.26 in terms of the unit vector.

SOLUTION

(*a*) $\Delta\vec{r} = (+2.0\text{ m})\hat{\imath}$

$\Delta\vec{r} = (-1.4\text{ m})\hat{\imath}$

$\Delta\vec{r} = (0)\hat{\imath} = \vec{0}$. ✔

(*b*) $|(+2.0\text{ m})| = 2.0\text{ m}$

$|(-1.4\text{ m})| = 1.4\text{ m}$

$|0| = 0$. ✔

(*c*) $\vec{r}_f = (+4.8\text{ m})\hat{\imath}$. ✔

Rearranging Eq. 2.10, we get

$$\vec{r}_f = \vec{r}_i + \Delta\vec{r}, \tag{2.11}$$

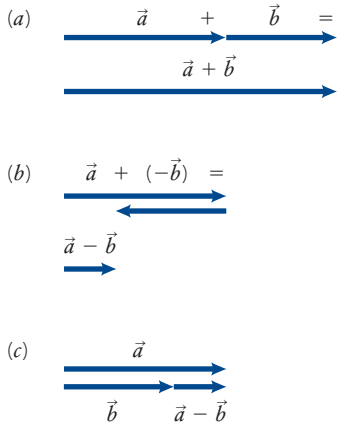
which tells us that the final position is equal to the sum of the initial position and the displacement. Together with Figure 2.26, Eq. 2.11 gives a graphical prescription for adding two vectors:

> **To add two vectors, place the tail of the second vector in the sum at the tip of the first vector; the vector representing the sum runs from the tail of the first vector to the tip of the second.**

Figure 2.27*a* shows this procedure for two arbitrary vectors $\vec{a}$ and $\vec{b}$.

Equation 2.10 also gives us a prescription for subtracting vectors:

$$\Delta\vec{r} = \vec{r}_f - \vec{r}_i = \vec{r}_f + (-1)\vec{r}_i. \tag{2.12}$$



This equation states that we can find the displacement $\Delta\vec{r}$ by subtracting the initial position $\vec{r}_i$ from the final position $\vec{r}_f$ or, alternatively, by adding the vector $(-1)\vec{r}_i$ to $\vec{r}_f$. The vector $(-1)\vec{r}_i$ has the same magnitude as $\vec{r}_i$ but points in the opposite direction. So the graphical prescription for subtracting two vectors is:

> **To subtract a vector from another vector, reverse the direction of the vector being subtracted and add the reversed vector to the vector from which you are subtracting.**

Figure 2.27*b* shows this procedure for two arbitrary vectors $\vec{a}$ and $\vec{b}$.

Figure 2.26 suggests another way of finding the difference between two vectors: The vectors $\vec{r}_i$ and $\vec{r}_f$ both have their tails at the origin, and the

Figure 2.27 (*a*) Adding two vectors. (*b*, *c*) Two ways to subtract one vector from another.

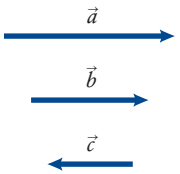
vector $\vec{r}_f - \vec{r}_i$ points from the tip of $\vec{r}_i$ to the tip of $\vec{r}_f$. So an alternative graphical prescription for subtracting two vectors is:

To subtract a vector from another vector, place their tails at the same point and then draw a vector from the tip of the vector being subtracted to the tip of the vector from which you are subtracting.

or

The vector $\vec{a} - \vec{b}$ representing the difference between two vectors $\vec{a}$ and $\vec{b}$ points from the tip of $\vec{b}$ (the vector being subtracted) to the tip of $\vec{a}$.

This approach is illustrated in Figure 2.27*c*.



In later chapters we discuss rules for multiplying vectors. For now it suffices to know how to multiply a vector by a scalar. The effect of such a multiplication is the same as that of multiplying the unit vector by a scalar (see Figure 2.16): Multiplying a vector $\vec{a}$ by a scalar c yields a vector whose length equals the length of the original vector times the scalar:

$$c\,\vec{a} = c(a_x\hat{\imath}) = (ca_x)\hat{\imath}. \tag{2.13}$$

If the scalar c is positive, then the product vector points in the same direction as the original vector $\vec{a}$; if c is negative, the product vector points in the direction opposite that of $\vec{a}$.

Although our current treatment of vectors is limited to one dimension, we shall be able to use the same methods when dealing with vectors in more than one dimension in Chapter 10.

Figure 2.28 Checkpoint 2.15.

2.15 Consider the three vectors illustrated in **Figure 2.28**. (*a*) Make a sketch representing the vectors $\vec{a} + \vec{c}$, $\vec{a} - \vec{b}$, and $\vec{c} - \vec{b}$. (*b*) Are the vectors $\vec{a} + \vec{c}$ and $\vec{c} + \vec{a}$ identical? (*c*) Are the vectors $\vec{c} - \vec{b}$ and $\vec{b} - \vec{c}$ identical?

2.7 Velocity as a vector

Like displacement, average velocity is a vector. As we saw in Section 2.4, by dividing the x component of the displacement by the time interval required for that displacement, we obtain the x component of the average velocity during that time interval. Consider, for example, an object for which the x component of the displacement in the time interval between clock readings t_i and t_f is Δx. We can write the time interval as the change in the clock reading, $\Delta t = t_f - t_i$, and so the x component of the average velocity is

$$v_{x,\text{av}} \equiv \frac{\Delta x}{\Delta t} = \frac{x_f - x_i}{t_f - t_i}. \tag{2.14}$$

As before, the subscript x reminds us that this component is measured relative to our reference axis and that it can be either positive or negative, depending on the sign of Δx (Δt is always positive because $t_f > t_i$).

Equation 2.14 gives us the x component of the vector $\vec{v}_{\text{av}} = v_{x,\text{av}}\,\hat{\imath}$. Multiplying the first and middle terms of Eq. 2.14 by $\hat{\imath}$ and substituting $\Delta\vec{r} = \Delta x\,\hat{\imath}$ (Eq. 2.8), we see that average velocity can be written as

$$\vec{v}_{\text{av}} \equiv v_{x,\text{av}}\,\hat{\imath} = \frac{\Delta\vec{r}}{\Delta t}. \tag{2.15}$$

Because Δt is always positive ($t_f > t_i$), Eq. 2.15 shows that for motion in one dimension, the average velocity $\vec{v}_{\text{av}}$ always points in the same direction as the displacement.

QUANTITATIVE TOOLS

EXAMPLE 2.9 Average velocity and average speed

Consider my motion between frames 1 and 8 in Figure 2.1. Use the values listed in Table 2.1 to determine the answers to these questions: (*a*) What is my average speed over this time interval? (*b*) What is the *x* component of my average velocity over this time interval? (*c*) Write the average velocity in terms of the unit vector $\hat{\imath}$.

❶ **GETTING STARTED** Frames 1 through 8 correspond to my forward motion. To determine my average speed and velocity, I need to know both my displacement between these frames and the time interval between them.

❷ **DEVISE PLAN** I can get the average speed from its definition: the distance traveled divided by the time interval. Because I travel in only one direction between frames 1 and 8, the distance traveled is equal to the distance between my initial and final positions. For part *b*, I can use Eq. 2.14 to get the *x* component of the average velocity, and Eq. 2.15 shows me how to write the average velocity in unit vector form.

❸ **EXECUTE PLAN** (*a*) From Table 2.1, $|x_f - x_i| = |+4.8\text{ m} - (+1.0\text{ m})| = 3.8\text{ m}$. I traveled from x_i to x_f in time interval $\Delta t = 2.3\text{ s}$. My average speed was thus $(3.8\text{ m})/(2.3\text{ s}) = 1.7\text{ m/s}$. ✔

(*b*) The *x* component of my displacement is $\Delta x = x_f - x_i = +4.8\text{ m} - (+1.0\text{ m}) = +3.8\text{ m}$. Using Eq. 2.14, I find for the *x* component of average velocity $v_{x,\text{av}} = \Delta x/\Delta t = (+3.8\text{ m})/(2.3\text{ s}) = +1.7\text{ m/s}$. ✔

(*c*) $\vec{v}_{\text{av}} = \Delta\vec{r}/\Delta t = (+3.8\text{ m})\hat{\imath}/(2.3\text{ s}) = (+1.7\text{ m/s})\hat{\imath}$. ✔

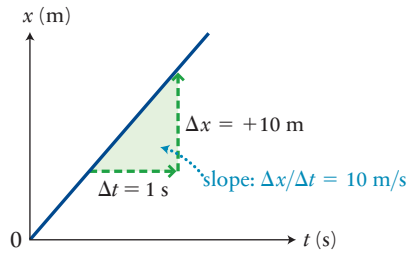
❹ **EVALUATE RESULT** The answer to part *a* shows that I cover a distance roughly equal to my height each second, which is reasonable for a person walking. Because I walk in one direction only, the answer to part *b* has the same value as the answer to part *a*. The positive sign indicates that my motion is in the positive *x* direction, as I expect. My answer to part *c* expresses this result in unit vector form.

2.16 (*a*) Consider my motion between frames 6 and 17 in Figure 2.1. Use the values in Table 2.1 to determine the answers to these questions: What is my average speed over this time interval? What is the *x* component of my average velocity? What is the average velocity? (*b*) Repeat for the motion between frames 1 and 17.

2.8 Motion at constant velocity

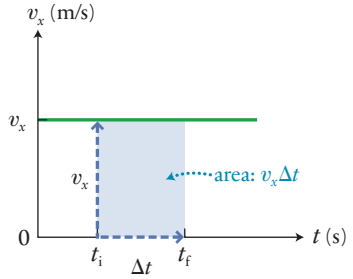
If an object moves at constant velocity, we can drop the term *average* when referring to velocity. When we do so, the *x* component of the average velocity is simply v_x. According to Eq. 2.14, we thus have

$$\Delta x = v_x\,\Delta t \quad \text{(constant velocity)}. \tag{2.16}$$



To give just one example, a car going at a constant velocity of +10 m/s in the *x* direction travels a distance of 10 m during each second of its motion. A plot of position versus time is therefore a straight line, as indicated in **Figure 2.29a**. Recall from Checkpoint 2.7 and the text immediately surrounding it that the ratio $\Delta x/\Delta t$ is the slope of the $x(t)$ curve. Looking at Figure 2.29*a*, you can see that this ratio $\Delta x/\Delta t$ is the tangent of the angle that the $x(t)$ curve makes with any horizontal line drawn through the curve. So we see that for motion at constant velocity, the slope of the $x(t)$ curve is numerically equal to the *x* component of the velocity:

$$\frac{\Delta x}{\Delta t} = v_x \quad \text{(constant velocity)}. \tag{2.17}$$



Another useful fact can be obtained by looking at the $v_x(t)$ curve for an object moving at constant velocity. Because the *x* component of the velocity always has the same value when the velocity is constant, this curve is a horizontal line, as shown in Figure 2.29*b*. Notice that the area $v_x\,\Delta t$ (height times width) of the shaded rectangle of width Δt under this line is, from Eq. 2.16, equal to the *x* component of the displacement, Δx, during the time interval.* This is true for any time interval Δt, and so:

Figure 2.29 Graphs of position and velocity as a function of time for an object moving at constant velocity.

(*a*) Position versus time: straight line with nonzero slope

(*b*) Velocity versus time: horizontal line

*The word *area* requires some caution here: The height of the rectangle represents the *x* component of a velocity (in meters per second), and the width represents a time interval (in seconds), and so the product—the "area"—has units of (m/s) × s = m, not m^2 as would a surface area in the traditional sense. This is so because the area of the rectangle, $v_x\,\Delta t = \Delta x$, represents the *x* component of a displacement, which has units of meters.

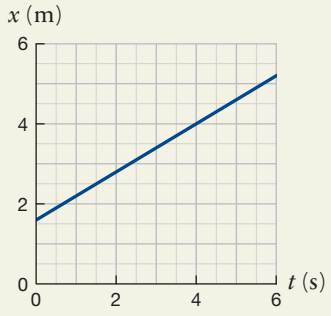
The x component of the displacement during any time interval is given by the area under the $v_x(t)$ curve between the beginning and the end of the time interval.

Because the x component of the velocity can be positive or negative, the area can also be positive or negative, as it should given that it represents the x component of a displacement. As we shall see in Chapter 3, this correspondence between the x component of the displacement and the area under the $v_x(t)$ curve holds not just for motion at constant velocity but for any type of motion.

For an object moving at constant velocity, Eq. 2.16 gives us a way of determining the x coordinate of the position of the object at any time. Remembering that $\Delta x = x_f - x_i$, we can write Eq. 2.16 in the form

$$x_f - x_i = v_x \Delta t \quad \text{(constant velocity)}, \tag{2.18}$$

or, solving for x_f,



$$x_f = x_i + v_x \Delta t \quad \text{(constant velocity)}. \tag{2.19}$$

This expression allows us to determine, at any time t_f, the x coordinate of the position of an object moving at constant velocity, provided we know the object's initial position coordinate x_i at time t_i.

EXAMPLE 2.10 Motion at constant velocity

Figure 2.30 shows the position-versus-time graph for part of the motion of an object moving at constant velocity. (*a*) What is the x component of the object's velocity? (*b*) Write an expression for $x(t)$, the x coordinate of the position of the object at an arbitrary time t. (*c*) What is the x coordinate of the object's position at $t = 25$ s?

Figure 2.30 Example 2.10.

❶ **GETTING STARTED** The $x(t)$ curve in Figure 2.30 is a straight line, as it should be for a motion at constant velocity. To answer the question, I have to read off information from the graph.

❷ **DEVISE PLAN** The x component of the object's velocity is given by Eq. 2.14. Once I have found this value, I can use Eq. 2.19 to answer part *b*. Although the graph doesn't show the position of the object at $t = 25$ s, I can use my solution to part *b* to find the position by substituting $t = 25$ s.

❸ **EXECUTE PLAN** (*a*) From the graph I see that the object's position changes from $x_i = +1.6$ m to $x_f = +5.2$ m in the time interval between $t_i = 0$ and $t_f = 6.0$ s. Substituting these values into Eq. 2.14, I find for the x component of the velocity:

$$v_x = \frac{x_f - x_i}{t_f - t_i} = \frac{+5.2\text{ m} - (+1.6\text{ m})}{6.0\text{ s} - 0} = \frac{+3.6\text{ m}}{6.0\text{ s}}$$
$$= +0.60\text{ m/s}. \checkmark$$

(*b*) I take the object's position at $t = 0$ as the initial position. Substituting $t_i = 0$, $x_i = +1.6$ m, and $v_x = +0.60$ m/s from part *a* into Eq. 2.19, I get

$$x_f = +1.6\text{ m} + (+0.60\text{ m/s})(t_f - 0)$$
$$= +1.6\text{ m} + (+0.60\text{ m/s})t_f.$$

Because the choice of t_f is arbitrary, I may just as well write, for the x coordinate of the position at any instant of time t:

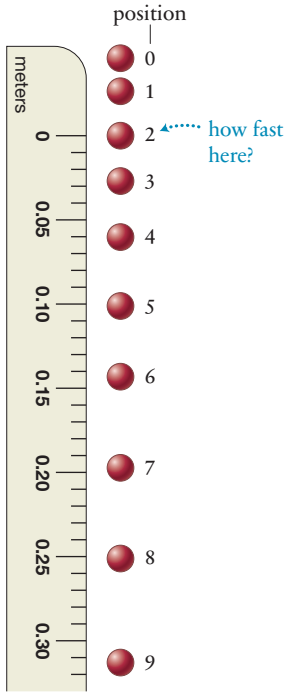
$$x(t) = +1.6\text{ m} + (+0.60\text{ m/s})t. \checkmark$$

(*c*) Substituting $t = 25$ s into the expression I obtained in part *b* yields

$$x(t = 25\text{ s}) = +1.6\text{ m} + (+0.60\text{ m/s})(25\text{ s})$$
$$= +1.6\text{ m} + 15\text{ m} = +17\text{ m}. \checkmark$$

❹ **EVALUATE RESULT** The x component of the object's velocity is positive, as I would expect from the positive slope of the $x(t)$ curve. I can double-check the value (0.60 m/s) by reading off the increase in x over a 1-s interval in the graph. The result is indeed about 0.6 m. I cannot read off the value for x for $t = 25$ s from the graph because the graph extends to only $t = 6$ s. However, from the graph I see that the object starts near $x = 2$ m and the x coordinate increases by 3 m every 5 s. In 25 s, the object displacement should therefore be $5(3\text{ m}) = 15$ m, and so the object's final position should be near $(2\text{ m}) + (15\text{ m}) = 17$ m, which is what I got.

QUANTITATIVE TOOLS



2.17 In Example 2.10, suppose I had taken x_i to be the x coordinate of the object's position not at $t = 0$ but at $t = 2.0$ s. Show that the expression for the x coordinate of the position is the same as the one I obtained in Example 2.10*b*.

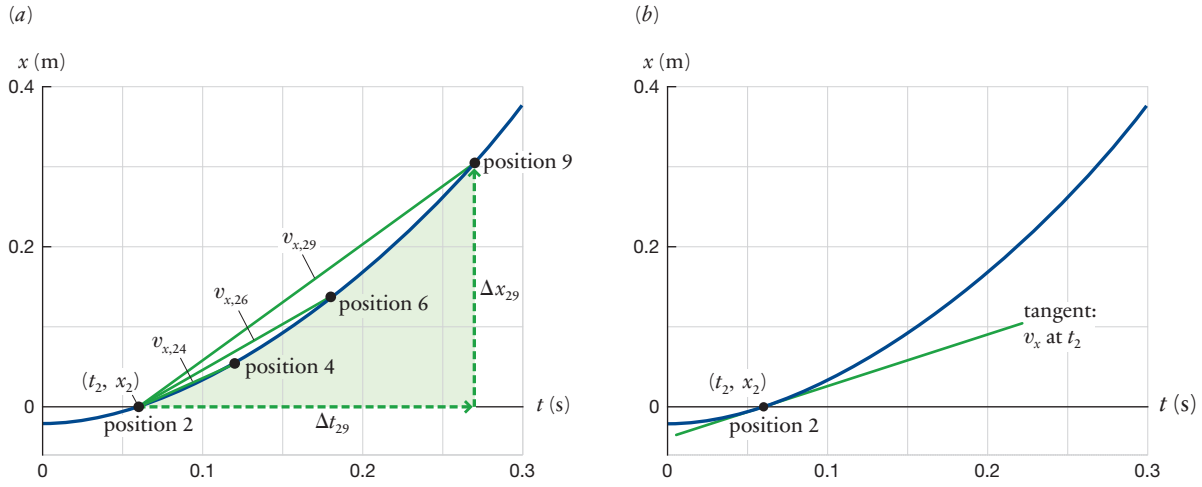
2.9 Instantaneous velocity

If you are driving and wonder How fast am I going *now*?, the answer to your question is provided by the speedometer. This gauge gives your *instantaneous speed*, which is generally not equal to your average speed during the entire trip. Likewise, if you drop a ball from a certain height, the ball speeds up as it falls, and so its velocity changes over time. In addition to being able to calculate the ball's average velocity as it falls over a certain distance, you might be interested in knowing its velocity at any given instant—its **instantaneous velocity.**

Figure 2.31 shows successive positions of a falling ball at 0.0300-s time intervals. Such a picture can be obtained using a strobe light to illuminate the ball at fixed intervals and thus record its position at fixed intervals. As the ball falls, the positions at which it is photographed get farther and farther apart. In other words, the magnitude of the ball's displacement per time interval (the magnitude of its average velocity, from Eq. 2.15) increases. Suppose we want to find the ball's velocity at position 2: We want to answer the question How fast is the ball moving at the instant it passes position 2? Using the ruler in the picture, we can measure how long the ball takes to fall a certain distance after position 2, but doing that gives the ball's *average* velocity over that distance. To get a value closer to the ball's instantaneous velocity at position 2, we have to make the time interval over which we measure the distance shorter and shorter.

Figure 2.31 Successive positions of a falling ball recorded at 0.0300-s intervals.

From here on, the word *velocity* without any adjective is used to designate the instantaneous value of the velocity. When we are interested in the average value over a certain time interval, we shall always use the adjective *average*. In equations we drop the subscript av when we mean the instantaneous value—by convention, $\vec{v}_{av}$ = average velocity, $\vec{v}$ = instantaneous velocity. Likewise, *speed* always means *instantaneous speed*.



2.18 (*a*) Determine the x component of the ball's average velocity between positions 2 and 9 in Figure 2.31. (*b*) Repeat between positions 2 and 8. (*c*) Repeat for increasingly smaller time intervals. (*d*) As the time interval decreases, does the x component of the average velocity increase, decrease, or stay the same? Explain. (*e*) Plot the x components of the average velocity you obtained in parts *a*–*c* versus the length of the time interval. (*f*) Do you expect the x component of the average velocity to become zero as the time interval approaches zero?

Figure 2.32 shows the position of the ball as a function of time, as obtained from Figure 2.31. The x component of the average velocity measured over an interval Δt is given by Eq. 2.14, and in Checkpoint 2.18 you used that equation to evaluate the x component of the average velocity between positions 2 and 9:

$$v_{x,29} = \frac{x_9 - x_2}{t_9 - t_2}. \qquad (2.20)$$

(I substituted 29 for the subscript av to indicate that we are averaging over the time interval between t_2 and t_9.) This calculation yields the slope of the hypotenuse of the right triangle between positions 2 and 9 in Figure 2.32*a*. As you reduced the size of Δt, you got closer and closer to the value of the velocity at position 2. As the checkpoint shows, the x component of the displacement

Figure 2.32 Procedure for finding the x component of the velocity of the ball in Figure 2.31 from its $x(t)$ curve. (*a*) As we reduce the time interval $\Delta t = t_f - t_2$ over which the x component of the velocity is averaged, Δx shrinks and the straight line between (x_2, t_2) and (x_f, t_f) approaches the tangent to the curve at (x_2, t_2). (*b*) The slope of the tangent at (x_2, t_2) gives the x component of the velocity at that point.

gets smaller as Δt gets smaller, but the ratio of the two (the slope of the hypotenuse) never becomes zero. This is not surprising because the x component of the ball's average velocity had some positive value while passing position 2. Thus that component should also be nonzero at position 2.

Letting the interval Δt approach zero, we obtain the x component of the velocity at instant t:

$$v_x \equiv \lim_{\Delta t \to 0} \frac{\Delta x}{\Delta t}. \tag{2.21}$$

The right side of this equation is the definition of the *derivative* of x with respect to time:

$$v_x \equiv \frac{dx}{dt}. \tag{2.22}$$

As you can see from Figure 2.32, the hypotenuse of the triangle spanned by the time interval Δt approaches the tangent to the $x(t)$ curve at time t_2, when Δt goes to zero. The x component of the velocity at instant t is thus equal to the slope of the tangent to the $x(t)$ curve at instant t.

The velocity (which is a vector) is then

$$\vec{v} = v_x \hat{\imath} = \left(\lim_{\Delta t \to 0} \frac{\Delta x}{\Delta t} \right) \hat{\imath}. \tag{2.23}$$

Because the unit vector is constant, we can pull it inside the parentheses and write

$$\left(\lim_{\Delta t \to 0} \frac{\Delta x}{\Delta t} \right) \hat{\imath} = \lim_{\Delta t \to 0} \frac{\Delta x\, \hat{\imath}}{\Delta t} = \lim_{\Delta t \to 0} \frac{\Delta \vec{r}}{\Delta t}, \tag{2.24}$$

where I have used the relationship $\Delta \vec{r} = \Delta x\, \hat{\imath}$ from Eq. 2.8. The term on the right in Eq. 2.24 is the derivative of the position vector, and so we can write

$$\vec{v} = \frac{d\vec{r}}{dt}. \tag{2.25}$$

The magnitude of this vector is the **speed** $v = |\vec{v}|$.

Table 2.2 Symbols and their meaning

Symbol	Meaning
t	clock reading = instant in time
$\Delta t \equiv t_f - t_i$	change in clock reading = interval of time
x	x coordinate
$d \equiv \lvert x_1 - x_2 \rvert$	straight-line distance between two points (never has sign)
$\hat{\imath}$	unit vector defining direction of x axis (vector magnitude 1)
$\vec{b} \equiv b_x \hat{\imath}$	vector and unit vector notation (see examples below)
b_x	x component of vector $\vec{b}$ (can be positive or negative)
$b \equiv \lvert\vec{b}\rvert = \lvert b_x \rvert$	magnitude of vector $\vec{b}$ (always positive)

Vector	Meaning	Component	Meaning
$\Delta\vec{r} = \Delta r_x \hat{\imath}$	displacement	$\Delta r_x \equiv \Delta x$	x component of displacement = change in x coordinate
$\vec{r} = r_x \hat{\imath}$	position	$r_x \equiv x$	x component of position = x coordinate
$\vec{v}_{av} = v_{x,av} \hat{\imath}$	average velocity	$v_{x,av} \equiv \dfrac{\Delta x}{\Delta t}$	x component of average velocity
$\vec{v} = v_x \hat{\imath}$	(instantaneous) velocity	$v_x \equiv \lim\limits_{\Delta t \to 0} \dfrac{\Delta x}{\Delta t} \equiv \dfrac{dx}{dt}$	x component of (instantaneous) velocity

Table 2.2 summarizes the various symbols we have introduced in this chapter and their meaning.

EXAMPLE 2.11 Time intervals and derivatives

Suppose the x coordinate of the position of an object moving along the x axis varies in time according to the expression $x(t) = ct^3$, where c is a constant. Derive an expression for the x component of the velocity as a function of time.

❶ **GETTING STARTED** There are two ways to obtain the answer to this problem. One is to use differential calculus: The x component of the velocity is the derivative of the function $x(t)$ with respect to time. The other way is to evaluate the x component of the velocity over a finite time interval Δt and then let that interval go to zero. If I use both methods, I can easily verify my answer.

❷ **DEVISE PLAN** I'll use the (harder) second method first. To do so, I have to determine the change in the x coordinates between two instants t_i and $t_f = t_i + \Delta t$. The x component of the average velocity is then the ratio of this change in the x coordinate and Δt. Equation 2.21 then allows me to find the x component of the (instantaneous) velocity at any instant by taking the limit of this result as Δt goes to zero.

❸ **EXECUTE PLAN** The x coordinate of the object's initial position at time t_i is $x_i = ct_i^3$. At a later time $t_f = t_i + \Delta t$, the x coordinate of the position is

$$\begin{aligned} x_f &= ct_f^3 = c(t_i + \Delta t)^3 \\ &= ct_i^3 + 3ct_i^2\Delta t + 3ct_i(\Delta t)^2 + c(\Delta t)^3. \end{aligned}$$

Therefore the x component of the displacement in the time interval Δt is

$$\begin{aligned} \Delta x &= x_f - x_i \\ &= [\,ct_i^3 + 3ct_i^2\Delta t + 3ct_i(\Delta t)^2 + c(\Delta t)^3\,] - ct_i^3 \\ &= 3ct_i^2\Delta t + 3ct_i(\Delta t)^2 + c(\Delta t)^3. \end{aligned}$$

The x component of the average velocity is thus

$$v_{x,av} = \frac{\Delta x}{\Delta t} = 3ct_i^2 + 3ct_i\Delta t + c(\Delta t)^2.$$

If I let Δt approach zero, the second and third terms on the right go to zero, so that I have

$$v_x = \lim_{\Delta t \to 0} \frac{\Delta x}{\Delta t} = 3ct^2, \checkmark$$

where I have dropped the subscript i because the result holds for any instant t. This equation gives the velocity at any time t. It tells me that v_x changes as the square of t.

❹ **EVALUATE RESULT** I can verify my result using differential calculus:

$$v_x(t) = \frac{d}{dt}x(t) = \frac{d}{dt}(ct^3) = 3ct^2.$$

EXAMPLE 2.12 The limiting process

Consider again an object moving along the x axis according to the expression $x(t) = ct^3$, with $c = +0.12\ \text{m/s}^3$. (*a*) Determine the x component of the object's average velocity during the interval from $t_i = 1.0$ s to $t_f = 2.0$ s. (*b*) Repeat for the interval from $t_i = 1.0$ s to $t_f = 1.1$ s. (*c*) Show that your result approaches the x component of the velocity at $t = 1.0$ s if you continue to reduce the interval by factors of 10. Ignore the significant digits rules taught in Chapter 1. Instead, use all the digits your calculator shows in every step.

❶ **GETTING STARTED** I have to use a fixed initial instant ($t_i = 1.0$ s) and evaluate the change in the function $x(t)$ over increasingly smaller time intervals Δt, starting with $\Delta t = 1.0$ s.

❷ **DEVISE PLAN** Evaluating the change in $x(t)$ is just a matter of doing it, and so my plan is to roll up my sleeves and dig in!

❸ **EXECUTE PLAN** (*a*) At $t_i = 1.0$ s, the object is at $x_i = (+0.12\ \text{m/s}^3)(1.0\ \text{s})^3 = +0.12$ m. At $t_f = 2.0$ s, it is at $x_f = (+0.12\ \text{m/s}^3)(2.0\ \text{s})^3 = +0.96$ m, and so $\Delta x = +0.96\ \text{m} - (+0.12\ \text{m}) = +0.84$ m. The x component of the average velocity therefore is $(\Delta x)/(\Delta t) = (+0.84\ \text{m})/(1.0\ \text{s}) = +0.84$ m/s. ✔
(*b*) Between $t_i = 1.0$ s and $t_f = 1.1$ s, I have $\Delta x = (+0.12\ \text{m/s}^3)(1.1\ \text{s})^3 - (+0.12\ \text{m}) = +0.039\,72$ m, and $v_{x,\text{av}} = (+0.039\,72\ \text{m})/(0.10\ \text{s}) = +0.3972$ m/s. ✔

Table 2.3 Example 2.12

Δt (s)	Δx (m)	$v_{x,\text{av}} = \Delta x/\Delta t$ (m/s)
1	+0.84	+0.84
0.1	+0.039 72	+0.3972
0.01	+0.003 636 12	+0.363 612
0.001	+0.000 360 360 12	+0.360 360 12
0.0001	+0.000 036 003 600 12	+0.360 036 0012
0.000 01	+0.000 003 600 036 00	+0.360 003 6000
0.000 001	+0.000 000 360 000 36	+0.360 000 3600
0.000 0001	+0.000 000 036 000 00	+0.360 000 0362

(*c*) Table 2.3 shows what happens as I continue to shorten the time interval by factors of 10. As Δt becomes smaller and smaller, $v_{x,\text{av}}$ approaches 0.36 m/s. ✔

❹ **EVALUATE RESULT** If I substitute $c = +0.12\ \text{m/s}^3$ and $t = 1.0$ s into the expression for the x component of the velocity obtained in Example 2.11, I should obtain the same answer as the limiting value for small intervals Δt. Indeed, I find

$$v_x(t) = 3ct^2 = 3(+0.12\ \text{m/s}^3)(1.0\ \text{s})^2 = +0.36\ \text{m/s}.$$

2.19 (*a*) Suppose the position for a certain object is constant. Determine the x component of its velocity by using Eq. 2.22 and by evaluating the limit in Eq. 2.21 of the ratio of the x component of the displacement over a finite time interval. (*b*) Repeat for the case where the x coordinate of the position changes with time according to the expression $x = ct$, where c is a constant. Explain your answer.

Chapter Summary

Average speed and average velocity (Sections 2.2–2.4, 2.6, 2.7)

Concepts The **distance traveled** is the accumulated distance covered by an object along the path of its motion, without regard to direction.

The x component of an object's **displacement** is the change in its x coordinate.

The **average speed** of an object is the distance it travels divided by the time interval it takes to travel that distance.

The x component of an object's **average velocity** is the x component of its displacement divided by the time interval taken to travel that displacement. The magnitude of the average velocity is not necessarily equal to the average speed.

Quantitative Tools The **distance** d between two points x_1 and x_2 is

$$d \equiv |x_1 - x_2|. \quad \text{(one dimension)}. \tag{2.5}$$

The x component of the **displacement** Δx of an object that moves from a point x_i to a point x_f is

$$\Delta x \equiv x_f - x_i. \tag{2.4}$$

The x component of the object's **average velocity** is

$$v_{x,av} \equiv \frac{\Delta x}{\Delta t} = \frac{x_f - x_i}{t_f - t_i}. \tag{2.14}$$

Vectors and scalars (Sections 2.5, 2.6)

Concepts A **scalar** is a physical quantity that is completely specified by a number and a unit of measure. A **vector** is a physical quantity that is completely specified by a number, a unit of measure, and a direction. The number and unit of measure together are called the **magnitude** of the vector.

A **unit vector** has magnitude one and no units.

To **add** two vectors, place the tail of the second vector in the sum at the tip of the first vector; the vector representing the sum runs from the tail of the first vector to the tip of the second. To **subtract** one vector from another, reverse the direction of the vector being subtracted and add the reversed vector to the vector from which you are subtracting.

Quantitative Tools The unit vector $\hat{\imath}$ has magnitude one and points along the x axis in the direction of increasing x.

A vector $\vec{b}$ that points in the x direction and has an x component b_x can be written in **unit vector notation** as

$$\vec{b} \equiv b_x \hat{\imath}. \tag{2.2}$$

Position, displacement, and velocity as vectors (Sections 2.6, 2.7)

Concepts The **position vector,** or **position,** of a point is drawn from the origin of a coordinate system to the point.

The **displacement vector** of an object is the change in its position vector. It is the vector that points from the tip of the original position vector to the tip of the final position vector.

Quantitative Tools The position $\vec{r}$ of a point that has x coordinate x is

$$\vec{r} \equiv x \hat{\imath}. \tag{2.9}$$

The displacement vector $\Delta\vec{r}$ of an object moving along the x axis is

$$\Delta\vec{r} = \vec{r}_f - \vec{r}_i = (x_f - x_i)\hat{\imath}. \tag{2.7, 2.8, 2.10}$$

The average velocity of an object moving along the x axis is

$$\vec{v}_{av} \equiv \frac{\Delta\vec{r}}{\Delta t} = \frac{x_f - x_i}{t_f - t_i}\hat{\imath}. \tag{2.14, 2.15}$$

Additional properties of velocity (Sections 2.8, 2.9)

Concepts When the velocity of an object is constant, its **position-versus-time graph** is a straight line having nonzero slope and its **velocity-versus-time graph** is a horizontal line.

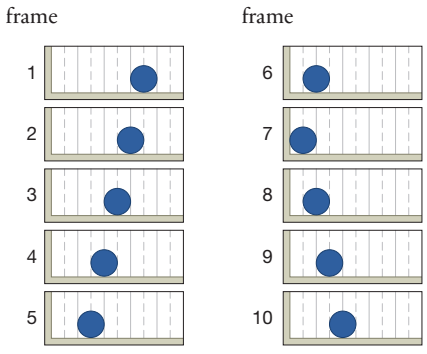
The **instantaneous velocity** of an object is its velocity at any particular instant.

The slope of an object's $x(t)$ curve at a given instant is numerically equal to the x component of the object's velocity at that instant. The area under the object's $v_x(t)$ curve during a time interval is the x component of the object's displacement during that interval.

Quantitative Tools The x component of an object's instantaneous velocity is the derivative of the object's x coordinate with respect to time:

$$v_x \equiv \frac{dx}{dt}. \tag{2.22}$$

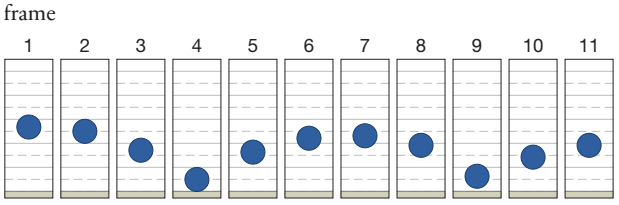
Questions and Problems



For instructor-assigned homework, go to Mastering Physics

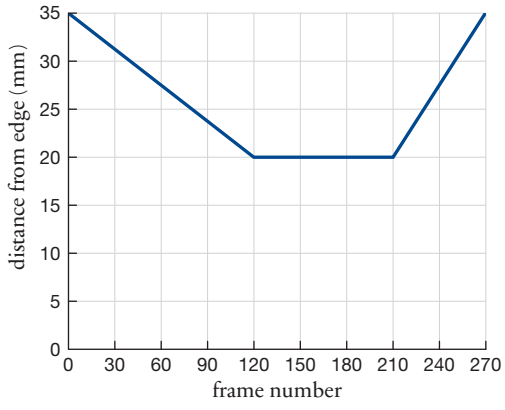
Dots indicate difficulty level of problems: • = *easy*, •• = *intermediate*, ••• = *hard*; CR = *context-rich problem.*

2.1 From reality to model



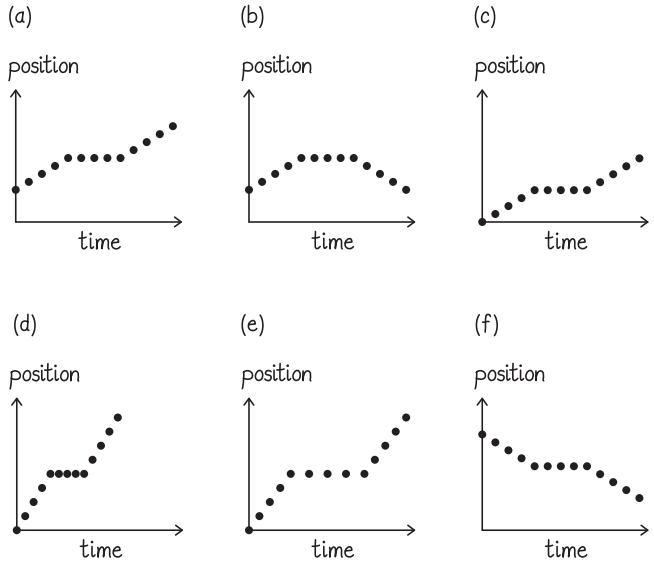
1. What minimum information must be extracted from a video clip of a moving object in order to quantify the object's motion? •
2. The sequence in Figure P2.2 represents a ball rolling into a wall and bouncing off of it. The ball is 10 mm in diameter. Make a graph showing the distance from the leading edge of the ball to the closest part of the wall (using the wall as the origin) as it changes from frame to frame. ••

Figure P2.2



3. The sequence in Figure P2.3 represents a ball that is initially held above the ground. In the first frame the ball is released. In subsequent frames the ball falls, bounces on the ground, rises, and bounces again. The ball is 10 mm in diameter. Make a plot showing the changing height of the ball above the ground. ••

Figure P2.3



4. Figure P2.4 shows a graph of position versus frame number from a video clip of a moving object. Describe this motion from beginning to end, and state any assumptions you make. ••

Figure P2.4

5. Your class observed several different objects in motion along different lines. Figure P2.5 shows some of the graphs other students made of the events. They have labeled the horizontal axis "time" and the vertical axis "position," but they have not marked any points along those axes and have not specified an origin. Which of the graphs could be describing the same motion? ●●

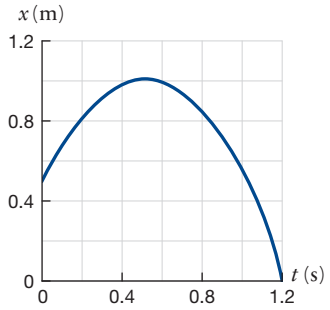


Figure P2.5

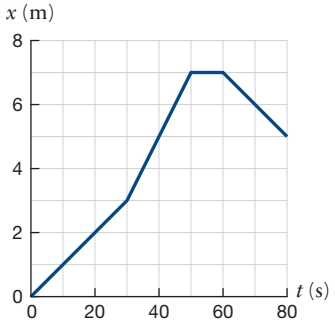
2.2 Position and displacement

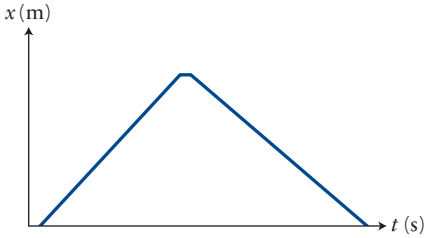


6. A car is initially parked 3.5 m to the left of a fire hydrant. It drives 15.5 m past the hydrant before turning back for 6.0 m and stopping. What is the car's displacement? ●
7. You walk 3.2 km to the supermarket and then back home. What is your distance traveled? What is your displacement? ●
8. You run three times around a 100-m-by-50-m rectangular soccer field and continue for one more length. What is (*a*) the magnitude of your displacement and (*b*) the total distance traveled? ●
9. You are shown a video clip of a dog running in front of a blank wall. The observations are to be plotted using the horizontal and vertical axes labeled with seconds and meters, respectively. How many different graphs of this motion with respect to time could be produced if: (*a*) No additional information is given? (*b*) An origin is given? (*c*) Both the origin and the length of the dog are given? (*d*) An origin, the length of the dog, and the time interval between frames of the video clip are all given? ●●
10. Assume you have a video clip of someone walking from left to right. You draw a position-versus-time graph of the motion and choose your origin to be the left edge of the frame. A friend chooses to take the right edge of the frame as the origin. Both of you choose the positive x direction to be from left to right. (*a*) How would your graphs differ? (*b*) Would the two be equally good representations of reality? ●●
11. Figure P2.11 shows the position measured in meters plotted against time measured in seconds for an object moving in one dimension. For motion between $t = 0$ and $t = 1.2$ s, (*a*) describe the motion of this object. (*b*) What is the distance traveled by this object? (*c*) What is the displacement of the object? ●●

Figure P2.11

12. In the graph in Figure P2.12, determine (*a*) the displacement of the object and (*b*) the distance the object traveled. ●●

Figure P2.12



13. An ant walks along a tight thread that is oriented north to south and can be taken to coincide with the y axis. The ant walks 7 cm south, then turns and walks 2 cm north. It continues another 10 cm north, then 3 cm south, then 12 cm north, then 6 cm south. What is the y component of the ant's displacement in cm? Take the origin to be the ant's starting point. ●●
14. In the foreground of a side-view picture of a table, the legs touch the floor at a point that is 12 mm from the bottom of the picture, and the tabletop is 65 mm from the bottom of the picture. One end of the tabletop is 14 mm from the left edge of the picture, and the other end is 99 mm from the left edge. Estimate the actual length of the tabletop. ●●●

2.3 Representing motion

15. Figure P2.15 shows the position of a swimmer in a race as a function of time. Describe this motion. ●

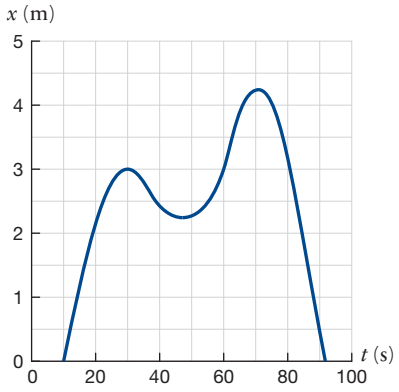


Figure P2.15

16. In the morning, a hiker at the bottom of a mountain heads up the trail toward the top. At the same instant, another hiker at the top of the mountain heads down the same trail toward the bottom. Each hiker arrives at her destination by the end of the day. Explain why, no matter what happens to either hiker along the way (lunch breaks, turnarounds to fetch dropped pocket knives, or changes of pace), they meet on the trail sometime during the day. ●

17. Will interpolation between known data points always give an accurate continuous path? If so, explain why. If not, give a counterexample. •
18. Figure P2.18 shows the motion of an object as a function of time. How long did it take the object to get from the position $x = 2.0$ m to the position $x = 3.0$ m? Is there only one correct answer? ••

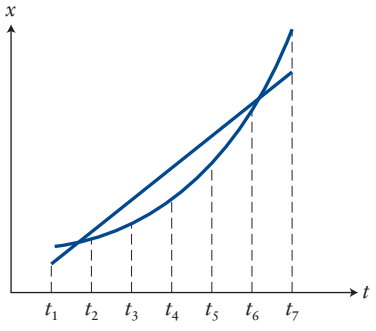
Figure P2.18

19. Figure P2.19 is based on a multiple-flash photographic sequence of a ball rolling from left to right on a soft surface. Plot the ball's position as a function of time. ••

Figure P2.19

20. A remotely controlled helicopter is heading vertically upward when you attempt to land it. Its height is represented by $y(t) = p + qt - rt^2$, where $p = 20.0$ m, $q = 5.0$ m/s, and $r = 5.0$ m/s^2. (*a*) Draw a graph of the motion from $t = 0$ to $t = 2$ s. (*b*) What was the initial position of the helicopter? (*c*) What is the maximum height that it reaches before descending? (*d*) At what time does the helicopter land? ••
21. After a rocket is launched at $t = 0$, its position is given by $x(t) = qt^3$, where q is some positive constant. (*a*) Sketch a graph of the rocket's position as a function of time. (*b*) What is the rocket's displacement during the interval from $t = T$ to $t = 3T$? ••
22. Consider the position function $x(t) = p + qt + rt^2$ for a moving object, with $p = +3.0$ m, $q = +2.0$ m/s, and $r = -5.0$ m/s^2. (*a*) What is the value of $x(t)$ at $t = 0$? (*b*) At what value of t does $x(t)$ have its maximum value? (*c*) What is the value of $x(t)$ at this instant? (*d*) Draw a position-versus-time graph. (*e*) Describe the behavior of an object that is represented by this function. (*f*) How far has the object traveled in these intervals: From $t = 0$ to $t = 0.50$ s? From $t = 0$ to $t = 1.0$ s? From $t = 0.50$ s to $t = 1.0$ s? ••
23. The motion of some object is described by the equation $x(t) = at - b \sin(ct)$, where $a = 1.0$ m/s, $b = 2.0$ m, and $c = 4\pi$ s^{-1}. This motion is being observed by four students, and measurements of the position of this object begin at time $t = 0$. Students A, B, C, and D measure every 1.0 s, 0.5 s, 0.25 s, and 0.1 s, respectively. Draw four graphs of the measurements made by the four different students. Include at least ten data points in each graph. Do the four students agree on the type of motion that is taking place? •••

2.4 Average speed and average velocity



24. In the Midwest, you sometimes see large marks painted on the highway shoulder. How can police patrols flying overhead use these marks to check for speeders? •
25. Calculate the average speed for the runners in the following races: (*a*) 100 m in 9.84 s, (*b*) 200 m in 19.32 s, (*c*) 400 m in 43.29 s, (*d*) 1500 m in 3 min, 27.37 s, (*e*) 10 km in 26 min, 38.08 s, (*f*) marathon (26 mi, 385 yd) in 2 h, 6 min, 50.0 s. •
26. (*a*) Can two cars traveling in opposite directions on a highway have the same speed? (*b*) Can they have the same velocity? •
27. Figure P2.27 is based on a multiple-flash photographic sequence, taken at equal time intervals, of a ball rolling on a smooth surface from right to left. (*a*) Argue that the ball moves with at least two different speeds during the motion represented in the sequence. (*b*) During which part of the motion does the ball have the larger speed? •

Figure P2.27

28. Can the average speed of an object moving in one direction ever be larger than the object's maximum speed? ••
29. Figure P2.29 shows position as a function of time for two cars traveling along the same highway. (*a*) At what instant(s) are the cars next to each other? (*b*) At what instant(s) are they traveling at the same speed? ••

Figure P2.29

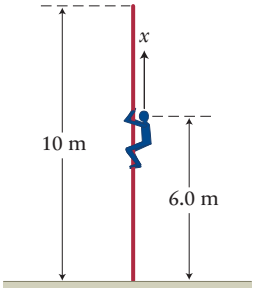
30. Figure P2.30 is based on two multiple-flash photographic sequences of a hockey puck sliding on ice. Sequence *a* was shot at 30 flashes per second, and sequence *b* was shot at 20 flashes per second. Compare the speeds of the puck in the two cases. ••

Figure P2.30

(*a*)

(*b*)

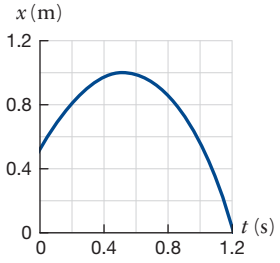
31. A cyclist takes 10 min to ride from point A to point B and then another 10 min to continue on from point B to point C, all along a straight line. If you know that the average speed on the ride from A to B was faster than the average speed on the ride from B to C, what, if anything, can you conclude about the position of point B relative to points A and C? ••
32. In a road rally race, you are told to drive half the trip at 25 m/s and half the trip at 35 m/s. It's not clear from the directions whether this means to drive half the *time* at each speed or drive half the *distance* at each speed. Which would yield the shorter travel time for the entire trip? ••
33. A bicycle racer rides from a starting marker to a turnaround marker at 10.0 m/s. She then rides back along the same route from the turnaround marker to the starting marker at 16.0 m/s. (*a*) What is her average speed for the whole race? (*b*) A friend of yours gets an answer of 13 m/s. What is most likely the source of his error? ••
34. A taxi driver leaves the airport to drop a passenger at his hotel, making the following trips: she drives 7.2 km in 10 min, stops and waits for the passenger at a convenience store for 7 min, drives another 5 km to the hotel in 10 min, where she waits 3 min for the passenger to get off. She then returns to the airport via a different route that is 10 km long in 6 min. (*a*) What is her average speed for the whole trip? (*b*) What is her average velocity? ••
35. You are going to visit your grandparents, who live 500 km away. As you drive on the freeway, your speed is a constant 100 km/h. Half an hour after you leave home, your brother discovers that you forgot your wallet. He jumps into his car and speeds after you. The two of you arrive at your grandparents' house at the same instant. What is your brother's average speed for the trip? ••
36. You and your brother both leave your house at the same instant and drive in separate cars along a straight highway to a nearby lake. After 10 min, you are both 3.0 km from your house. You are now driving at 100 km/h, and you continue at this constant speed; your brother is going faster than this. After another 20 min, your brother arrives at the lake, but you are still 5.0 km away. (*a*) How far is it from your house to the lake? (*b*) What is your brother's average speed for the trip? (*c*) Your brother beats you to the lake by what time interval? •••



2.5 Scalars and vectors

37. You are standing on a sidewalk that runs east-west. Consider these instructions I might give you: (1) Walk 15 steps along the sidewalk and stop. (2) Walk 15 steps westward on the sidewalk and stop. Do my instructions unambiguously determine your final location in each case? •
38. What is the x component of (*a*) $(-1.2\text{ m})\hat{\imath}$, (*b*) $(3.2\text{ m})\hat{\imath}$, and (*c*) $(-1.2\text{ m/s})\hat{\imath}$? •
39. What is the magnitude of (*a*) $(+3\text{ m})\hat{\imath}$, (*b*) $(+3\text{ m/s})\hat{\imath}$, and (*c*) $(-3\text{ m/s})\hat{\imath}$? •
40. Vectors $\vec{A}$ and $\vec{B}$ each have a magnitude of 5 m and point to the left. Vector $\vec{A}$ begins at the origin, while vector $\vec{B}$ begins at a location 8 m to the right of the origin. (*a*) If the positive x axis is pointed to the right, what is the x component of each vector? (*b*) If the positive x axis is pointed to the left, what is the x component of each vector? ••
41. Vector $\vec{A}$ points to the right, as does the positive x axis. (*a*) Express this vector in unit vector notation. (*b*) Now flip $\vec{A}$ to the opposite direction. Express it in unit vector notation. (*c*) Keep the vector in its new direction and flip the x axis so that the positive direction is to the left. Express the vector in unit vector notation. ••

2.6 Position and displacement vectors

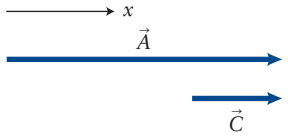


42. Consider three vectors along the x axis, $\vec{A}$, $\vec{B}$, and $\vec{C}$. Let the x components of the three vectors be -2 m, $+3$ m, and -5 m. What are (*a*) $\vec{D} = \vec{A} + \vec{B}$ and (*b*) $\vec{E} = \vec{D} - \vec{C}$? •
43. You stop to rest while climbing a vertical 10-m pole. With the origin at the level of your head and with the positive x direction upward, as shown in Figure P2.43, what are (*a*) the x coordinate of the pole's tip and (*b*) the tip's position vector? •

Figure P2.43

44. The height x above the ground of a vertically launched projectile is given by $x(t) = pt - qt^2$, with $p = 42$ m/s and $q = 4.9\text{ m/s}^2$. (*a*) At what instant is the projectile at a height of 20 m? (*b*) What is the meaning of the two solutions obtained in part *a*? (*c*) Sketch a graph of the x component of the projectile's velocity as a function of time. ••
45. Figure P2.45 shows the x coordinate as a function of time for a moving object. What is the total distance traveled by the object (*a*) between $t = 0$ and $t = 0.45$ s and (*b*) between $t = 0$ and $t = 1.2$ s? What is the displacement of the object (*c*) between $t = 0$ and $t = 0.45$ s and (*d*) between $t = 0$ and $t = 1.2$ s? Which way is the object moving at (*e*) $t = 0.2$ s, (*f*) $t = 0.45$ s, and (*g*) $t = 1.0$ s? ••

Figure P2.45

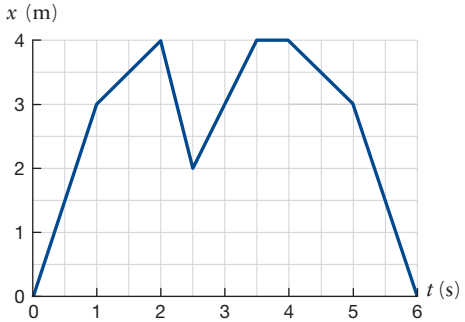


46. Arrange three displacement vectors, of magnitudes 2 m, 5 m, and 7 m, so that their sum is (*a*) $(+10\text{ m})\hat{\imath}$, (*b*) $(-4\text{ m})\hat{\imath}$, and (*c*) 0. ••
47. The direction of vector $\vec{A}$ is opposite the direction of the unit vector $\hat{\imath}$. Vector $\vec{B}$ has half the magnitude of $\vec{A}$, and $\vec{A} - \vec{B}$ is a vector of magnitude $\frac{3}{2}A$. Express $\vec{B}$ in terms of $\vec{A}$. ••
48. You have to deliver some 5.0-kg packages from your home to two locations. You drive for 2.0 h at 25 mi/h due east (call this segment 1 of your trip), then turn around and drive due west for 30 min at 20 mi/h (segment 2). Use a

coordinate system with the positive x axis aimed toward the east and the origin at your home. (*a*) What is your position vector at the instant you reach the end of segment 1? (*b*) What is your position vector at the instant you reach the end of segment 2? (*c*) Calculate your displacement during segment 2. (*d*) Calculate your displacement for the whole trip. (*e*) What is the distance traveled? (*f*) Draw to scale the position vectors you found in parts *a* and *b*. (*g*) Use vector addition to determine the displacement vectors asked for in parts *c* and *d*. Do your results in part *g* agree with the values you calculated in parts *c* and *d*? ●●

49. (*a*) In Figure P2.49, what vector must you add to $\vec{A}$ to get $\vec{C}$? (*b*) What vector must you subtract from $\vec{A}$ to get $\vec{C}$? Sketch your answers on a copy of the figure to confirm your results. ●●

Figure P2.49



2.7 Velocity as a vector

50. After driving due north at 72 km/hr for 2 hours, you stop for 20 min and then head back south at 108 km/hr to reach your starting position. What is your (*a*) average velocity and (*b*) average speed at the end of the trip? ●

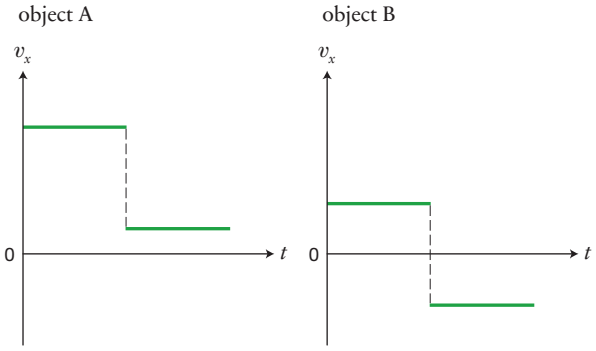
51. For the motion represented in Figure P2.45, calculate (*a*) the object's average velocity between $t = 0$ and $t = 1.2$ s, and (*b*) its average speed during this same time interval. (*c*) Why is the answer to part *a* different from the answer to part *b*? ●●

52. Figure P2.52 is the position-versus-time graph for a moving object. What is the object's average velocity (*a*) between $t = 0$ and $t = 1.0$ s, (*b*) between $t = 0$ and $t = 4.0$ s, and (*c*) between $t = 3.0$ s and $t = 6.0$ s? (*d*) What is its average speed between $t = 3.0$ s and $t = 6.0$ s? (*e*) Draw to scale the velocity vector for the intervals $t = 3.0$ s to $t = 3.5$ s, $t = 3.5$ s to $t = 4.0$ s, $t = 4.0$ s to $t = 5.0$ s, and $t = 5.0$ s to $t = 6.0$ s. (*f*) What is the sum of all the vectors you drew in part *e*? ●●

Figure P2.52

53. You normally drive a 12-h trip at an average speed of 100 km/h. Today you are in a hurry. During the first two-thirds of the distance, you drive at 108 km/h. If the trip still takes 12 h, what is your average speed in the last third of the distance? ●●●

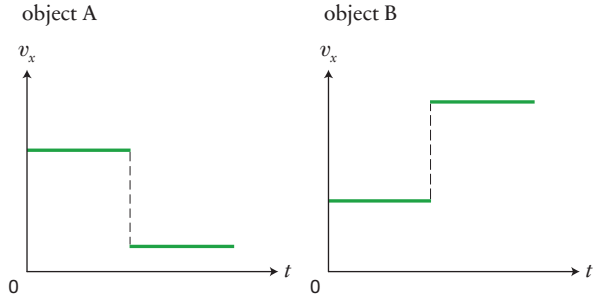
2.8 Motion at constant velocity



54. A cart starts at position $x = -2.073$ m and travels along the x axis with a constant x component of velocity of -4.02 m/s. What is the position of the cart after 0.103 s? ●

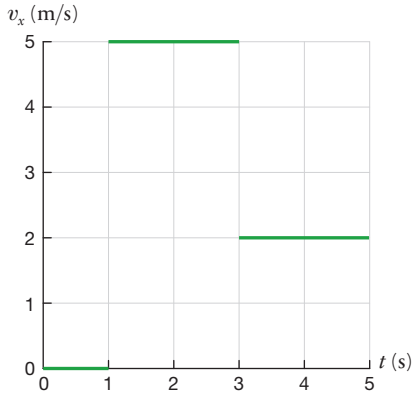
55. A bug on a windowsill walks at 10 mm/s from left to right for 120 mm, slows to 6.0 mm/s and continues rightward for another 3.0 s, stops for 4.0 s, and then walks back to its starting position at 8.0 mm/s. Draw a graph (*a*) of the x coordinate of the bug's displacement as a function of time and (*b*) of the x component of its velocity as a function of time. ●

56. A freight train leaves city A and heads for city B, which is 44 km away, at 12 km/hr. At the same time, a passenger train leaves city B and heads for A. The two trains barely avoid a collision at a station exactly 12 km from city A. At what constant velocity was the passenger train traveling? ●●



57. Figure P2.57 shows the velocity-versus-time graphs for objects A and B moving along an x axis. Which object has the greater displacement over the time interval shown in the graph? ●●

Figure P2.57



58. Figure P2.58 shows the x component of the velocity as a function of time for objects A and B. Which object has the greater displacement over the time interval shown in the graph? ●●

Figure P2.58

59. An object moving along an x axis starts out at $x = -10$ m. Using its velocity-versus-time graph in Figure P2.59, draw a graph of the object's x coordinate as a function of time. ●●

Figure P2.59

60. You and a friend ride bicycles to school. Both of you start at the same instant from your house, you riding at 10 m/s and your friend riding at 15 m/s. During the trip your friend has a flat tire that takes him 12 min to fix. He then continues the trip at the same speed of 15 m/s. If the distance to school is 15 km, which of you gets to school first? ●●

61. You are going on a bicycle ride with a friend. You start 3.0 min ahead of her from her carport, pedal at 5.0 m/s for 10 min, then stop and chat with a neighbor for 5.0 min. As you chat, your friend pedals by, oblivious to you. You notice that she's forgotten to bring the lunch basket you plan to share, and you immediately start to pedal back to her house to get it, now moving at 10 m/s. When you are halfway back, your friend catches up with you, having herself remembered about the basket. (*a*) What was the magnitude of her average velocity for the trip up to that instant? (*b*) What was the magnitude of her average velocity between the instant she passed you and the neighbor and the instant she caught up with you? ●●●

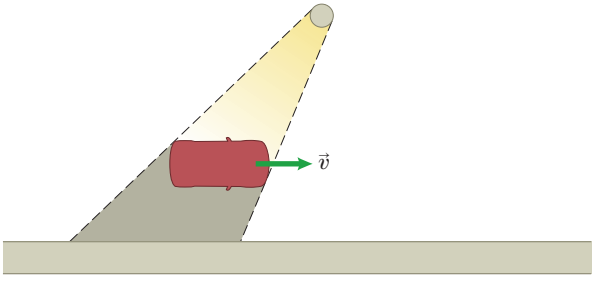
62. A policeman starts giving chase 60 seconds after a stolen car zooms by at 108 km/hr. At what minimum speed should they drive if they have to catch up with the driver before they manage to get onto an expressway 60 km away? ●●●

63. You are jogging eastward at an average speed of 2.0 m/s. Once you are 2.0 km from your home, you turn around and begin jogging westward, back to your house. At one point on your return trip, you look to the north and see a friend. You run northward at a greater speed of 3.0 m/s to catch your friend. After jogging next to each other for a time (at 3.0 m/s), you turn around (southward) and return at 3.0 m/s to your original path, and resume jogging at 2.0 m/s westward. If you return home 40 min after you left, how far north did you run while catching and running with your friend? ●●●

2.9 Instantaneous velocity

64. Which of these quantities depend on the choice of origin in a coordinate system: position, displacement, speed, average velocity, instantaneous velocity? ●

65. An object's position as a function of time is given by $x(t) = -2.0t^2 + 1.0\,t^3$. Calculate (*a*) the object's position and velocity at $t = 2$ s. (*b*) The average velocity between $t = 0$ and $t = 2$ s. ●



66. A mouse runs along a baseboard in your house. The mouse's position as a function of time is given by $x(t) = pt^2 + qt$, with $p = 0.40$ m/s^2 and $q = -1.20$ m/s. Determine the mouse's average velocity and average speed (*a*) between $t = 0$ and $t = 1.0$ s and (*b*) between $t = 1.0$ s and $t = 4.0$ s. ●●

67. Car A is spotted passing car B just east of Westerville at exactly 2:00 p.m. The same two cars are then spotted next to each other just west of Easterville at exactly 3:00 p.m. If car B had a constant velocity of 30 m/s eastward for the whole trip, defend the proposition that car A had to have a velocity of 30 m/s eastward at some instant during that hour. ●●

68. The motion of an electron is given by $x(t) = pt^3 + qt^2 + r$, with $p = -2.0$ m/s^3, $q = +1.0$ m/s^2, and $r = +9.0$ m. Determine its velocity at (*a*) $t = 0$, (*b*) $t = 1.0$ s, (*c*) $t = 2.0$ s, and (*d*) $t = 3.0$ s. ●●

69. The car in Figure P2.69 passes a bright streetlight at constant speed, casting a shadow on a wall on the other side of the street. For simplicity, assume that car and light are at the same height. (*a*) Which is greater: the average speed of the car or the average speed of the shadow's leading edge? (*b*) Is there any instant at which the speed of the shadow's leading edge is the same as the speed of the car? If so, what is the car's position relative to the streetlight at that instant? If not, why not? ●●

Figure P2.69

70. The position of a 6.0-kg shopping cart rolling down a ramp is given by $x(t) = p + qt^2$, with $p = +1.50$ m and $q = +2.00$ m/s^2. What is the x component of the cart's average velocity (*a*) between $t = 2.00$ s and $t = 3.00$ s, (*b*) between $t = 2.00$ s and $t = 2.10$ s, and (*c*) between $t = 2.00$ s and $t = 2.01$ s? (*d*) Compute the limit of the average velocity between $t_i = 2.00$ s and $t_f = 2.00\text{ s} + \Delta t$ as Δt approaches zero. (*e*) Show that your result agrees with what is expected by taking the time derivative of position. ●●●

Additional Problems

71. You leave Fort Worth, Texas, at 2:38 p.m. and arrive in Dallas at 3:23 p.m., covering a distance of 58 km. What is your average speed (*a*) in meters per second and (*b*) in miles per hour? •
72. In a footrace between two runners, is it possible for the second-place finisher to have a greater speed at the finish line than the winner? •
73. You wish to describe the position of the base of the pole in Figure P2.43 using the indicated coordinate system. What are (*a*) the position coordinate of the base, (*b*) the position vector of the base, and (*c*) the magnitude of that vector? •
74. Runners P, Q, and R run a 5-km race in 15, 20, and 25 min, respectively, each at a constant speed. When runner Q crosses the 1-km mark, what is the distance, to the nearest meter, between runners P and R? Assume that times and distances are correct to at least four significant digits. ••
75. Runners A, B, and C run a 100-m race, each at a constant speed. Runner A takes first place, beating runner B by 10 m. Runner B takes second place, beating runner C by 10 m. By what time interval does runner A beat runner C? (Express your answer in terms of runner A's total time.) ••
76. At $t = 0$, car A passes a milepost at constant speed v_A. Car B passes the same milepost at constant speed $v_B > v_A$ after a time interval Δt has elapsed. (*a*) In terms of v_A, v_B, and Δt, at what instant does car B catch up to car A? (*b*) How far past the milepost does this happen? ••
77. You and your friend are running at a long racetrack. You pass the starting line while running at a constant 4.0 m/s. Fifteen seconds later, your friend passes the starting line while running at 6.0 m/s in the same direction, and at the same instant you increase your speed to 5.0 m/s. (*a*) How long does it take for your friend to catch up with you? (*b*) How far are the two of you from the starting line when your friend catches up with you? ••
78. You drive an old car on a straight, level highway at 45 mi/h for 10 mi, and then the car stalls. You leave the car and, continuing in the direction in which you were driving, walk to a friend's house 2.0 mi away, arriving 40 min after you begin walking. What is your average speed during the whole trip? ••
79. An object's position is represented by $x(t) = 2.0\,t^{\frac{3}{2}}$. Compare the instantaneous velocity of the object at $t = 4$ s to its average velocity between $t = 0$ and $t = 4$ s. ••
80. The following equations give the x component of the position for four objects as functions of time:

    object 1: $x(t) = a$, where $a = 5$ m

    object 2: $x(t) = bt + c$, where $b = +4$ m/s and $c = -1$ m

    object 3: $x(t) = et^2 + ft$, where $e = +5$ m/s^2 and $f = -9$ m/s

    object 4: $x(t) = gt^2 + h$, where $g = -3$ m/s^2 and $h = +12$ m.

    (*a*) Which objects have a velocity that changes with time? (*b*) Which object is at the origin at the earliest instant, and what is that instant? (*c*) What is that object's velocity 1 s after the instant you calculated in part *b*? ••
81. A furniture mover is lifting a small safe by pulling on a rope threaded through the pulley system shown in Figure P2.81. (*a*) What is the ratio of the vertical distance the safe moves to the length of the rope pulled by the mover? (*b*) What is the ratio of the speed of the safe to the speed of the segment of rope pulled by the mover? ••

Figure P2.81

82. Two steamrollers begin 100 m apart and head toward each other, each at a constant speed of 1.00 m/s. At the same instant, a fly that travels at a constant speed of 2.20 m/s starts from the front roller of the southbound steamroller and flies to the front roller of the northbound one, then turns around and flies to the front roller of the southbound once again, and continues in this way until it is crushed between the steamrollers in a collision. What distance does the fly travel? ••
83. Consider a 2.0-kg object that moves along the x axis according to the expression $x(t) = ct^3$, where $c = +0.120$ m/s^3. (*a*) Determine the x component of the object's average velocity during the interval from $t_i = 0.500$ s to $t_f = 1.50$ s. (*b*) Repeat for the interval from $t_i = 0.950$ s to $t_f = 1.05$ s. (*c*) Show that your results approach the x component of the velocity at $t = 1.00$ s if you continue to reduce the interval by factors of 10. Use all significant digits provided by your calculator at each step. ••
84. The position of a yo-yo as a function of time is given by $x(t) = A\cos(pt + q)$, where $A = 0.60$ m, $p = \frac{1}{2}\pi$ s^{-1}, and $q = \frac{1}{2}\pi$. (*a*) Plot this function at 17 equally spaced instants from $t = 0$ to $t = 8.0$ s. (*b*) At what instants is the velocity zero? (*c*) Plot the x component of the velocity as a function of time over the time interval from $t = 0$ to $t = 8$ s. •••
85. Zeno, a Greek philosopher and mathematician, was famous for his paradoxes, one of which can be paraphrased as follows: A runner has a race of length d to run. After an elapsed time interval Δt after the start, he is a distance $\frac{1}{2}d$ from the finish line. After an additional time interval of $\frac{1}{2}\Delta t$ (elapsed time is $\Delta t + \frac{1}{2}\Delta t$), he has traveled a distance of $\frac{3}{4}d$. He then is a distance $\frac{1}{4}d$ from the finish line. At elapsed time $\Delta t + \frac{1}{2}\Delta t + \frac{1}{4}\Delta t$, he is a distance $\frac{1}{8}d$ from the finish line, and so on. This description of the motion is an infinite series of smaller and smaller displacements. The paradox is that this analysis suggests that the runner will never make it to the finish line, even though we know he does. (*a*) What is the runner's speed? (*b*) What time interval is needed for the trip? (*c*) Describe the resolution to this seeming paradox. •••

86. Four traffic lights on a stretch of road are spaced 300 m apart. There is a 10-s lag time between successive green lights: The second light turns green 10 s after the first light turns green, the third light turns green 10 s after the second light does (and thus 20 s after the first light turns green), and so on. Each light stays green for 15 s. Having watched this sequence for some time, you understand that there should be one best constant speed to drive to make all four green lights. You do not want to be delayed, but you are a cautious driver and want to drive as slowly as you can but still make it through all the lights on a single cycle. ●●● CR

87. Hare and Tortoise of Aesop's fable fame are having a rematch, a mile-long race. Hare has planned more carefully this time. Five minutes into the race, he figures he can take a 40-min nap and still win easily because it takes him only 10 min to cover 1 mi and because he thinks that Tortoise's top speed is 1.0 mi/h. However, Tortoise has been working out, and as he passes napping Hare, he suddenly increases his speed to $\frac{5}{3}$ mi/h.When Hare wakes up, he sees Tortoise way ahead and runs at full speed to try to catch up. ●●● CR

88. Two friends are running a 1000-m race. Jim gets a head start on Jack by starting earlier. How much earlier should Jim start to win the race if he can only run at 6.8 m/s while Jack can easily run at 7 m/s? ●●●

89. You are on planet Dither, whose inhabitants often change their minds on how to choose a reference axis. At time $t = 0$, while standing 2.0 m to the left of the origin of a reference axis for which the positive x direction points to the left, you launch a toy car that moves with increasing speed to the right. The car's x coordinate (x component of the position) is given by $x(t) = p + qt + rt^2$, where $p = +2.0$ m, $q = -3.0$ m/s, and $r = -4.0$ m/s^2. (*a*) What is the equation of the car's x coordinate if the reference axis is flipped so that the positive direction points to the right? (*b*) What is the equation of the car's x coordinate if the axis is kept in its original orientation (leftward is the positive direction) but the origin is moved to where you are standing? (*c*) Draw a position-versus-time graph for each of the three combinations of axis direction and origin location. (*d*) What is the x component of the car's displacement at $t = 4.0$ s in each of these three axis/origin combinations? (*e*) What is the x component of the car's velocity at this instant in each combination? (*f*) Explain why there is no physical difference in the answers to parts *d* and *e* even though some of the mathematical expressions you get look different from one another. ●●●

90. Your dream job as a 12-year-old was to sit at a computer at NASA mission control and guide the motion of the Mars rover across the Martian surface 2.0×10^8 km away. Communication signals to steer the rover travel at the speed of light between Earth and Mars, and the rover's top speed is 2.0 m/min. In your dream, your job was to make sure, based on television images beamed back from the craft, that the rover does not run off a Martian cliff. The shift supervisor recommended that your first task be to determine how far ahead in the rover's field of view you have to watch out for obstacles in order to avoid a disaster. ●●● CR

91. You are a driver for Ace Mining Company. The boss insists that, every hour on the hour, a loaded truck leaves the mine at 90.0 km/h, carrying ore to a mill 630 km away. She also insists that an empty truck traveling at 105 km/h leaves the mill every hour on the half hour to return to the mine. One day you begin to count the empty trucks that you encounter, per hour, on your trip to the mill. The next day you decide that loaded trucks are more important, counted on your return trip. ●●● CR

Acceleration

CONCEPTS

3.1 Changes in velocity
3.2 Acceleration due to gravity
3.3 Projectile motion
3.4 Motion diagrams

QUANTITATIVE TOOLS

3.5 Motion with constant acceleration
3.6 Free-fall equations
3.7 Inclined planes
3.8 Instantaneous acceleration

In Section 2.8 we considered objects moving at constant velocity—unchanging speed and unchanging direction. Most motions, however, are not at constant velocity because things speed up and slow down and change direction all the time. Any change in velocity is caused by *acceleration,* the subject of this chapter.

3.1 Changes in velocity

Consider a car at rest at a traffic light. The light turns green, and the driver puts the car in motion. As long as the car's velocity is changing, the car is *accelerating:*

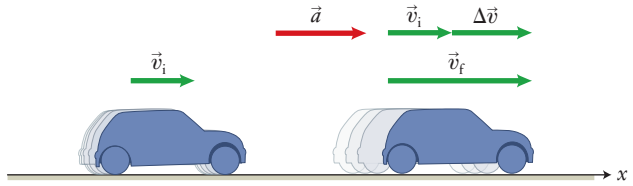
If an object's velocity is changing, the object is accelerating.

An object's velocity can change quickly or slowly: A sports car takes off much more quickly than a heavily loaded truck. Starting from rest, a sports car can reach a speed of 30 m/s in as little as 5 s; a truck might take minutes to reach the same speed. The difference between the two motions is the *rate* at which the speeds change. For example, if a sports car's speed increases from 0 to 10 m/s in 2.5 s, the rate at which the speed changes is $(10\ \text{m/s} - 0)/(2.5\ \text{s}) = 4.0\ \text{m/s}^2$. This rate, which is typically greater for a sports car than for a truck, is the magnitude of a quantity we call *acceleration*. Like velocity, acceleration is a vector, and so we need not only a magnitude but also a direction to specify it completely. We represent acceleration by the symbol $\vec{a}$.

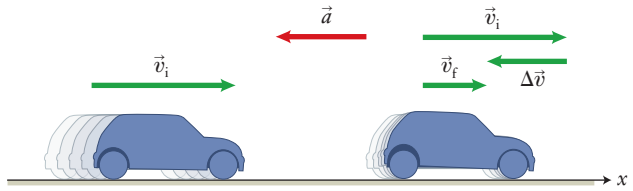
For now, let's return to the example of the sports car and choose the x axis along its direction of travel. The rate at which the x component of the car's velocity changes is called the x component of its **average acceleration:**

The x component of the average acceleration of an object is the change in the x component of the velocity divided by the time interval during which this change took place.

I deliberately use the word *average* here because nothing prevents the x component of the car's velocity from increasing at different rates. For example, the x component of its velocity could increase from 0 to +5.0 m/s in 1.0 s, and then from +5.0 m/s to +10 m/s in 1.5 s.

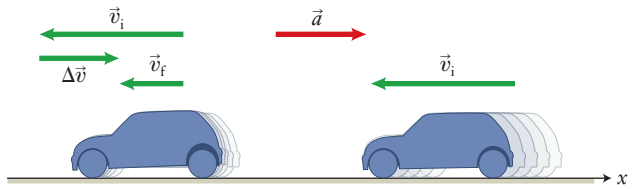


The SI unit of acceleration, m/s^2 (meters per second squared), is a shorthand way of writing (m/s)/s (meters per second, per second). If something accelerates at $+1\ \text{m/s}^2$, the x component of its velocity increases by +1 m/s each second. One of the units of time in the s^2 comes from the change in velocity; the other comes from the time interval during which this change occurs.



3.1 The x component of a car's velocity increases from 0 to +5.0 m/s in 1.0 s, and then from +5.0 m/s to +10 m/s in the next 2.0 s. What is the x component of its average acceleration (*a*) during the first second, (*b*) during the last 2 seconds, and (*c*) during the entire 3.0-s interval?

Figure 3.1 The direction of the car's acceleration depends on the direction of the x axis and on whether the car is speeding up or slowing down.



(*a*) Car speeds up in positive x direction

(*b*) Car slows down in positive x direction

(*c*) Car slows down in negative x direction

To see how the direction of acceleration relates to the motion, consider **Figure 3.1**. In Figure 3.1*a* a car traveling in the positive x direction (which means that its velocity points in the positive x direction) speeds up. The magnitude of the car's final velocity $\vec{v}_f$ is greater than the magnitude of the car's initial velocity $\vec{v}_i$, and so the change in the car's velocity $\Delta\vec{v} \equiv \vec{v}_f - \vec{v}_i$, which points from the tip of $\vec{v}_i$ to the tip of $\vec{v}_f$ (see Figure 2.27*a*), is in the positive x direction. By definition the acceleration $\vec{a}$ always points in the same direction as $\Delta\vec{v}$, and so here $\vec{a}$ points in the positive x direction. Consequently, the x component of the car's acceleration is positive: $a_x > 0$.

The car in Figure 3.1*b* also travels in the positive x direction, but this car slows down, and so $\Delta\vec{v}$ now points in the negative x direction—opposite the velocity vector. The acceleration vector, again pointing in the same direction as $\Delta\vec{v}$, also points in the negative x direction, giving a negative x component of the car's acceleration: $a_x < 0$.

Because its velocity is decreasing, you may be tempted to say that the car in Figure 3.1*b* is "decelerating"—an everyday expression used to indicate that something is slowing down. In physics, however, the word *deceleration* is not necessary and therefore best avoided; *acceleration* refers to *any* change in velocity, regardless of whether the object is speeding up or slowing down.

CONCEPTS

Figure 3.1*c* shows a surprising fact: A positive a_x does not have to mean speeding up. As you can see from the figure, the car slows down while traveling in the negative x direction. Because of the direction of travel, the car's velocity $\vec{v}$ now points in the negative x direction. The vector $\Delta\vec{v}$, however, points in the positive x direction (still from the tip of $\vec{v}_i$ to the tip of $\vec{v}_f$). The acceleration therefore also points in the positive x direction, and so the x component of the car's acceleration is *positive* even though the car slows down!

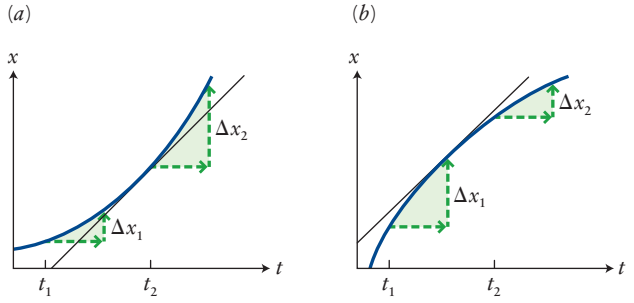
Whenever an object's velocity and acceleration vectors point in the same direction, the object speeds up. When they point in opposite directions, the object slows down.

3.2 The x component of the velocity of a car changes from -10 m/s to -2.0 m/s in 10 s. (*a*) Is the car traveling in the positive or negative x direction? (*b*) Does $\Delta\vec{v}$ point in the positive or negative x direction? (*c*) Is the x component of the car's acceleration positive or negative? (*d*) Is the car speeding up or slowing down?

When working with objects traveling in the negative x direction, don't confuse "positive x component of acceleration" with "speeding up." The x component of velocity in Figure 3.1*c*, for example, is increasing (it gets less negative), and so a_x is positive even though the car is slowing down. Something speeds up when the *magnitude* of its velocity (which, remember from Chapter 2, is called its *speed*) increases, regardless of which way the object is moving. Whether or not the x component of an object's acceleration is positive, however, depends on the direction in which the object is moving.

As mentioned in Section 2.8, the $x(t)$ curve for an object moving at constant velocity is a straight line (see Figure 2.29*a*). When the velocity is not constant, the $x(t)$ curve is not straight. In **Figure 3.2*a***, the x component of displacement Δx_2 during a certain time interval Δt beginning at t_2 is larger than the x component of displacement Δx_1 during the same time interval beginning at t_1. This means that the x component of the object's velocity is increasing. In Figure 3.2*b*, where the

Figure 3.2 Position-versus-time graphs for objects accelerating along the positive x axis.



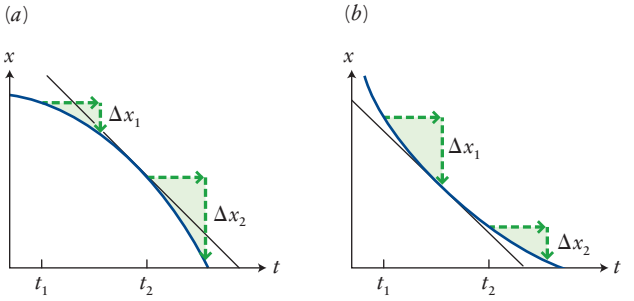


Figure 3.3 Position-versus-time graphs for objects accelerating along the positive x axis.

$x(t)$ curve bends downward, the x component of displacement Δx_2 beginning at t_2 is smaller than the x component of displacement Δx_1 beginning at t_1, telling us that the x component of the velocity is decreasing.

3.3 (*a*) In **Figure 3.3**, are the x components of the velocity represented by the $x(t)$ curves positive or negative? (*b*) Are the speeds increasing or decreasing? (*c*) Are the x components of $\Delta\vec{v}$ positive or negative? (*d*) Are the x components of the acceleration positive or negative?

If you answered Checkpoint 3.3 correctly, you are to be congratulated. Getting this right the first time around is not easy.

An interesting point to note is the following: In Figures 3.2*a* and 3.3*b*, the curves lie above the tangent to any point on them (they are said to *curve up* because they bend upward from the tangent), and the corresponding x components of acceleration are positive. The curves in Figures 3.2*b* and 3.3*a* lie below the tangent to any point; they are said to *curve down*, and the corresponding x components of acceleration are negative. So the sign of the x component of the acceleration is directly related to the curvature of an $x(t)$ curve:

The curvature of an $x(t)$ curve is a measure of the x component of acceleration. An upward curvature corresponds to a positive x component of acceleration. A downward curvature corresponds to a negative x component of acceleration.

3.4 (*a*) A car is speeding up in the negative x direction. In what direction do $\vec{a}$ and $\vec{v}$ point? (*b*) To which of the four graphs in Figures 3.2 and 3.3 does the situation represented in Figure 3.1*c* correspond?

3.2 Acceleration due to gravity

As an example of accelerated motion, think of an object falling in a straight line toward Earth's surface. We attribute the falling to *gravity* and say that there is a gravitational attraction between Earth and the object. Even though we don't know the ultimate cause of gravitational attraction, we can describe its effects.

CONCEPTS

Figure 3.4 Multiple-flash picture of a ball falling. The time interval between successive flashes is 0.05 s. Note how the distance traveled increases from one time interval to the next.

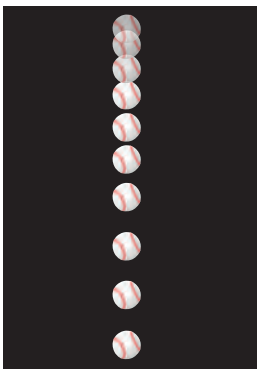

Figure 3.4 shows the positions of a falling ball recorded at equal time intervals of 0.05 s. Note how the spacing between successive positions increases as the ball drops. The picture tells us that the ball covers increasingly large distances in successive equal time intervals, and so we know that its speed increases as it falls. In other words, the ball accelerates. Two questions come to mind: *What is the magnitude of the acceleration as an object falls*? and *Does the acceleration depend on the physical characteristics of the object*?

Let us begin with the second question. If you drop a feather and a stone from the same height, there is no denying that the stone hits the ground first. This observation suggests that heavier objects fall faster than lighter ones—a common thought until the Italian mathematician, astronomer, and physicist Galileo Galilei (1564–1642) began to question its validity. Galileo observed that there is no difference between the amount of time taken by two stones to fall the same distance, even if the difference in weight is substantial and the stones are dropped from a considerable height. He argued that any observed difference in the amount of time it takes two objects to fall is a consequence of air resistance, which has a tendency to slow down lighter objects more than heavier ones.

3.5 Hold a book and a sheet of paper, cut to the same size as the book, side by side 1 m above the floor. Hold the paper parallel to the floor and the book with its covers parallel to the floor, and release them at the same instant. Which hits the floor first? Now put the paper on top of the book and repeat the experiment. What do you notice?

Figure 3.5 shows the effect of air resistance on a falling stone and a falling feather. One stone and one feather are dropped inside a glass tube from which the air has been pumped out. An identical stone and feather are released in air next to the tube. Figure 3.5*a* shows the situation at the simultaneous release of both pairs;

Figure 3.5 (*a*) Feathers and stones released from a certain height inside and outside an evacuated tube. (*b*) In air, the feather soon lags behind the stone; in vacuum, the two fall at the same speed.

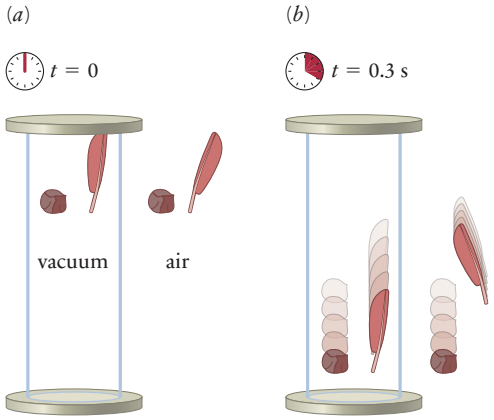

Figure 3.5*b* shows the situation 0.3 s after release. In air, the feather lags behind the stone. Inside the tube, however, both the stone and the feather fall the same distance. In vacuum, in other words, the feather "falls like a rock." Repeating this experiment with many different objects, we discover that, in the absence of air resistance, the acceleration due to gravity does not depend on the physical characteristics of the falling object.

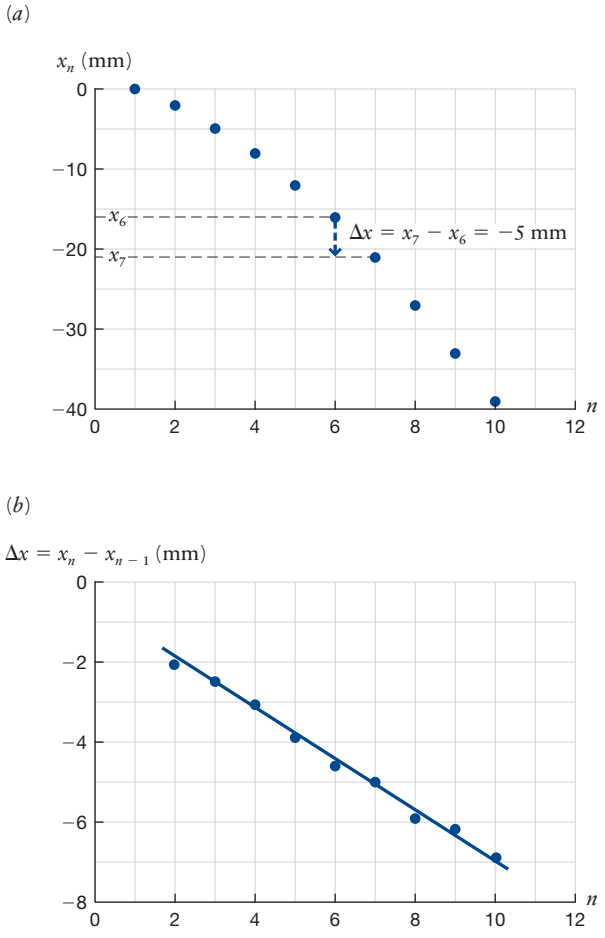
The motion of objects moving under the influence of gravity only is called **free fall.** The feather inside the evacuated tube is in free fall, but the feather outside the tube is not because its motion is influenced not just by gravity but by air resistance, too.

Notice that the effect of air resistance on the stone outside the tube is hardly noticeable—it falls just as fast as the stone in vacuum. This is true for many objects as long as they are not too light and as long as they are not dropped from too great a height. So, unless you drop a light object from any height or a heavy one from the top of the Eiffel Tower, you can ignore air resistance and consider all dropped objects to be in free fall.



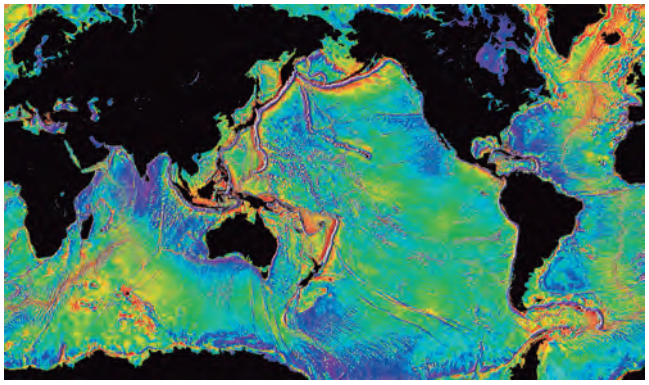
Let us now turn to the first question we posed earlier: What is the magnitude of the acceleration due to gravity? In **Figure 3.6*a*** I have plotted the positions of the ball (technically, its image) in Figure 3.4; for each image of the ball, I measured the position from the center of the ball to the center of the topmost ball. Figure 3.6*b* shows the x component of the displacement between successive exposures; note how the magnitude of the displacement increases from one exposure to the next, telling us that the ball is accelerating.

3.6 What does Figure 3.6*b* tell you about the velocity of the ball from one exposure to the next?

Checkpoint 3.6 is tricky not because I wanted to mislead you but because it is important to see the difference

CONCEPTS

Figure 3.6 (*a*) Position-versus-time graph of the freely falling ball (image) in Figure 3.4 for successive flashes $n = 1, 2, \ldots, 10$. (*b*) The change in the ball's x coordinate during the 10 exposures.



between plotting position versus time and plotting displacement (*change* in position) versus time.*

The ball's position at a given instant is simply its distance from the starting position, which is what Figure 3.6*a* shows. What Figure 3.6*b* shows is the x component of the *displacement* $\Delta x = x_f - x_i$ from one exposure to the next. Because the motion is not at constant velocity, the displacement changes from one exposure to the next. I include this graph to show the following remarkable fact: The data points lie on a straight line, which means that the magnitude of the displacement increases at a constant rate. Because velocity is proportional to displacement, this graph tells us that the velocity of the ball increases at a constant rate; in other words, the ball's acceleration is constant. So, for an object in free fall, the acceleration remains *constant* throughout the object's fall toward Earth.

*If you skipped the checkpoint, please do it now before I give you the answers. When you read a thriller, do you skip to the last page to find out how it ends? If you are puzzled by my questions, don't be discouraged and don't give up too soon. I wrote these questions precisely to arouse your curiosity. Discovering the answers to them is part of the learning process. Once you figure out the answers, you are unlikely to forget them. Taking the time to answer each checkpoint gives you something of lasting value. And if you like challenges, figuring out these checkpoints is without any doubt the easiest and most enjoyable way to learn physics. So take my advice to heart: Don't spoil the puzzle. You can do it—and you won't regret it!

Figure 3.7 Gravity map of Earth's oceans compiled from Seasat satellite data. The coloration shows variations in the value of the acceleration due to gravity of a few tenths of a percent.

Experiments show that, near Earth's surface in the absence of air resistance, the magnitude of the acceleration of all objects due to gravity for all objects in free fall is 9.8 m/s^2.

In the absence of air resistance, the magnitude of the acceleration of all falling objects is 9.8 m/s^2, and consequently the amount of time it takes to fall from a certain height is the same for all falling objects.

So, each second an object falls, its speed increases by about 10 m/s. After 1 s, an object released from rest near Earth's surface has a speed of about 10 m/s. After 2 s, its speed is about 20 m/s, and so on. The value of the acceleration due to gravity varies a few tenths of a percent over Earth's surface (**Figure 3.7**).

CONCEPTS

3.7 (*a*) Does the speed of a falling object increase or decrease? (*b*) If the positive x axis points up, does v_x increase or decrease as the object falls? (*c*) Is the x component of the acceleration positive or negative?

3.3 Projectile motion

So far we have considered only the motion of freely falling objects released from rest. Let us now see what happens when we *launch* an object upward, so that it is already moving when we release it. An object that is launched but not self-propelled is called a *projectile,* and its motion is called **projectile motion.** The path the object follows is called its **trajectory.** The motion of an object in free fall is a special case of projectile motion.

Consider a ball launched straight up, as in **Figure 3.8*a***. The ball first moves up and then reverses its direction of travel; its trajectory therefore is a straight line. Figure 3.8*b* shows a film or video clip of the motion of the ball; between frames 1 and 9 the ball moves vertically upward, and between frames 9 and 16 it moves vertically downward.

Figure 3.8 A ball launched vertically upward travels to its highest position and then retraces its path; the vertical "ruler" in each frame allows us to determine the position of the ball as a function of time.

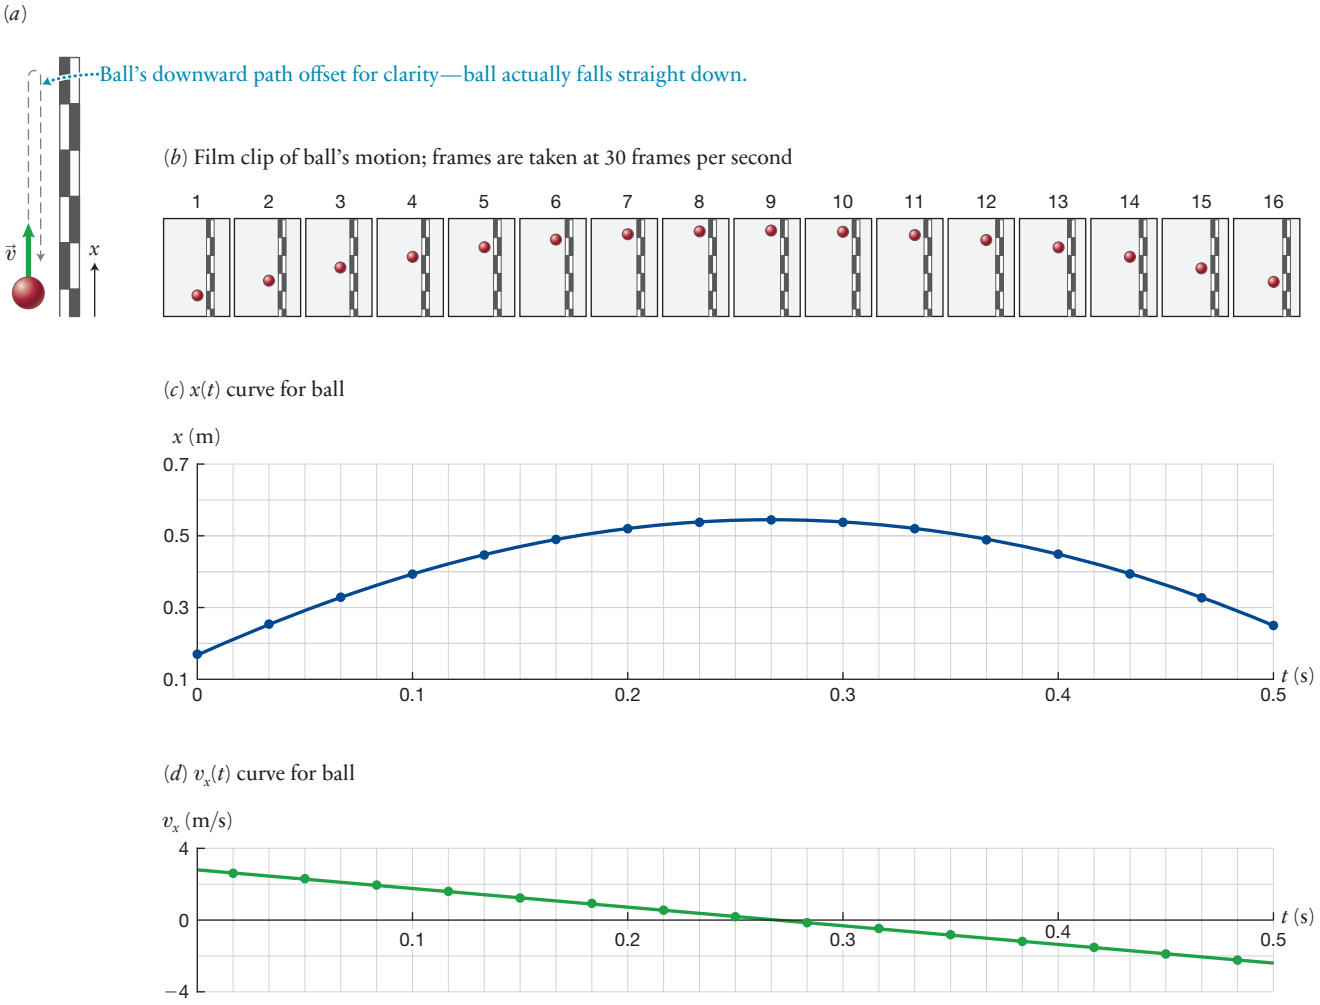


Figure 3.8*c* shows the ball's position for each frame in the clip, and in Figure 3.8*d* I have plotted the ball's average velocity in each frame, obtained by dividing the displacement from one frame to the next by the 33-ms time interval between frames. As you can see, the velocity gets smaller and smaller as the ball nears the top of the trajectory. The ball then reverses direction, and so its velocity becomes negative. Beyond frame 9, the ball's speed—the magnitude of its velocity—increases again.

Because the ball slows down as it moves upward, its acceleration $\vec{a}$ and velocity $\vec{v}$ must point in opposite directions. Thus, because the velocity points upward, the acceleration points downward while the ball is moving upward. As the ball moves downward, it speeds up, and so now its acceleration and velocity both point downward. In other words, the ball's acceleration points downward both on the way up and on the way down.

Figure 3.8*d* shows that the ball's velocity changes *linearly*—it changes by equal amounts in equal time intervals—and so the acceleration is constant. The slope of the straight line in Figure 3.8*d* is about $-10\ \text{m/s}^2$, which is the acceleration due to gravity. Therefore we see that, both on the way up and on the way down, the acceleration of a projectile is equal *both in magnitude and in direction* to that of a freely falling object.

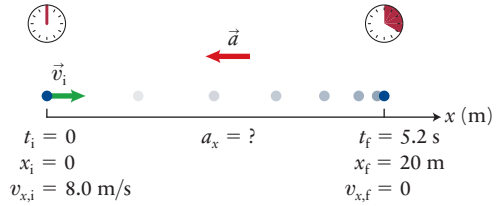
If you throw a stone vertically upward and it has a velocity of +20 m/s right after leaving your hand, it slows down to +10 m/s after 1 s and reverses direction after 2 s. After 3 s, the stone is moving downward with a velocity of −10 m/s. Each second, gravity reduces the stone's velocity by another 10 m/s regardless of whether the stone is moving upward, moving downward, or instantaneously has zero velocity at the top. If you throw the stone harder, it leaves your hand with a higher speed, but once it leaves your hand, its motion is determined *solely* by gravity! In other words:

If an object is launched upward, the launch affects only the initial velocity. Once the object is released, the rest of its motion is determined by gravity alone (free fall).

3.8 Imagine throwing a ball downward so that it has an initial speed of 10 m/s. What is its speed 1 s after you release it? 2 s after?

CONCEPTS

What happens at the very top of the trajectory of a ball launched upward? Because the x component of the ball's velocity goes from positive to negative at the top, there must be an instant at which the x component of the velocity is zero. The x component of the acceleration, however, is *not* zero at the top. To see why, consider the motion over a small time interval Δt during which the ball reaches its highest position. Just before the ball reaches the top, its velocity $\vec{v}$ points upward; just after the ball reaches the top, the velocity points downward. The vector $\Delta\vec{v}$ therefore points downward, and so does the acceleration $\vec{a}$. This holds true regardless of the size of the time interval: As we make Δt smaller, Δv_x becomes smaller, too, but the ratio $\Delta v_x/\Delta t$ remains equal to the slope of the $v_x(t)$ curve in Figure 3.8*d*. So the acceleration of the ball is the same *everywhere*: on the way up, on the way down, and at the top.



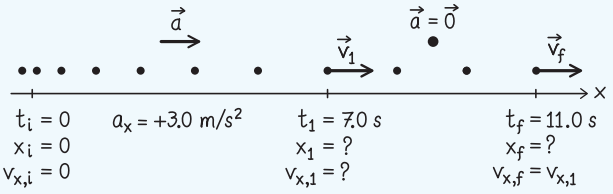
If it seems odd that the acceleration at the top is nonzero, remember that the velocity must change there from up to down, and any change in velocity—be it a change in magnitude or a change in direction—means a nonzero acceleration. That the x component of the velocity is zero doesn't matter: The x component of the velocity doesn't remain zero for any finite time interval; it is only *instantaneously* zero, and in order for it to change, there must be an acceleration. Note, also, that even though the x component of the velocity is instantaneously zero, it is not correct to say that the ball is "instantaneously at rest"; *at rest* means that the position of the ball is not changing (see Section 2.1), which is not the case at any position along the ball's trajectory, including the very top.

3.4 Motion diagrams

To help us visualize the motion of an object described in a problem, we make a **motion diagram** representing the position of the moving object at equally spaced time intervals. Motion diagrams look very similar to the multiple-flash picture shown in Figure 3.4 and provide a visual overview of all you know about the motion. The procedure for making such diagrams is explained in the box on page 93.

Suppose a bicycle rider going 8.0 m/s applies the brake and slows down to a stop over a distance of 20 m in 5.2 s. The motion diagram in **Figure 3.9** shows that same information in graphical form. Note how the diagram shows all we know about the motion: the initial velocity, the distance it takes to come to a stop, and the time interval over which the stopping takes place. The spacing of the dots shows that the object of interest is slowing down. The question mark shows what information is missing. Making such a diagram helps you visualize the problem, organize the information given, and choose a convenient reference axis.

Figure 3.9 Motion diagram for bicycle rider slowing down to a stop.



Nearly all problems in physics—and motion diagrams in particular—involve considering changes that occur over a certain time interval. Throughout this book we shall use clocks as in Figure 3.9 to mark the beginning and end of the time interval of interest. An important part of any physics problem is to record the parameters that characterize the situation under consideration at the beginning and end of that time interval (the *initial* and *final conditions*). When drawing motion diagrams, for example, we record an object's initial and final positions as well as its initial and final velocities. We begin applying this procedure in the next two examples.

EXERCISE 3.1 Accelerating car

Starting from rest, a car accelerates for 7.0 s at 3.0 m/s^2 and then travels at constant velocity for another 4.0 s. Make a motion diagram representing this motion.

SOLUTION The motion consists of two parts: constant acceleration during the first 7.0 s and constant velocity (zero acceleration) during the last 4.0 s. In my motion diagram (**Figure 3.10**) I show both parts of the motion: On the left the spacing between the dots increases to show the acceleration; on the right the spacing is constant to show motion at constant velocity.

Figure 3.10

I chose a positive x axis pointing in the direction of travel and with the origin at the car's starting position. The initial conditions are $t_i = 0$, $x_i = 0$, and $v_{x,i} = 0$.

Before specifying the final conditions, I must consider the instant where the car stops accelerating. This instant, which I denote by t_1, occurs 7.0 s after the car begins to accelerate. Neither the car's position nor its velocity at that instant is known, so I denote these values by question marks in the diagram.

The car then moves at constant velocity for 4.0 s, so the final conditions are $t_f = 11.0$ s, $x_f = ?$, and $v_{x,f} = v_{x,1}$. I complete the diagram by indicating that the x component of the car's acceleration is +3.0 m/s^2 between t_i and t_1 and zero between t_1 and t_f. ✔

✔ The checkmark shows that I carried out the following checks: Vectors and scalars used appropriately; Everything answered; No unknowns left; Units correct; Significant digits justified.

CONCEPTS

PROCEDURE: Analyzing motion using motion diagrams

When you solve motion problems, it is important to begin by making a diagram that summarizes what you know about the motion.

1. Use dots to represent the moving object at equally spaced time intervals. If the object moves at constant speed, the dots are evenly spaced; if the object speeds up, the spacing between the dots increases; if the object slows down, the spacing decreases.
2. Choose an x (position) axis that is convenient for the problem. Most often this is an axis that (*a*) has its origin at the initial or final position of the object and (*b*) is oriented in the direction of motion or acceleration.
3. Specify the position and velocity at all relevant instants. In particular, specify the *initial conditions*—position and velocity at the beginning of the time interval of interest—and the *final conditions*—position and velocity at the end of that time interval. Also specify all positions where the velocity reverses direction or the acceleration changes. Label any unknown parameters with a question mark.
4. Indicate the acceleration of the object between all the instants specified in step 3.
5. To consider the motion of more than one object, draw separate diagrams side by side, one for each object, using one common x axis.
6. If the object reverses direction, separate the motion diagram into two parts, one for each direction of travel.

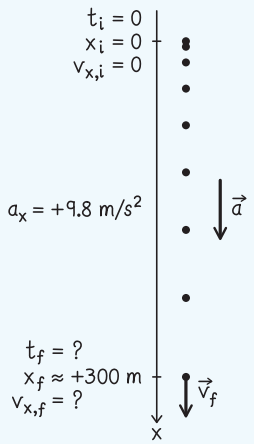
EXAMPLE 3.2 Can this be?

A newspaper article you read claims that by the time it reaches the ground, a stone dropped from the top of the Empire State Building (which has approximately 100 floors) "travels the length of a window faster than you can say *Watch out! A stone!*" Estimate whether this is true.

1 GETTING STARTED At first this problem appears ill-defined. What am I supposed to calculate? Where to begin? If the answer to the first question is not immediately clear, the answer to the second is: with a motion diagram. I therefore begin by organizing the information following the procedure in the Procedure box "Analyzing motion using motion diagrams." I show the motion represented by a series of dots of increasing spacing to represent the acceleration due to gravity (**Figure 3.11**). I chose an x axis having its origin at the top of the building (the stone's initial position) and pointing downward (in the direction of the motion). This choice of axis means that downward corresponds to the *positive* x direction—x increases as the stone falls. The initial conditions are then

$$t_i = 0, \quad x_i = 0, \quad v_{x,i} = 0.$$

The clock reading t_i and position x_i are zero because of my arbitrary choice of reference point. I could have chosen any other values, but the choice I made simplifies things later on. That the x component of the initial velocity is zero is an assumption because the problem doesn't specify this detail. All I know is that the stone is dropped, and it seems reasonable to assume it is not thrown downward or upward, but simply released from rest.



Because I am interested in the stone's speed just as it reaches the ground, I choose that instant as the final instant. To estimate the distance between the initial and final positions, I assume that each floor is about 3 m high, making the building about 300 m high.* So the final conditions are

$$t_f = ?, \quad x_f = +300 \text{ m}, \quad v_{x,f} = ?.$$

Between $x_i = 0$ and $x_f = +300$ m, the stone accelerates downward because of gravity. I make a simplifying assumption that air resistance doesn't affect the acceleration of the stone very much, so I write "$a_x = +9.8 \text{ m/s}^2$" between the initial and final positions.†

(Continued)

Figure 3.11

*The Empire State Building is 381 m high, and so my estimate is off by about 30%, but you will soon see that this error is irrelevant.

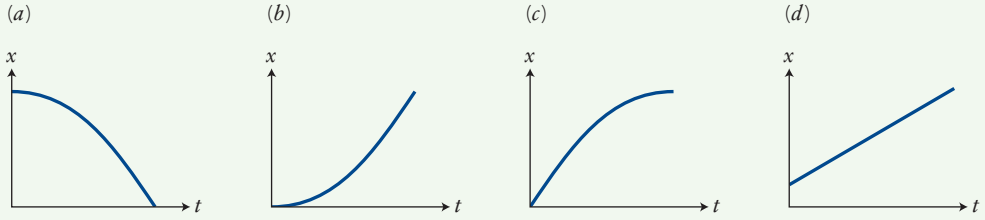
†Note that a_x is positive because both the acceleration and the x axis point downward. This assumption is almost certainly an oversimplification because air resistance cannot be ignored for a fall from about 300 m. However, we have not yet developed the tools to include air resistance, and so I have no other choice.

CONCEPTS

2 DEVISE PLAN To complete the estimating task given in the problem statement, I need to compare the speed of the stone at the bottom of its fall to the speed it would have to have if it traveled the length of a window in the same time interval it takes to say "Watch out! A stone!" Because no values are given, I'll have to use estimates and then evaluate the speed using the relation among speed, distance traveled, and acceleration.

3 EXECUTE PLAN I estimate that it takes roughly 2 s to say those words and a window is about 2 m tall. So, as long as the stone is traveling faster than $(2\text{ m})/(2\text{ s}) = 1\text{ m/s}$ just before it hits the ground, it passes by a window before the four words can be uttered. I also know that the acceleration in free fall is about 10 m/s^2, so the speed of the stone increases by 10 m/s each second. That means that the stone's speed is 10 m/s 1 s after it is released. I know from experience that it takes far longer than 1 s for an object to fall such a great distance, and so, even without further calculation, I see that the statement must be true. ✔

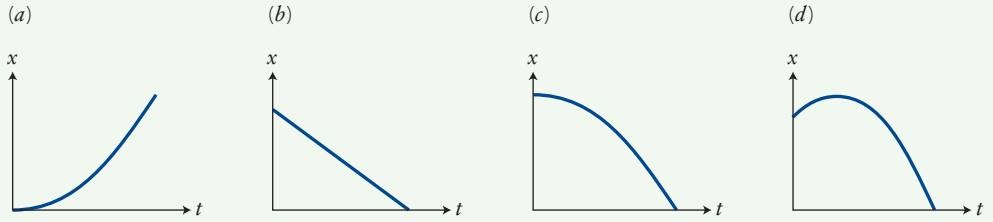
4 EVALUATE RESULT Even if I account for some slowing down due to air resistance, I know from experience that a stone dropped from even a much smaller height travels more than 1 m in 1 s just before it reaches the ground. (In the second part of this chapter, you will be able to use the motion diagram to calculate how fast the stone moves just before hitting the ground.)



3.9 Make a motion diagram for the following situation: A seaside cliff rises 30 m above the ocean surface, and a person standing at the edge of the cliff launches a rock vertically upward at a speed of 15 m/s. After reaching the top of its trajectory, the rock falls into the water.

CONCEPTS

Self-quiz



1. Two stones are released from rest at a certain height, one 1 s after the other. (*a*) Once the second stone is released, does the difference in their speeds increase, decrease, or stay the same? (*b*) Does their separation increase, decrease, or stay the same? (*c*) Is the time interval between the instants at which they hit the ground less than, equal to, or greater than 1 s? (Use $x(t)$ curves to help you visualize this problem.)
2. Which of the graphs in **Figure 3.12** depict(s) an object that starts from rest at the origin and then speeds up in the positive x direction?

Figure 3.12

3. Which of the graphs in **Figure 3.13** depict(s) an object that starts from a positive position with a positive x component of velocity and accelerates in the negative x direction?

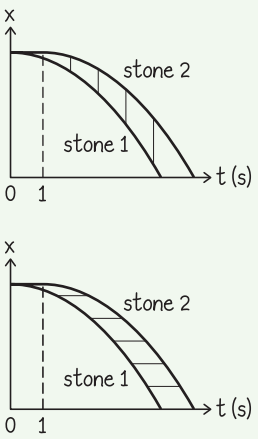
Figure 3.13

4. Draw a motion diagram for an object that initially has a negative x component of velocity but has a positive x component of acceleration. (Include motion in one direction only.)

Answers

1. (*a*) Both stones accelerate at about 10 m/s^2, and so the speed of each increases about 10 m/s each second. Because the speeds increase at the same rate, the difference in the speeds remains the same. (*b*) As indicated by the vertical lines between the $x(t)$ curves for both stones in **Figure 3.14**, the separation increases because the speed of the first stone is always greater. (*c*) Both stones execute the same motion—they start from rest and have the same acceleration and travel the same distance. So the second stone always remains 1 s behind (the $x(t)$ curves are separated horizontally by 1 s at all instants; see the horizontal lines separating the curves in Figure 3.14). Therefore the second stone hits the ground 1 s after the first one hits.
2. Graph *b* is the correct answer because its initial position is zero and the slope is initially zero but then increasing, indicating that the object speeds up. Graph *a* depicts a motion that does not begin at the origin and has the object speeding up in the negative x direction. Graph *c* depicts an object slowing down while moving in the positive x direction. Graph *d* depicts an object that is initially not at the origin and that moves at constant velocity in the positive x direction.
3. Graph *d*. Graph *a* does not have a positive initial position. Graph *b* represents zero acceleration. Graph *c* represents zero initial velocity.
4. An object that has a negative x component of velocity must slow down in order to have a positive x component of acceleration. **Figure 3.15** shows what a motion diagram for this situation looks like.

Figure 3.14



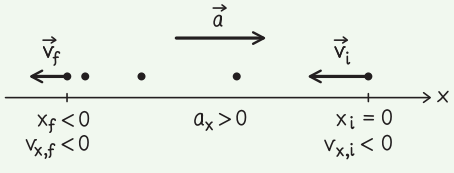


Figure 3.15

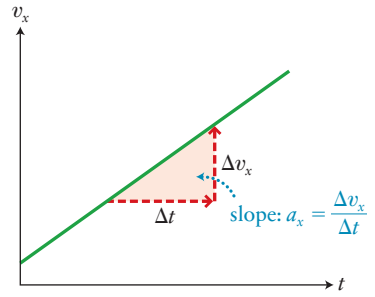
3.5 Motion with constant acceleration

As we saw in Section 3.1, the x component of the average acceleration is the change in the x component of the velocity divided by the time interval during which this change took place:

$$a_{x,\text{av}} \equiv \frac{\Delta v_x}{\Delta t} = \frac{v_{x,\text{f}} - v_{x,\text{i}}}{t_\text{f} - t_\text{i}}. \tag{3.1}$$



Notice the similarity between this definition and the definition of average velocity (Eq. 2.14):

$$v_{x,\text{av}} \equiv \frac{\Delta x}{\Delta t} = \frac{x_\text{f} - x_\text{i}}{t_\text{f} - t_\text{i}}. \tag{3.2}$$

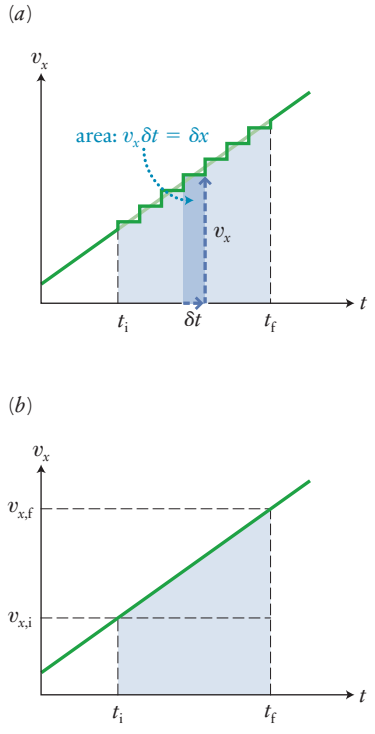
Velocity is the rate of change in position, and acceleration is the rate of change in velocity.

Let us begin by analyzing motion with constant acceleration. The x component of the velocity of an object whose acceleration is constant increases by equal amounts Δv_x during equal time intervals Δt. For example, the x component of the velocity of an object that has a constant acceleration $a_x = +5\ \text{m/s}^2$ increases by 5 m/s each second. If we plot the object's x component of velocity versus time, we therefore get a straight line with a nonzero slope, as in **Figure 3.16**.

Figure 3.16 For an object moving with constant acceleration, the $v_x(t)$ curve is a straight line.

To obtain an expression that allows us to determine the x component of the final velocity $v_{x,\text{f}}$ at some final instant t_f, we rewrite Eq. 3.1 in the form*

$$\Delta v_x \equiv v_{x,\text{f}} - v_{x,\text{i}} = a_x \Delta t \quad \text{(constant acceleration)} \tag{3.3}$$



or

$$v_{x,\text{f}} = v_{x,\text{i}} + a_x \Delta t \quad \text{(constant acceleration)}. \tag{3.4}$$

So, if we know the x component of the initial velocity $v_{x,\text{i}}$ at some initial instant t_i for an object moving with constant acceleration, we add $a_x \Delta t$ to this x component of the velocity to obtain the x component of the final velocity $v_{x,\text{f}}$ at a later instant $t_\text{f} = t_\text{i} + \Delta t$.

How do we determine the displacement Δx for an accelerating object? In Section 2.8 we learned that the displacement of an object moving at constant velocity is equal to the area under the $v_x(t)$ curve. The motion we are considering now is not at constant velocity because acceleration is involved, but we can still apply what we know. We begin by approximating the $v_x(t)$ curve of Figure 3.16 by the stepped curve shown at the top of the shaded area in **Figure 3.17a**. The shaded area consists of many small rectangles of equal width δt adjusted in height to fit under the stepped $v_x(t)$ curve. (We use a lowercase Greek delta, δ, instead of an uppercase delta, Δ, to indicate that the time interval is small.) The area of each rectangle gives the displacement δx during an interval δt, and this area is the x component of the velocity at the beginning of the time interval multiplied by δt. The total displacement $\Delta x = x_\text{f} - x_\text{i}$ in the time interval from t_i to t_f is approximately equal to the sum of the areas of all the rectangles. The smaller the width of the rectangles, the more accurate the approximation.

Figure 3.17 Determining the displacement for an object with constant acceleration.

*Because the acceleration is constant, it always has the same (average) value, and so we can drop the subscript av.

QUANTITATIVE TOOLS

In the limit that Δt approaches zero, the displacement $\Delta x = x_f - x_i$ is given exactly by the trapezoidal area under the $v_x(t)$ curve between t_i and t_f in Figure 3.17*b*. This area is equal to the sum of the areas of the shaded triangle and rectangle in Figure 3.17*b*. The area of the triangle is

$$\tfrac{1}{2}(v_{x,f} - v_{x,i})(t_f - t_i) = \tfrac{1}{2}\Delta v_x\, \Delta t = \tfrac{1}{2}\, a_x(\Delta t)^2, \tag{3.5}$$

where I have used Eq. 3.3 to substitute $a_x \Delta t$ for Δv_x. The area of the rectangle is

$$(v_{x,i} - 0)(t_f - t_i) = v_{x,i}\Delta t. \tag{3.6}$$

The displacement is thus the sum of Eqs. 3.5 and 3.6:

$$x_f - x_i = v_{x,i}\Delta t + \tfrac{1}{2}a_x(\Delta t)^2 \quad \text{(constant acceleration)}, \tag{3.7}$$

and the object's final position is

$$x_f = x_i + v_{x,i}\Delta t + \tfrac{1}{2}a_x(\Delta t)^2 \quad \text{(constant acceleration)}. \tag{3.8}$$

Equations 3.4 and 3.8 can be written without the delta notation when we reset our clock to zero at the beginning of a motion segment, so that $t_i = 0$ and $\Delta t = t_f - t_i = t_f$. Equations 3.8 and 3.4 then become, respectively,

$$x_f = x_i + v_{x,i}t_f + \tfrac{1}{2}a_x t_f^2 \quad \text{(constant acceleration)} \tag{3.9}$$

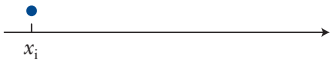
and

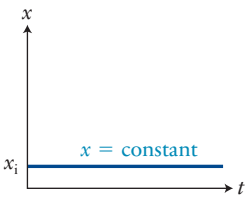
$$v_{x,f} = v_{x,i} + a_x t_f \quad \text{(constant acceleration)}, \tag{3.10}$$

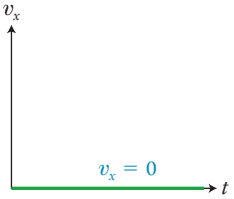
giving us the position and the x component of the velocity of an object at any instant t_f.

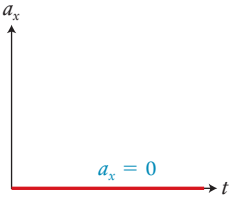
Equations 3.9 and 3.10 are the basic equations for motion at constant acceleration when the initial conditions at $t_i = 0$ are known. Note that when $a_x = 0$, these equations become identical to the equations for motion at constant velocity: Eq. 3.10 yields an x component of the velocity v_x that is constant, and Eq. 3.9 becomes identical to Eq. 2.19.

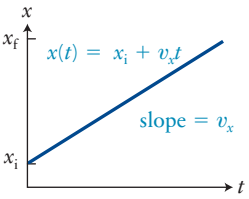
Equation 3.9 gives the final position of an object at instant t_f. Because this instant is arbitrary, we can drop the subscript f to obtain an expression for the $x(t)$ curve of an object moving at constant acceleration:

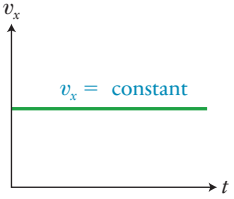


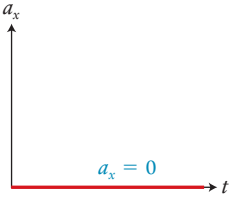


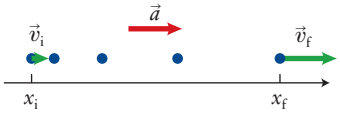


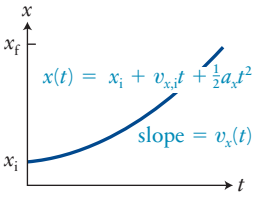


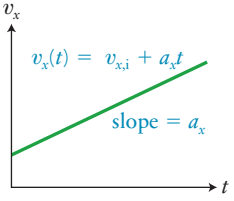


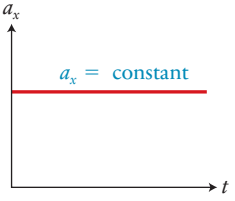












$$x(t) = x_i + v_{x,i}t + \tfrac{1}{2}a_x t^2 \quad \text{(constant acceleration)}. \tag{3.11}$$

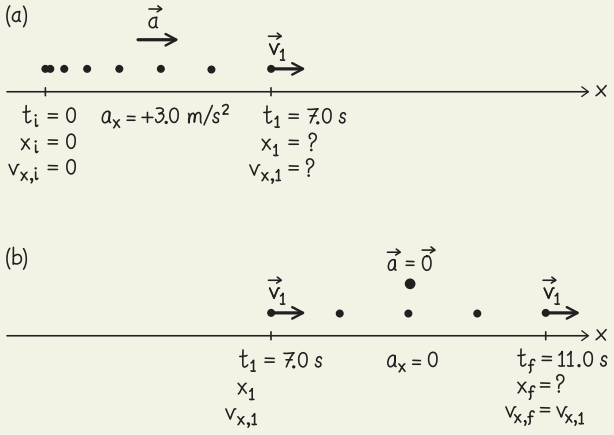
This expression shows that, for motion with constant acceleration, position depends on the square of t, and the $x(t)$ curve is thus a parabola. If a_x is positive, the parabola curves upward; if it is negative, the parabola curves downward (for an example, see Figure 3.8*c*). Likewise, from Eq. 3.10 we see that the $v_x(t)$ curve for motion at constant acceleration is a straight line:

$$v_x(t) = v_{x,i} + a_x t \quad \text{(constant acceleration)}. \tag{3.12}$$

For motion at constant velocity, we can set $a_x = 0$ in Eqs. 3.11 and 3.12, yielding straight lines for both $x(t)$ and $v_x(t)$. **Table 3.1** summarizes the three basic types of motions we have studied so far: at rest, constant velocity, and constant acceleration.

Table 3.1 Kinematics graphs for three basic types of motion

Motion diagram	Position versus time	Velocity versus time	Acceleration versus time
At rest 			
Constant velocity 			
Constant acceleration 			



EXAMPLE 3.3 Accelerating car, again

Use Eqs. 3.11 and 3.12 to determine how far the car in Exercise 3.1 travels.

❶ **GETTING STARTED** To quantitatively analyze the situation in Exercise 3.1, I begin by separating the motion diagram in Figure 3.10 into two parts: one representing the acceleration of the car (**Figure 3.18*a***) and one representing its motion at constant speed (Figure 3.18*b*). Note that the initial position and velocity in Figure 3.18*b* are not labeled with a question mark; even though they are not given, they are identical to the final position and velocity in Figure 3.18*a*, and so their values can be determined by solving the first part of the problem. The only unknown in the second part is the final position of the car.

❷ **DEVISE PLAN** Equation 3.11 allows me to determine the position of the accelerating car during the first part of the motion. To calculate the distance traveled during the second part of the motion, I need to know the velocity of the car. I can obtain this velocity from Eq. 3.12. From Eq. 2.18, I know that the distance traveled is then the product of this constant velocity and the duration of the time interval (4.0 s). Adding this distance to the position of the car at the end of the first part of the motion then gives me the total distance traveled by the car.

Figure 3.18

❸ **EXECUTE PLAN** Given that $x_i = 0$ and $v_{x,i} = 0$, Eq. 3.11 reduces to $x_1 = x(t_1) = \frac{1}{2}a_x t_1^2$. Substituting $a_x = +3.0\ \text{m/s}^2$ and $t_1 = 7.0\ \text{s}$, I obtain for the position of the car at the end of the first part of the motion:

$$x_1 = \tfrac{1}{2}(+3.0\ \text{m/s}^2)(7.0\ \text{s})^2 = +74\ \text{m}.$$

QUANTITATIVE TOOLS

From Eq. 3.12, I obtain the velocity at the beginning of the second interval:

$$v_1 = 0 + (+3.0\ \text{m/s}^2)(7.0\ \text{s}) = +21\ \text{m/s}.$$

At this constant velocity, the car's displacement during the 4.0 s of the second interval is

$$\Delta x = v_{x,1}\Delta t = (+21\ \text{m/s})(11.0\ \text{s} - 7.0\ \text{s}) = +84\ \text{m},$$

and so the x component of the car's total displacement is $(+74\ \text{m}) + (+84\ \text{m}) = +158\ \text{m}$. The car in Exercise 3.1 thus traveled a distance of 158 m. ✔

4 EVALUATE RESULT With an acceleration of $3.0\ \text{m/s}^2$ (about one-third of the acceleration due to gravity), the car reaches a speed of

$$\frac{21\ \text{m}}{1\ \text{s}} \times \frac{1\ \text{mi}}{1609\ \text{m}} \times \frac{3600\ \text{s}}{1\ \text{h}} = 47\ \text{mi/h}$$

over the 7.0 s of the first interval and travels a distance of 74 m or about the length of a sports field. Both the car's final speed and the distance traveled are in line with what I would expect. During the second part of the motion, the car travels roughly the same distance in 4.0 s, which is also reasonable.

EXAMPLE 3.4 Collision or not?

You are bicycling at a steady 6.0 m/s when someone suddenly walks into your path 2.5 m ahead. You immediately apply the brakes, which slow you down at $6.0\ \text{m/s}^2$. Do you stop in time to avoid a collision?

1 GETTING STARTED In order to avoid a collision, you must come to a stop in less than 2.5 m. The problem therefore boils down to calculating the distance traveled under the given conditions and comparing this distance to 2.5 m.

2 DEVISE PLAN Equation 3.7 gives me the displacement, but I don't know the time interval Δt. I can obtain this time interval from Eq. 3.4: $\Delta t = (v_{x,\text{f}} - v_{x,\text{i}})/a_x$, which contains no unknowns on the right side.

3 EXECUTE PLAN Substituting the expression for the time interval from Eq. 3.4 into Eq. 3.7 gives the x component of the displacement necessary to stop:

$$\Delta x = v_{x,\text{i}}\frac{v_{x,\text{f}} - v_{x,\text{i}}}{a_x} + \tfrac{1}{2}a_x\left(\frac{v_{x,\text{f}} - v_{x,\text{i}}}{a_x}\right)^2 = \frac{v_{x,\text{f}}^2 - v_{x,\text{i}}^2}{2a_x}. \qquad (1)$$

When I let the x axis point in the direction of the motion, the x component of the initial velocity is $v_{x,\text{i}} = +6.0\ \text{m/s}$, the x component of the final velocity is zero, $v_{x,\text{f}} = 0$, and the x component of the acceleration is $a_x = -6.0\ \text{m/s}^2$. Substituting these values into Eq. 1, I get

$$\Delta x = \frac{0 - (+6.0\ \text{m/s})^2}{2(-6.0\ \text{m/s}^2)} = +3.0\ \text{m},$$

which is more than the 2.5 m separating you from the person walking into your path. You will not be able to stop in time to avoid a collision. ✔

4 EVALUATE RESULT Because $a_x = -6.0\ \text{m/s}^2$, your speed decreases by 6.0 m/s each 1 s, and so it takes 1 s to come to a stop from your initial speed of 6.0 m/s. Because your speed is decreasing, you travel less than 6.0 m, but without carrying out the calculation, I can't tell whether or not that distance is less than 2.5 m. All I can really say is that my answer should be less than 6.0 m, which it is.

Equation 3.4 allows us to determine the x component of the final velocity of an object undergoing constant acceleration after a certain time interval Δt. By multiplying both sides of Eq. 1 in Example 3.4 by $2a_x$ and rearranging terms, I get an expression for the x component of the final velocity of an object undergoing constant acceleration over a certain displacement Δx:

$$v_{x,\text{f}}^2 = v_{x,\text{i}}^2 + 2a_x\Delta x \quad \text{(constant acceleration)}. \qquad (3.13)$$

3.10 Determine the velocity of the stone dropped from the top of the Empire State Building in Example 3.2 just before the stone hits the ground.

3.6 Free-fall equations

The magnitude of the **acceleration due to gravity** is designated by the letter g:

$$g \equiv |\vec{a}_{\text{free fall}}|. \qquad (3.14)$$

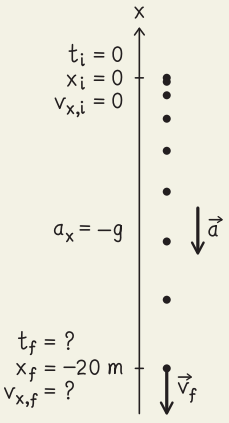
As noted in Section 3.2, near Earth's surface the magnitude of the acceleration due to gravity is $g = 9.8\ \text{m/s}^2$. The direction of this acceleration is

always downward, and so if we choose a positive x axis that points upward, the x component of the acceleration due to gravity is given by $a_x = -g$, where the minus sign takes into account that the acceleration vector points downward.

If an object is dropped from a certain height with zero initial velocity along an upward-pointing x axis, then, according to Eqs. 3.9 and 3.10,

$$x_f = x_i - \tfrac{1}{2}gt_f^2 \tag{3.15}$$

and



$$v_{x,f} = -gt_f. \tag{3.16}$$

EXAMPLE 3.5 Dropping the ball

Suppose a ball is dropped from height $h = 20$ m above the ground. How long does it take to hit the ground, and what is its velocity just before it hits?

❶ **GETTING STARTED** I begin by drawing a motion diagram, arbitrarily choosing an x axis that points upward and has its origin at the initial position of the ball (Figure 3.19). I make two simplifying assumptions: that the ball is released from rest ($v_{x,i} = 0$ at $t_i = 0$) and that I may ignore air resistance (so that the ball is in free fall).

Figure 3.19

When the ball is released from rest at the origin, the initial conditions are

$$t_i = 0, \quad x_i = 0, \quad v_{x,i} = 0.$$

The final position x_f at instant t_f is a distance h below the initial position, and so, just before impact at instant t_f, the final conditions are

$$t_f = ?, \quad x_f = -h, \quad v_{x,f} = ?.$$

As the ball falls, its acceleration is negative (because $\vec{a}$ points toward increasingly negative values of x), and so $a_x = -g$.

❷ **DEVISE PLAN** Because the acceleration of the ball is constant, I can use Eqs. 3.9 and 3.10. Doing so gives me two equations to determine the two unknowns t_f and $v_{x,f}$.

❸ **EXECUTE PLAN** Substituting the initial and final conditions into Eq. 3.9 yields

$$-h = 0 + 0 - \tfrac{1}{2}gt_f^2 = -\tfrac{1}{2}gt_f^2,$$

and so

$$t_f = \sqrt{\frac{2h}{g}}.$$

Substituting $h = 20$ m and $g = 9.8$ m/s^2, I obtain for the amount of time the ball takes to fall 20 m

$$\Delta t = t_f - t_i = \sqrt{\frac{2h}{g}} - 0 = \sqrt{\frac{2(20\text{ m})}{9.8\text{ m/s}^2}} = \sqrt{4.0\text{ s}^2}$$

$$= 2.0\text{ s.} \checkmark \tag{1}$$

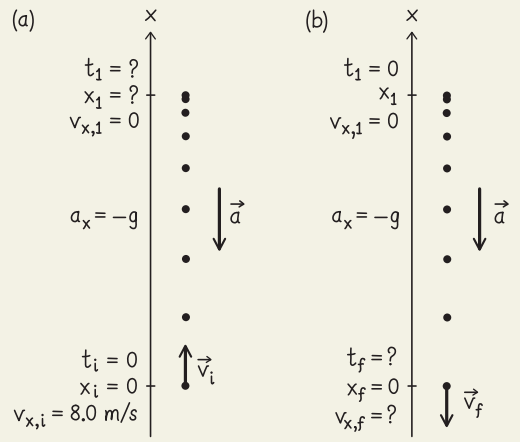
Next I use Eq. 3.10. Because the ball starts from rest, I have

$$v_{x,f} = 0 - gt_f = -gt_f = -(9.8\text{ m/s}^2)(2.0\text{ s})$$

$$= -20\text{ m/s.} \checkmark$$

❹ **EVALUATE RESULT** The 2.0 s I obtained for the time interval it takes the ball to fall is not unreasonable: 20 m corresponds approximately to the height of a six-story building, and from experience I know that something dropped from such a height takes a few seconds to reach the ground. My answer for the final velocity $v_{x,f} = -20$ m/s also makes sense: The x component of the velocity is negative because it points in the negative x direction, and if the ball were moving always at a constant speed of 20 m/s, it would cover the 20-m distance in 1 s. Because it moves at that speed only at the end of the drop, it takes longer to fall, as Eq. 1 shows.

3.11 Repeat Example 3.5 for an x axis that points downward (leaving the origin at the ball's initial position).



QUANTITATIVE TOOLS

EXAMPLE 3.6 A stone launched up

A stone is launched straight up from ground level at a speed of 8.0 m/s. (*a*) How high does it rise? (*b*) How many seconds does it take for the stone to hit the ground?

❶ **GETTING STARTED** I am asked to consider two parts of the trajectory: part *a* from the launch position to the top of the trajectory and part *b* from the launch position to the top and back down to the launch position. I begin therefore by drawing two motion diagrams: one for the upward motion and the other for the downward motion. I (arbitrarily) choose an x axis pointing upward, put the origin at the launching position, and start the clock at $t_i = 0$ at the instant the stone is launched (**Figure 3.20**).

Figure 3.20

For the upward motion (Figure 3.20*a*), the initial conditions are $t_i = 0$, $x_i = 0$, and $v_{x,i} = +8.0$ m/s. The hard part of this problem is specifying the final conditions, and here is where the motion diagram helps. I know neither the instant t_1 at which the highest position is reached nor the location x_1 of that position. I do, however, know *something* about the stone at the highest position. (Put the book down and think for a second—you know it, too.)

The key is the word *highest:* The stone reverses direction at the highest position, and so its velocity must be zero there. So, for the upward part of the motion, the stone's final conditions are $t_f = t_1 = ?$, $x_f = x_1 = ?$ and $v_{x,f} = v_{x,1} = 0$.

For the downward motion, I reset the clock to zero at the top, as indicated by $t_1 = 0$ in Figure 3.20*b*. Doing this simplifies the calculation because it makes this part of the problem nearly identical to Example 3.5. I should not forget, however, that $\Delta t = t_f - t_i = t_f - 0 = t_f$ now represents the duration of the downward motion only, not the total duration for the upward and downward travel.

❷ **DEVISE PLAN** To determine the height reached by the stone, I need to obtain a value for x_1. The stone is undergoing constant acceleration, so its position and velocity are given by Eqs. 3.8 and 3.4. For the upward part of the motion I see from my motion diagram that there are two unknowns (x_1 and t_1), and so the number of unknowns is equal to the number of equations. After I obtain x_1 and t_1, the downward part of the motion also contains two unknowns ($v_{x,f}$ and t_f), which I can calculate using the same two equations.

❸ **EXECUTE PLAN** (*a*) For the upward portion of the motion I can use Eqs. 3.9 and 3.10 instead of Eqs. 3.8 and 3.4 because the clock reads zero at the beginning of the motion. With the x axis pointing upward, the acceleration of the stone is $a_x = -g$, and so these equations become

$$x_1 = 0 + v_{x,i}t_f - \tfrac{1}{2}gt_f^2 \tag{1}$$

and

$$0 = v_{x,i} - gt_f. \tag{2}$$

Solving Eq. 2 for t_f, I get

$$t_f = \frac{v_{x,i}}{g} = \frac{+8.0\text{ m/s}}{9.8\text{ m/s}^2} = 0.82\text{ s}. \tag{3}$$

Substituting this result into Eq. 1, I determine the height to which the stone rises

$$x_1 = v_{x,i}\left(\frac{v_{x,i}}{g}\right) - \tfrac{1}{2}g\left(\frac{v_{x,i}}{g}\right)^2 = \frac{v_{x,i}^2}{g} - \frac{v_{x,i}^2}{2g} = \frac{v_{x,i}^2}{2g}, \tag{4}$$

and so

$$x_1 = \frac{(+8.0\text{ m/s})^2}{2(9.8\text{ m/s}^2)} = +3.3\text{ m}. \checkmark$$

(*b*) For the downward part of the motion, Eq. 3.7 becomes

$$0 - x_1 = 0 - \tfrac{1}{2}g(t_f - t_1)^2.$$

Rearranging terms and substituting Eq. 4 for x_1, I have

$$(t_f - t_1)^2 = \frac{2x_1}{g} = \frac{2v_{x,i}^2}{2g^2} = \left(\frac{v_{x,i}}{g}\right)^2,$$

which shows that the amount of time it takes for the stone to fall back to the ground, $\Delta t = t_f - t_1 = v_{x,i}/g$, is identical to the amount of time it takes for the stone to reach its highest position (see Eq. 3).

The amount of time it takes for the round trip is

$$t_f = 2\left(\frac{v_{x,i}}{g}\right) = 2\left(\frac{8.0\text{ m/s}}{9.8\text{ m/s}^2}\right) = 1.6\text{ s}. \checkmark$$

❹ **EVALUATE RESULT** That it takes as much time to travel up as it takes to fall back down makes sense if you look at the position-versus-time graph for a projectile in Figure 3.8*c*. The parabola is symmetrical about the maximum, meaning that the acceleration is the same in both directions, and so both parts of the motion must take the same amount of time. The stone's initial velocity is 8.0 m/s, so at an acceleration of about 10 m/s^2, it should take 0.8 s to slow down to zero and reach its highest position. The downward part of the motion is similar to the upward part, with the motion reversed, and so the total time should be twice as long. At a constant 8.0 m/s, the stone would travel (0.8 s)(8.0 m/s) = 6.4 m, but because it slows it travels only half that distance. My answers appear to make sense!

3.12 In Example 3.6, what is the x component of the velocity of the stone just before it hits the ground?

3.7 Inclined planes

Galileo concluded that the acceleration due to gravity is constant even though he was unable to study falling objects using high-speed video or multiple-flash photography. Instead, he used inclined planes at shallow angles of incline to reduce the acceleration. By rolling balls along such inclined planes, he came to the following remarkable conclusion:

When a ball rolls down an incline starting from rest, the ratio of the distance traveled to the square of the amount of time needed to travel that distance is constant.

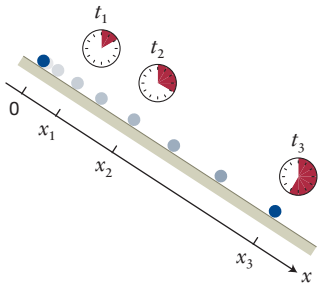


Figure 3.21 Galileo measured how long it takes a ball to roll down planes inclined at different angles and concluded that the acceleration due to gravity is constant.

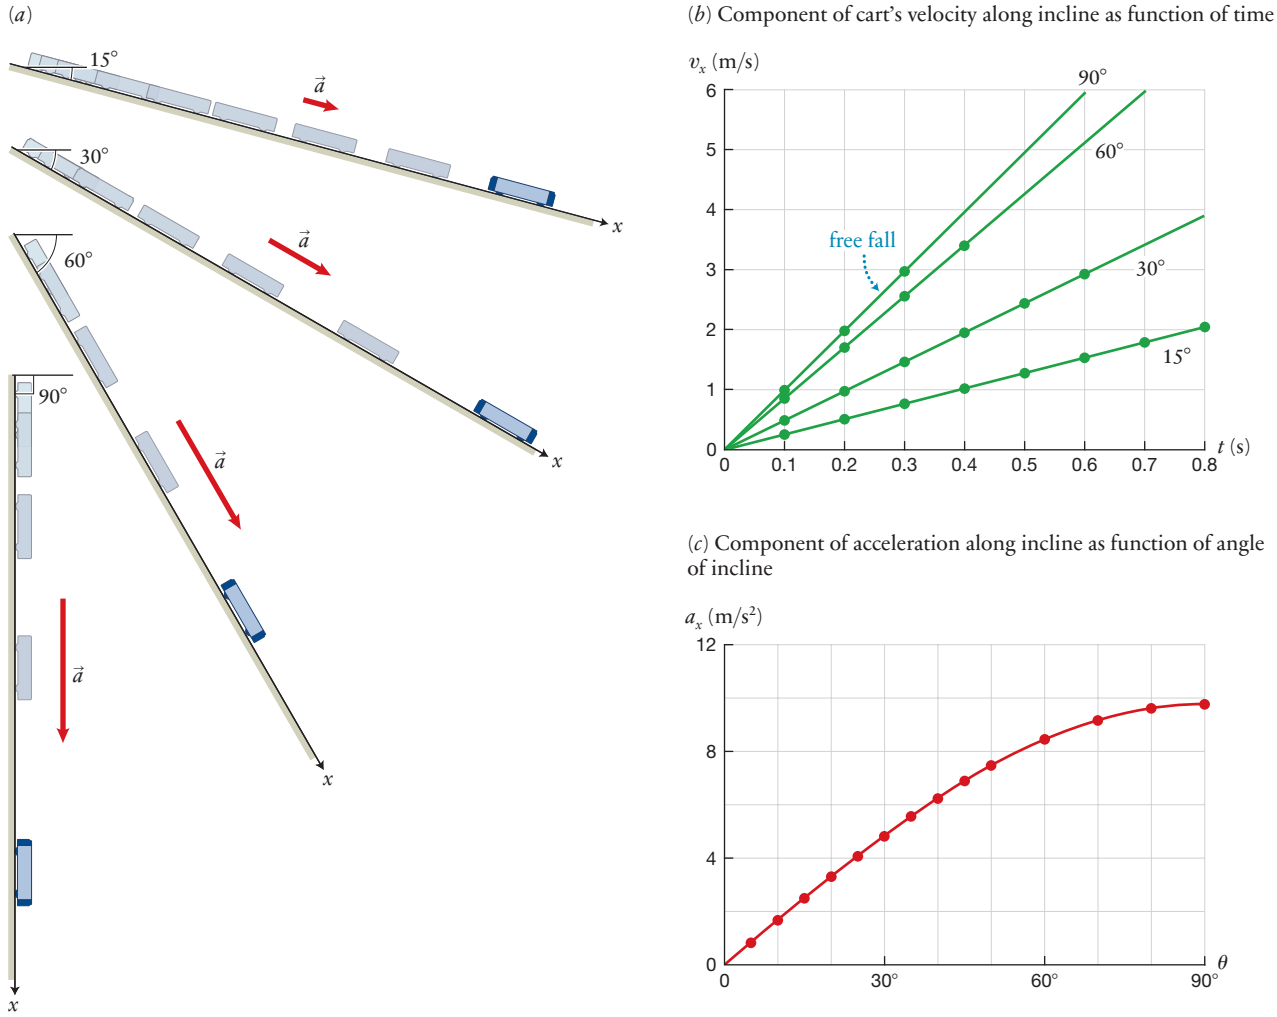
For instance, if a ball released from position $x_i = 0$ at $t_i = 0$ reaches position x_1 at instant t_1, x_2 at t_2, and x_3 at t_3 (**Figure 3.21**), Galileo found experimentally that

$$\frac{x_1}{t_1^2} = \frac{x_2}{t_2^2} = \frac{x_3}{t_3^2}. \tag{3.17}$$

Note that for an object moving with constant acceleration and starting from rest at $x_i = 0$ and $t_i = 0$, we have, from Eq. 3.9,

$$x_f = \tfrac{1}{2} a_x t_f^2, \tag{3.18}$$

so that



$$\frac{x_f}{t_f^2} = \tfrac{1}{2} a_x, \tag{3.19}$$

which tells us that Galileo's ratio (Eq. 3.17) is directly proportional to the x component of the acceleration. The fact that the ratio doesn't change as the ball rolls down the incline demonstrates that the acceleration is constant.

When Galileo increased the angle of the incline, the ratio x_f/t_f^2 increased, too, although for any fixed angle it remained constant regardless of the distance covered by the ball. Galileo was able to study only a limited range of angles, but he conjectured that for a given angle of incline the ratio x_f/t_f^2 would remain constant. For a vertical incline, he reasoned, the ball would be in free fall and still have a constant acceleration.

We saw in Section 3.2 that Galileo's conjecture was correct. **Figure 3.22*a*** shows a low-friction cart rolling down inclines of different angles. For each angle, the component of the velocity along the incline increases linearly with time, indicating that the component of the acceleration along the incline is constant for that angle. Moreover, the component of the acceleration along the incline (the slope of the lines in Figure 3.22*b*) becomes larger as the angle is increased. Figure 3.22*c* shows how the component of the acceleration along the incline varies with the angle of incline θ. Experimentally we

Figure 3.22 The acceleration of a low-friction cart rolling down an incline increases as the angle of incline increases.

determine that the component of the acceleration along the incline obeys the relationship

$$a_x = +g \sin \theta \tag{3.20}$$

when the x axis points downward along the incline. For a vertical incline, $\theta = 90°$ and Eq. 3.20 correctly yields the x component of the acceleration of a freely falling object.

3.13 As the angle θ of the incline used to collect the data of Figure 3.22 is increased beyond 90°, what happens to the acceleration? Does this result make sense (provided you always put the cart on the top side of the track)?

3.8 Instantaneous acceleration

So far, we have discussed only motion that has constant acceleration, but not all acceleration is constant. For example, when a car accelerates, the acceleration levels off as the car approaches top speed. This is illustrated in Figure 3.23. If the car's acceleration were constant, the $v_x(t)$ curve would

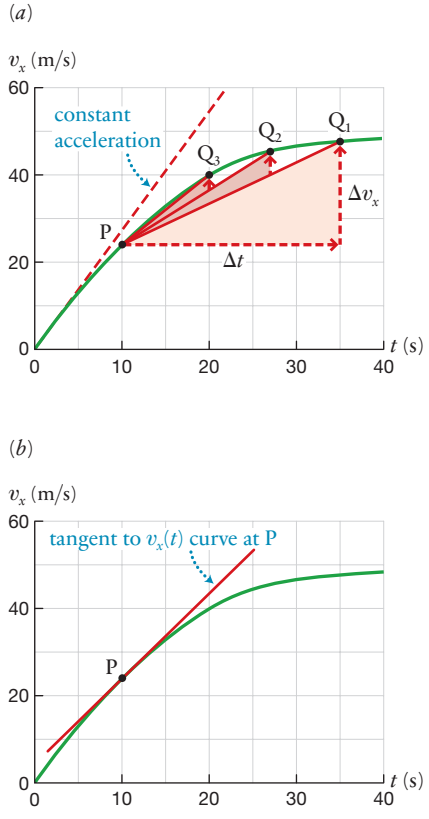


Figure 3.23 Velocity-versus-time graphs for an accelerating car. (*a*) As the time interval Δt over which the x component of the acceleration is averaged gets smaller, Δv_x gets smaller and the straight-line segment PQ approaches the tangent to the curve at P. (*b*) The slope of the tangent to the curve at P gives the x component of the instantaneous acceleration at that instant.

be the dashed straight line in Figure 3.23*a*; instead, the x component of the velocity levels off at about +50 m/s.

To determine the car's acceleration at a given instant, we follow the procedure of successive approximations we used in Section 2.9 to determine instantaneous velocity. Suppose we are interested in the x component of the car's acceleration 10 s after it begins accelerating. The x component of the *average* acceleration is obtained by dividing the change in the x component of the velocity during a certain time interval by the duration of that time interval (Eq. 3.1). For example, the x component of the car's average acceleration during the 25-s time interval following the instant we are interested in is given by the slope of the straight line segment PQ_1 in Figure 3.23*a*. To obtain the x component of the acceleration at $t = 10$ s, we make the time interval Δt over which we evaluate Δv_x successively shorter. As Δt approaches zero, the straight line segment PQ becomes tangent to the $v_x(t)$ curve at P, and the ratio $\Delta v_x/\Delta t$ approaches the x component of the **instantaneous acceleration** (or simply **acceleration**)* at point P:

$$a_x \equiv \lim_{\Delta t \to 0} \frac{\Delta v_x}{\Delta t}. \tag{3.21}$$

The right side of Eq. 3.21 is the definition of the derivative of v_x with respect to t, and so

$$a_x = \frac{dv_x}{dt}. \tag{3.22}$$

Note that the result is again a function of time. The acceleration-versus-time graph for the accelerating car of Figure 3.23 is shown in **Figure 3.24**. The slope of the $v_x(t)$ curve at a given point along the curve of Figure 3.23*b* gives the x component of the acceleration at that instant. For example, the value of the x component of the acceleration 10 s after the car begins accelerating is equal to the slope of the tangent to the $v_x(t)$ curve at point P (of Figure 3.23*b*).

In Section 2.9 we saw that the slope of the $x(t)$ curve for an object gives the x component of the object's velocity. Now we see that the slope of the $v_x(t)$ curve gives the x component of the object's acceleration:

$$\begin{array}{lcccc} & \textit{slope of} & & \textit{slope of} & \\ & x(t)\ \textit{curve} & x \text{ component of} & v_x(t)\ \textit{curve} & x \text{ component of} \\ \text{position } x & \longrightarrow & \text{instantaneous} & \longrightarrow & \text{instantaneous} \\ & & \text{velocity } \vec{v} & & \text{acceleration } \vec{a}. \end{array}$$

Mathematically this can be expressed as

$$a_x = \frac{dv_x}{dt} = \frac{d}{dt}\left(\frac{dx}{dt}\right) \equiv \frac{d^2x}{dt^2}, \tag{3.23}$$

where the expression on the right side represents the *second derivative* (the "derivative of the derivative") of x with respect to t.

Equation 3.23 allows us to obtain the x component of the acceleration of an object from its position. Often we are interested in the inverse procedure, however: What is the displacement during a given time interval for, say, the varying acceleration shown in Figure 3.24? The trick is to apply

*As with velocity, the word *instantaneous* is implied whenever we say "acceleration." Only when we want to speak of *average* acceleration will we use the adjective.

what we know about constant-acceleration motion over time intervals small enough to make the acceleration approximately constant over that time interval.

Suppose we want to know the displacement during the time interval between t_i and t_f. We first obtain the change in velocity during that time interval and then calculate the displacement.

We begin by dividing up the time interval between t_i and t_f into a number of equal shorter intervals δt and approximating the acceleration by the stepped series of short segments of constant acceleration as shown in Figure 3.24*a*. Applying Eq. 3.3 to each shorter interval δt, we can write the x component of the change in velocity during each segment as

$$(\Delta v_x)_n = a_x(t_n)\delta t, \tag{3.24}$$

where $n = 1, 2, \ldots, 7$ and $a_x(t_n)$ is the x component of the acceleration at t_n (this instant is at the middle of each short interval shown in Figure 3.24*a*). The product $a_x(t_n)\delta t$ is the area of the dark shaded rectangle in Figure 3.24*b*. The x component of the velocity change during the entire interval from t_i to t_f is then approximately equal to the sum of the $(\Delta v_x)_n$ for all the short intervals δt between t_i and t_f:

$$\Delta v_x \approx \sum_n (\Delta v_x)_n = \sum_n a_x(t_n)\delta t, \tag{3.25}$$

where $\sum a_x(t_n)\delta t$ represents the sum of all the rectangular areas under the steps between t_i and t_f (the light shaded area in Figure 3.24*b*).

To get a better approximation, we can divide the time interval $t_f - t_i$ into a larger number of smaller intervals δt, so that the variation of the acceleration over each interval becomes even smaller and the red stepped curve is closer to the actual (light red) $a_x(t)$ curve.

An exact result is obtained if we let δt approach zero (and the number of small intervals approaches infinity), as in Figure 3.24*c*:

$$\Delta v_x = \lim_{\delta t \to 0} \sum_n a_x(t_n)\delta t, \tag{3.26}$$

which is precisely the definition of the *integral* of the x component of the acceleration with respect to t from t_i to t_f:

$$\Delta v_x = \int_{t_i}^{t_f} a_x(t)dt. \tag{3.27}$$

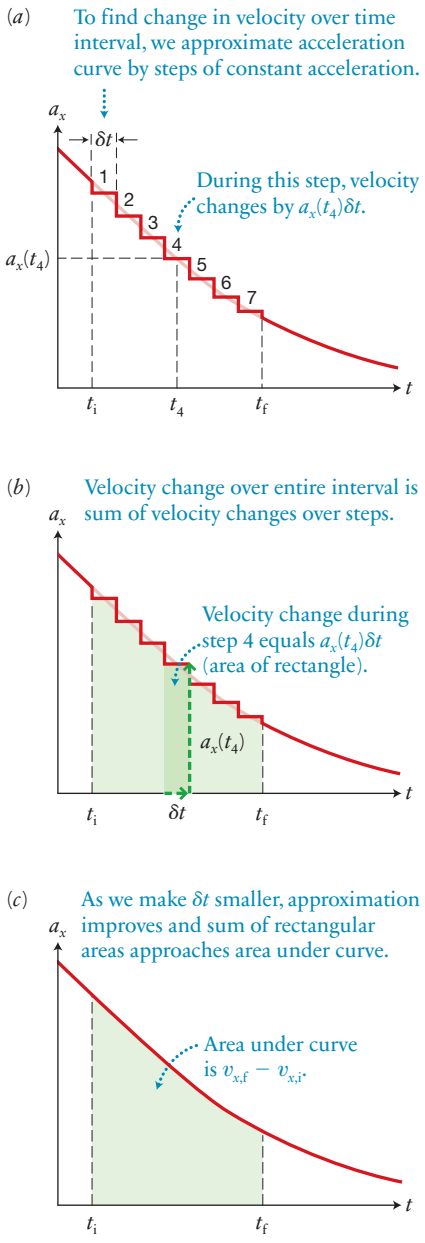
This integral represents the area under the $a_x(t)$ curve between t_i and t_f in Figure 3.24*c*. Integrals, like derivatives, can be evaluated mathematically, providing us with a convenient method for calculating the right side of Eq. 3.27 and allowing us to determine velocity from acceleration.

Once we know the velocity, we can use the same approach to obtain the displacement from the velocity. **Figure 3.25** graphically shows how to determine the x component of the displacement by evaluating the area under the $v_x(t)$ curve. In analogy to Eq. 3.27 we can thus write

$$\Delta x = \int_{t_i}^{t_f} v_x(t)dt. \tag{3.28}$$

This expression allows us to mathematically determine the x component of the displacement from a $v_x(t)$ curve. The x component of the velocity, in turn, can be obtained from the $a_x(t)$ curve (Eq. 3.27).

Figure 3.24 Determining the change in the x component of the velocity for an accelerating object.



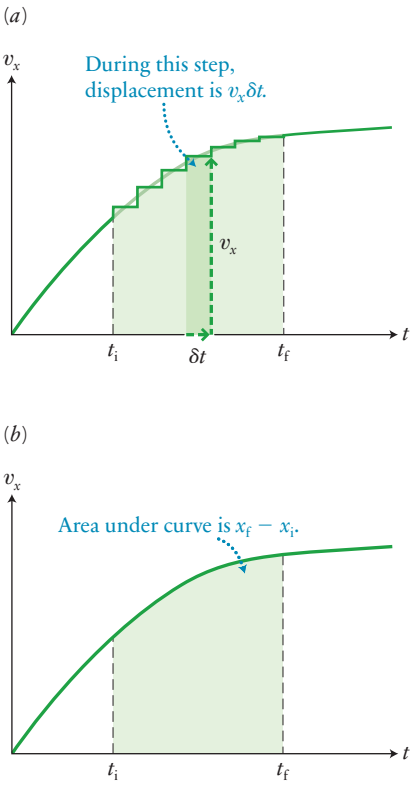


Figure 3.25 (*a*) To determine the *x* component of the displacement, we approximate the $v_x(t)$ curve by short segments of constant velocity. (*b*) When the segments are made infinitesimally small, the *x* component of the displacement becomes equal to the area under the $v_x(t)$ curve.

In Section 2.8, I showed that for motion at constant velocity the area under a $v_x(t)$ curve is equal to the *x* component of the object's displacement. Now we see that this holds true for accelerated motion as well. The geometrical relationship among acceleration, velocity change, and displacement is thus

acceleration a_x $\xrightarrow{\text{area under } a_x(t) \text{ curve}}$ velocity change Δv_x from t_i *to* t_f $\xrightarrow{\text{area under } v_x(t) \text{ curve}}$ displacement Δx from t_i *to* t_f.

EXERCISE 3.7 Using calculus to determine displacement

Suppose an object initially at x_i at $t_i = 0$ has a constant acceleration whose *x* component is a_x. Use calculus to show that the *x* component of the velocity and the *x* coordinate at some final instant t_f are given by Eq. 3.10 and Eq. 3.9, respectively.

SOLUTION Because the acceleration is constant, I can pull a_x out of the integration in Eq. 3.27:

$$\Delta v_x = v_{x,f} - v_{x,i} = \int_{t_i}^{t_f} a_x \, dt = a_x \int_{t_i}^{t_f} dt = a_x(t_f - t_i).$$

Substituting $t_i = 0$ and rearranging terms, I obtain Eq. 3.10:

$$v_{x,f} = v_{x,i} + a_x t_f. \checkmark$$

For an arbitrary final instant *t*, I can drop the subscript f. Substituting this expression into Eq. 3.28, I get

$$\Delta x = \int_{t_i}^{t_f} (v_{x,i} + a_x t) dt$$

or, pulling constant terms out of the integration and then carrying out the integration,

$$\Delta x = x_f - x_i = v_{x,i} \int_{t_i}^{t_f} dt + a_x \int_{t_i}^{t_f} t \, dt = v_{x,i} t_f + a_x \left[\tfrac{1}{2} t^2 \right]_{t_i}^{t_f},$$

which yields Eq. 3.9:

$$x_f = x_i + v_{x,i} t_f + \tfrac{1}{2} a_x t_f^2. \checkmark$$

3.14 Take the first and second time derivatives of x_f in Eq. 3.11. What do you notice?

Chapter Summary

Accelerated motion (Sections 3.1, 3.4, 3.5, 3.8)

Concepts If the velocity of an object is changing, the object is **accelerating.** The x component of an object's **average acceleration** is the change in the x component of its velocity divided by the time interval during which this change takes place.

The x component of the object's **instantaneous acceleration** is the x component of its acceleration at any given instant.

A **motion diagram,** which is constructed as described in the Procedure box on page 93, shows the positions of a moving object at equally spaced time intervals.

Quantitative Tools The x component of the **average acceleration** is

$$a_{x,\text{av}} \equiv \frac{\Delta v_x}{\Delta t} = \frac{v_{x,\text{f}} - v_{x,\text{i}}}{t_\text{f} - t_\text{i}}. \tag{3.1}$$

The x component of the **instantaneous acceleration** is

$$a_x = \frac{dv_x}{dt} = \frac{d^2x}{dt^2}. \tag{3.23}$$

The x component of the change in velocity over a time interval is given by

$$\Delta v_x = \int_{t_\text{i}}^{t_\text{f}} a_x(t)dt. \tag{3.27}$$

The x component of the displacement over a time interval is given by

$$\Delta x = \int_{t_\text{i}}^{t_\text{f}} v_x(t)dt. \tag{3.28}$$

Motion with constant acceleration (Section 3.5)

Concepts If an object has constant acceleration, the $v_x(t)$ curve is a straight line that has a nonzero slope and the $a_x(t)$ curve is a horizontal line.

Quantitative Tools If an object moves in the x direction with constant acceleration a_x starting at $t = 0$, with initial velocity $v_{x,\text{i}}$ at initial position x_i, its x coordinate at any instant t is given by

$$x(t) = x_\text{i} + v_{x,\text{i}}t + \tfrac{1}{2}a_x t^2. \tag{3.11}$$

The x component of its instantaneous velocity is given by

$$v_x(t) = v_{x,\text{i}} + a_x t, \tag{3.12}$$

and the x component of its final velocity is given by

$$v_{x,\text{f}}^2 = v_{x,\text{i}}^2 + 2a_x\Delta x. \tag{3.13}$$

Free fall and projectile motion (Sections 3.2, 3.3, 3.6)

Concepts An object subject only to gravity is in **free fall.** All objects in free fall near the surface of Earth have the same acceleration, which is directed downward. We call this acceleration the **acceleration due to gravity** and denote its magnitude by the letter g.

An object that is launched but not self-propelled is in **projectile motion.** Once it is launched, it is in free fall. The path it follows is called its **trajectory.**

Quantitative Tools The magnitude g of the downward acceleration due to gravity is

$$g = |\vec{a}_{\text{free fall}}| = 9.8\ \text{m/s}^2 \quad (\text{near Earth's surface}). \tag{3.14}$$

Motion on an inclined plane (Section 3.7)

Concepts An object moving up or down an inclined plane on which friction is negligible has a constant acceleration that is directed parallel to the surface of the plane and points downward along the surface.

Quantitative Tools When friction is negligible, the x component of acceleration a_x for an object moving on an inclined plane that rises at an angle θ above the horizontal is

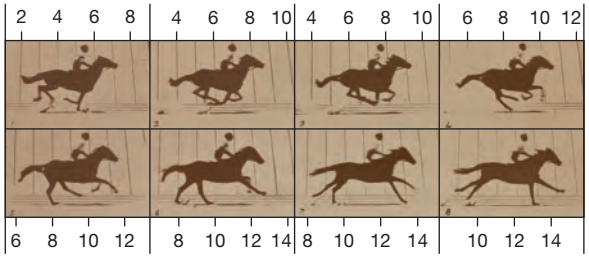
$$a_x = +g\sin\theta \tag{3.20}$$

when the x axis is directed downward along the plane.

Questions and Problems

For instructor-assigned homework, go to Mastering Physics

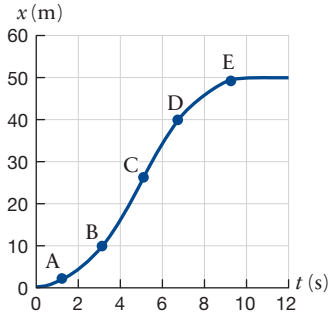
Dots indicate difficulty level of problems: • = easy, •• = intermediate, ••• = hard; CR = context-rich problem.



3.1 Changes in velocity

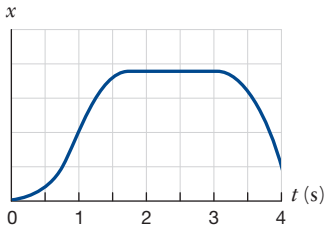
1. Figure P3.1 is based on a multiple-flash photographic sequence of an object moving from left to right on a track, as seen from above. The time intervals between successive flashes are all the same. During which portion(s) of the motion is the object (*a*) speeding up and (*b*) slowing down? Explain how you know in each case. (*c*) How would your answers change if the object were moving from right to left? •

Figure P3.1



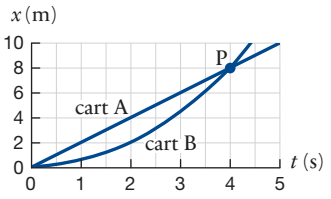
2. A bus is travelling in the northeast direction. What are the directions of its acceleration and velocity (*a*) if it is speeding up and (*b*) if it is slowing down? •
3. Figure P3.3 shows a series of photographs of a racehorse taken in 1877 by Eadweard Muybridge (1830–1904). Muybridge used multiple, equally spaced cameras triggered sequentially at equal time intervals. Is the horse accelerating? How can you tell? •

Figure P3.3



4. Figure P3.4 shows a graph of position as a function of time for an object moving along a horizontal surface. At which of the labeled points is the object speeding up? •

Figure P3.4



5. While you are driving on a highway, a friend in another car passes you at a steady speed. You accelerate at a constant rate to catch up. When you do catch up, are your two cars going the same speed? Use a graph to support your answer. ••
6. The position of a person pacing in a hall is given by the $x(t)$ curve in Figure P3.6. During which time interval(s) is the acceleration (*a*) positive and (*b*) negative? (*c*) Is the acceleration ever zero during the 4-s interval shown? ••

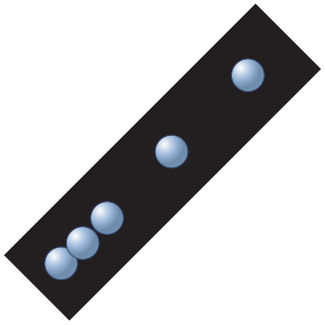
Figure P3.6

7. You are travelling by a bullet train from a point to a distance at 500 km. If the bullet train operates at a uniform speed of 200 km/h, describe your acceleration and inertia at different stages during this trip. ••
8. Figure P3.8 shows the position curves for two carts, A and B, moving on parallel tracks along a horizontal surface. The instant when the two carts are at the same distance from their starting point is indicated by point P. Which cart has the greater acceleration at that instant? ••

Figure P3.8

9. Two cars are headed south on the highway at different speeds. Starting when the faster car pulls alongside the slower car, one of the cars accelerates northward for 5.0 s and the other accelerates southward for 5.0 s. At the end of that 5.0-s interval, the two cars have the same speed. Which car is now ahead? •••

3.2 Acceleration due to gravity



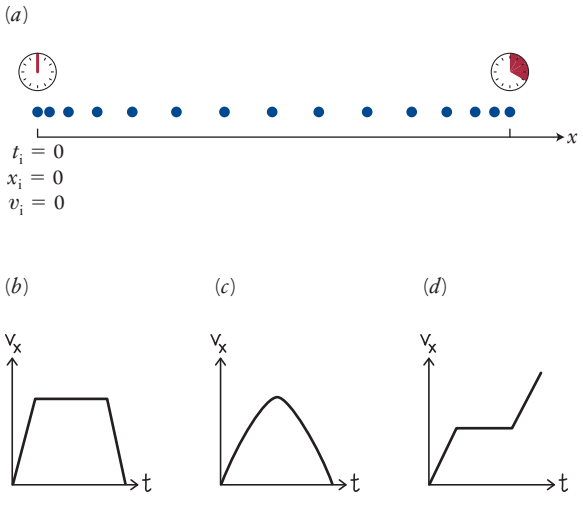
10. A tennis ball was dropped from rest from the window of a multistoried building. Calculate the distance travelled by the ball during one second considering the acceleration due to gravity (g) = 9.8 m/s^2. •
11. (*a*) What is the average speed, over the first 1.0 s of its motion, of a pebble released from rest off a bridge? (*b*) What is the pebble's average speed over the second 1.0 s of its motion? (*c*) What is its average speed during these first 2.0 s of its motion? •

12. You toss a ball to your brother leaning out of a window h m above you, throwing just hard enough for it to reach him. At the same instant, he drops a chocolate bar to you. Prove that the chocolate bar and the ball pass each other $h/4$ m above the ground. ••
13. Suppose that the acceleration due to gravity near Earth's surface was cut in half (to about 5 m/s^2). How would this affect the graphs shown in Figure 3.6, assuming that everything else about the experiment remains the same? Sketch the new curves. ••

3.3 Projectile motion

14. A photographer shows you a multiple-flash photographic sequence of a ball traveling vertically (Figure P3.14). (*a*) If the ball is traveling downward, what is the correct orientation of the picture? (*b*) If the ball is traveling upward, what is the correct orientation of the picture? (*c*) According to the evidence provided by the picture, what is the direction of the ball's acceleration in parts *a* and *b*? •

Figure P3.14



15. A grenade launcher shoots a grenade vertically upward at an initial speed of 120 m/s. What are the vertical distances covered by it after (*a*) 6.0 s, (*b*) 12.0 s? •
16. Two identical balls have the same inertia. One was dropped from a building 20 m high, and another was thrown up from the ground at an initial speed of 26 m/s. After how long will both the balls meet each other in air? •
17. A ball is shot straight up near the Earth's surface. (*a*) Can its velocity be zero while its acceleration is nonzero? (*b*) Is the velocity of the ball the same at any two points, one of which is on the upward trajectory, and one of which is on the downward one? (*c*) Is the speed of the ball the same at any two points, one of which is on the upward trajectory, and one of which is on the downward one? ••
18. How would graphs *c* and *d* in Figure 3.8 be different if the same experiment was conducted on the surface of the Moon, where the acceleration due to gravity is six times less than it is on Earth? ••
19. You throw snowballs down to the sidewalk from the roof of a building. Which technique, if either, makes the snowballs land with more speed: throwing them straight down as hard as you can or throwing them straight up just as hard? (Ignore air resistance.) ••
20. You are standing by a window and see a ball, thrown from below, moving up past the window. The ball is visible for a time interval Δt_{up}. On its way back down the ball passes the window again, remaining visible for a time interval Δt_{down}. Neglecting the effects of air resistance, is $\Delta t_{up} > \Delta t_{down}$, $\Delta t_{up} = \Delta t_{down}$, $\Delta t_{up} < \Delta t_{down}$, or is it impossible to tell without more information? Briefly explain your reasoning, using graphs. ••
21. For an object in free fall, the curve of its velocity as a function of time is a straight line. How would this curve be different when air resistance (which changes with speed) is not negligible? •••
22. When air resistance is ignored, it is straightforward to calculate the travel time interval for a Ping-Pong ball tossed up into the air and caught on its way down because the acceleration can be taken to be a constant 9.8 m/s^2 downward. However, a more accurate result is obtained when air resistance is taken into account. When this is done, is the magnitude of the ball's acceleration greater than, less than, or the same as when air resistance is ignored (*a*) as the ball rises and (*b*) as it falls? (*c*) Do you expect the travel time interval obtained in the more accurate analysis to be greater than, less than, or the same as in the simplified case? •••

3.4 Motion diagrams

23. Draw a motion diagram for a car that starts from rest and accelerates at 4.0 m/s^2 for 10 s. •
24. A car accelerating from rest at constant acceleration reaches a speed of 30 km/h in 5.0 s. Draw a motion diagram for the car. •
25. The motion of a cart moving along a horizontal surface is described by the motion diagram shown in Figure P3.25*a*. The position of the cart is measured every 0.5 s. Asked to suggest a qualitative graph of velocity versus time that would correspond to this motion, three of your classmates draw the graphs shown in Figures P3.25*b*–*d*. Which graph is correct? •

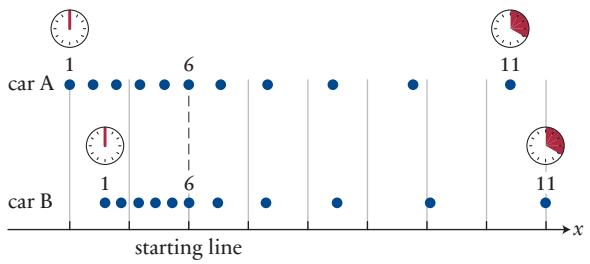


Figure P3.25

26. Draw a motion diagram for a car that starts from rest and accelerates at 5.0 m/s^2 for 6.0 s, then travels with constant speed for 10 s, and then slows to a stop with constant acceleration in 4.0 s. ••

27. A ball you throw straight up has a speed of 30 m/s when it leaves your hand. Draw a motion diagram for the ball up to the instant at which it has a speed of 30 m/s again. Indicate the instant at which the ball reaches its highest position. ●●
28. Figure P3.28 shows motion diagrams for two cars, A and B, beginning a race. The diagrams show the position of each car at instants separated by equal time intervals. Both cars drive up to the starting line and then begin to accelerate. (*a*) Which car has the greater velocity at instant 6? How can you tell? (*b*) Which car has the greater velocity at instant 11? How can you tell? (*c*) Which car has the greater acceleration after instant 6? How can you tell? ●●

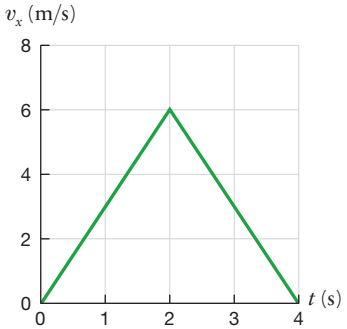

Figure P3.28

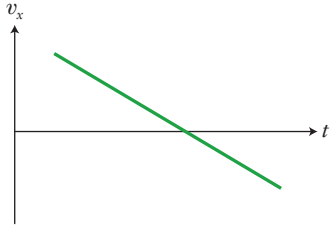
3.5 Motion with constant acceleration



29. A sports car goes from zero to 108 km/hr in 3 seconds. (*a*) What is the acceleration of the car, assuming it is constant? (*b*) How far does it travel during this time period? ●
30. You and your little brother are rolling toy cars back and forth to each other across the floor. He is sitting at $x = 0$, and you are at $x = 4.0$ m. You roll a car toward him, giving it an initial speed of 2.5 m/s. It stops just as it reaches him in 3.0 s. (*a*) In what direction is the car's acceleration? (*b*) What is the car's average acceleration? ●
31. An electron is decelerated from 4×10^6 m/s to zero in 6×10^{-8} s. (*a*) Calculate the distance travelled by the electron in this interval. (*b*) Calculate the average acceleration. ●
32. Figure P3.32 shows a graph of velocity as a function of time for a cart moving along a horizontal surface. When asked to describe the motion that resulted in this graph, a student states, "The cart first moved forward with a constant speed, reached a maximum distance at time 2 seconds, then turned around and came back to its initial position at time 4 seconds." What is your assessment of this comment? ●

Figure P3.32

33. (*a*) How do you determine an object's displacement from a velocity-versus-time graph? (*b*) What distance does a car travel as its speed changes from 0 to 20 m/s in 10 s at constant acceleration? (*c*) The x component of the average velocity of a particle moving along the x axis at constant acceleration is $v_{x,\text{av}} = \frac{1}{2}(v_{x,\text{i}} + v_{x,\text{f}})$. Is the x component of the average velocity also given by this expression when the acceleration is not constant? Use a velocity-versus-time graph to support your answer. ●●
34. On a freeway entrance ramp, you accelerate your 1200-kg car from 5 m/s to 20 m/s over 500 m. Having an open lane, you continue to accelerate at the same (constant) rate for another 500 m. Is your final speed 35 m/s, less than 35 m/s, or greater than 35 m/s? ●●
35. In an introductory physics laboratory, a student drops a steel ball of radius 15 mm, and a device records its position as a function of time. The clock on the device is set so that $t = 0$ at the instant the ball is dropped. What is the ball's displacement (*a*) between 0.15 s and 0.25 s and (*b*) between 0.175 s and 0.275 s? ●●
36. Compare the acceleration of a car that goes from 0 to 100 km/hr in 3 seconds to that of a boulder falling freely near the surface of the Earth. ●●
37. An electron in an old-fashioned television picture tube is accelerated, at a constant rate, from 2.0×10^5 m/s to 1.0×10^7 m/s in a 12-mm-long "electron gun." (*a*) What is the acceleration of the electron? (*b*) What time interval is needed for the electron to travel the length of the gun? ●●
38. In a car moving at constant acceleration, you travel 250 m between the instants at which the speedometer reads 40 km/h and 60 km/h. (*a*) How many seconds does it take you to travel the 250 m? (*b*) What is your acceleration? ●●
39. Based on the $v(t)$ curve in Figure P3.39, explain whether each of these statements is necessarily true for the time interval shown: (*a*) The acceleration is constant. (*b*) The object passes through the position $x = 0$. (*c*) The object has zero velocity at some instant. (*d*) The object is always moving in the same direction. ●●

Figure P3.39

40. In October 1997, Andy Green broke the sound barrier on land in a jet-powered car traveling at 763 mi/h over a 1.0-mi course. As it arrived at the beginning of this measured mile, Green's car had accelerated from rest to 763 mi/h over a 5.0-mi stretch. (*a*) What was Green's average acceleration in that 5.0 mi? (*b*) Calculate the time interval needed for Green to reach his maximum speed. ●●

41. A driver starts a car starts from rest and accelerates to 72 km/hr in 10 seconds. He drives at this speed for another 20 s, and then slows to a stop over a distance of 500 m. (*a*) What is the acceleration of the car during the first and last legs of this trip? (*b*) What is the total travel time? (*c*) What is the total distance of the trip? ••
42. In rush-hour traffic, the car in front of you suddenly puts on the brakes. You apply your brakes 0.50 s later. The accelerations of the two cars are the same. Does the distance between the two cars remain constant, decrease, or increase? ••
43. Two cars are moving at 97 km/h, one behind the other, on a rural road. A deer jumps in front of the lead car, and its driver slams on the brakes and stops. What minimum initial distance between the rear of the lead car and the front of the second car is required if the second car is to stop before hitting the lead car? Assume that the acceleration is the same for both cars and that the driver of the second car begins braking 0.50 s after the lead car begins braking. •••
44. As a physics instructor hurries to the bus stop, her bus passes her, stops ahead, and begins loading passengers. She runs at 6.0 m/s to catch the bus, but the door closes when she's still 8.0 m behind the door, and the bus leaves the stop at a constant acceleration of 2.0 m/s^2. She has missed her bus, but as a physics exercise she keeps running at 6.0 m/s until she draws even with the bus door. (*a*) Calculate Δt from the instant the bus leaves the stop to the instant the instructor draws even with the door. (*b*) At the instant she draws even, how fast is she moving? (*c*) At the instant she draws even, how fast is the bus moving? (*d*) Plot $v(t)$ for the bus and the instructor. (*e*) Plot $x(t)$ for the bus and the instructor. •••
45. The day after the incident described in Problem 44, the instructor finds herself in the same situation. This time, she tries a harder physics exercise. She keeps running at a constant 6.0 m/s after drawing even with the bus door and pulls ahead for a while, but the accelerating bus soon overtakes her. By what maximum distance does she get ahead of the door? •••

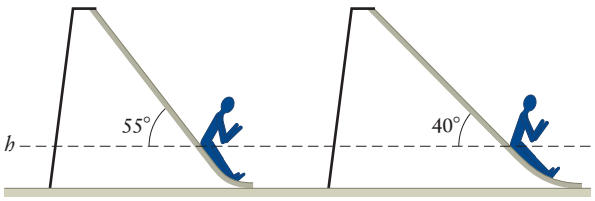
3.6 Free-fall equations

46. A ball was dropped from the top of the Eiffel Tower, 300 m high. (*a*) Calculate the time taken by the ball to reach the ground (*b*) What is the final speed of the ball when it hits the ground? •
47. An object takes 3 s to fall from the top of the building to the ground. Calculate what time will be required by the object to fall from the same height on Moon's surface ($g_{moon} = 1.625$ m/s^2) •
48. A mortar-style fireworks shell is launched upward at 35 m/s. Draw a motion diagram showing the position of the shell and its velocity vector at $t = 0$, 1 s, 2 s, 3 s, and 4 s, and draw a graph of $x(t)$. •
49. The distance a ball thrown upward and released at $t = 0$ travels between $t = 3.0$ s and $t = 4.0$ s is the same as the distance the ball travels between $t = 2.0$ s and $t = 3.0$ s. How is this possible? ••
50. You toss a ball straight up, and it reaches a maximum height h above the launch position. If you want to double the length of the time interval during which the ball stays in the air above the launch position, to what maximum height do you have to throw it? ••
51. A ball is thrown vertically up with a speed 10 m/s, caught by a boy leaning out of a window in 4 seconds. (*a*) Calculate the height of the window from the ground (*b*) What is the final speed of the ball before it is caught? ••
52. A snowshoer falls off a ridge into a snow bank 3.6 m below and penetrates 0.80 m into the snow before stopping. What is her average acceleration in the snow bank? ••
53. You are on the second floor of a building under construction, laying bricks of dimensions 63 mm × 89 mm × 170 mm. At your command, a coworker below tosses bricks up to you, and you catch them when they have risen 5.0 m above the launch point. He tosses the bricks consistently so that, if untouched by you, they would rise to a maximum height of 6.0 m above the launch point. (*a*) Soon you both get good at this, and you know exactly how many seconds after you yell "3, 2, 1, throw!" you should reach out and catch the brick on its way up. What is the length of this time interval if your coworker throws without delay at your command? (*b*) If you miss a brick on the way up, during what remaining time interval can you reach out and catch the brick on its way down? ••
54. A rocket ignited on the ground travels vertically upward with an acceleration of magnitude $4g$. A spent rocket stage detaches from the payload after the rocket has accelerated for 5.0 s. With what speed does the spent stage hit the ground? ••
55. Show that the distances traveled by a falling rock in successive 1-s intervals after release are in the ratio 1:3:5:7. . . . ••
56. A hot-air balloon takes off from the ground traveling vertically with a constant upward acceleration of magnitude $g/4$. After time interval Δt, a crew member releases a ballast sandbag from the basket attached to the balloon. How many seconds does it take the sandbag to reach the ground? •••
57. A rock dropped from the top of a building takes 0.50 s to fall the last 50% of the distance from the top to the ground. How tall is the building? •••
58. A hot-air balloon of diameter 10 m rises vertically at a constant speed of 12 m/s. A passenger accidentally drops his camera from the railing of the basket when it is 18 m above the ground. If the balloon continues to rise at the same speed, how high is the railing when the camera hits the ground? •••
59. A ball tossed vertically upward from the ground next to a building passes the bottom of a window 1.8 s after being tossed and passes the top of the window 0.20 s later. The window is 2.0 m high from top to bottom. (*a*) What was the ball's initial velocity? (*b*) How far is the bottom of the window from the launch position? (*c*) How high does the ball rise above the launch position? •••

3.7 Inclined planes

60. In a children's park, a boy uses a slide with inclination 50° with respect to the ground. Ignoring friction, calculate the magnitude of the acceleration of the boy. •
61. A box slides from rest down a 2-m long 20° incline. How long does it take the box to reach the bottom of the incline? •

62. Imagine that in his experiment with balls rolling down an inclined plane, Galileo had considered balls that were given an initial speed. Would he have reached different conclusions about the ratio of distance and square of time? •



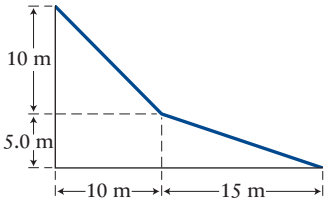
63. A worker releases boxes at the top of a ramp. From the bottom of the ramp the boxes slide 10 m across the floor to a barrier wall. If the ramp is at an elevation angle of 20°, how long must the ramp be if the boxes are to reach the wall 2.0 s after leaving the ramp? Ignore friction. ••

64. A man steps outside one winter day to go to work. His icy driveway is 8.0 m long from top to mailbox, and it slopes downward at 20° from the horizontal. He sets his briefcase on the ice at the top while opening the garage, and the briefcase slides down the driveway. Ignore friction. (*a*) What is its acceleration? (*b*) How many seconds does it take to get halfway to the mailbox? (*c*) How many seconds does it take to reach the mailbox? (*d*) What is its speed at the instant it reaches the mailbox? ••

65. You and a friend ride what are billed as the "world's longest slides" at a county fair. Your slide is 100 m long, and your trip takes 10 s, including any effect of friction. Your friend chooses a taller, 150-m-long slide made from the same material as yours and with the same angle of incline. Ignore friction. (*a*) What is the magnitude of your acceleration down the slide? (*b*) What is the magnitude of your friend's acceleration down the slide? (*c*) How many seconds does it take your friend to get to the bottom? (*d*) What is your speed when you hit the bottom? (*e*) What is your friend's speed when she reaches the bottom? ••

66. Two children at a playground slide from rest down slides that are of equal height but are inclined at different angles with respect to the horizontal (Figure P3.66). Ignoring friction, at height h above the ground, which child has (*a*) the greater acceleration and (*b*) the higher speed? ••

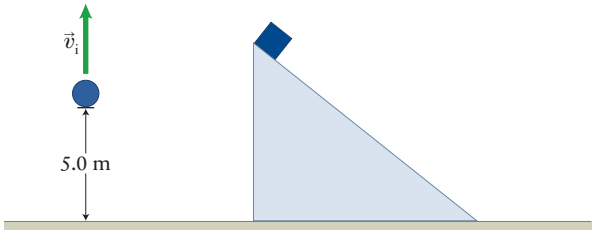
Figure P3.66



67. You are playing air hockey with a friend. The puck is sitting at rest in his goal when he suddenly lifts his end of the table by 0.50 m. The puck slides down the tilted surface into your goal, 2.4 m away. Ignore friction. (*a*) How many seconds does it take the puck to reach your goal? (*b*) With what speed does the puck hit your goal? ••

68. A block has an initial speed of 6.0 m/s up an inclined plane that makes an angle of 37° with the horizontal. Ignoring friction, what is the block's speed after it has traveled 2.0 m? ••

69. A box is at the lower end of a very slippery ramp of length ℓ that makes a nonzero angle θ with the horizontal. A worker wants to give the box a quick shove so that it reaches the top of the ramp. (*a*) How fast must the box be going after the shove for it to reach its goal? (Ignore the distance traveled while the shove is executed.) (*b*) What is its speed halfway up the ramp? ••



70. A skier is at the top of a run that consists of two slopes having different inclines (Figure P3.70). The skier lets go, beginning the run with essentially zero speed. Ignoring friction, what are (*a*) his speed at the end of the lower slope and (*b*) his average acceleration over the entire run? ••

Figure P3.70

71. A ball is projected vertically upward from an initial position 5.0 m above the ground (Figure P3.71). At the same instant, a cube is released from rest down an ice-covered incline, from a height not necessarily equal to 5.0 m. The two objects reach the ground at the same instant, and both have a final speed of 15 m/s. What is the angle of the incline? •••

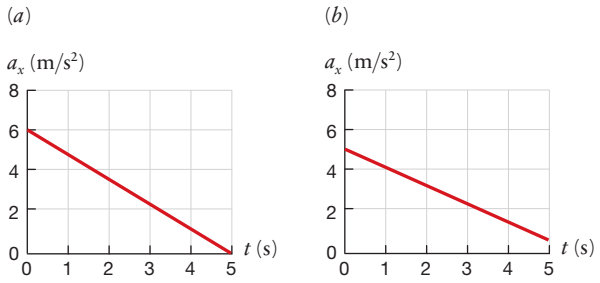
Figure P3.71

72. You hold a puck at the top of an ice-covered ramp inclined at 60° with respect to the vertical. Your friend stands nearby on level ground and holds a ball at the same height h above ground as the puck. If the puck and the ball are released from rest at the same instant, what is the ratio of the time interval it takes the ball to reach the ground to the time interval it takes the puck to reach the end of the ramp? •••

73. A child on a sled slides down an icy slope, starting at a speed of 2.5 m/s. The slope makes a 15° angle with the horizontal. After sliding 10 m down the slope, the child enters a flat, slushy region, in which she slides for 2.0 s with a constant negative acceleration of $-1.5\ \text{m/s}^2$ with respect to her direction of motion. She then slides up another icy slope that makes a 20° angle with the horizontal. How far up the second slope does she slide? •••

3.8 Instantaneous acceleration

74. You throw a ball straight up with an initial speed of 10 m/s. (*a*) What is the ball's instantaneous acceleration at instant t_1, just after it leaves your hand; at instant t_2, the top of its trajectory; and at instant t_3, just before it hits the ground? (*b*) What is its average acceleration for the upward portion of its journey (t_1 to t_2) and for the entire trip (t_1 to t_3)? •



75. The equation of motion of a particle on xy plane as a function of time is given by

$$\vec{x} = 4bt^3\hat{i} + 48t + 20$$

Compute the particle's acceleration as a function time at 3 s. Here, $b = 4.5\ \text{m/s}^3$ •

76. Figure P3.76 shows graphs of the x component of acceleration as a function of time for two different carts rolling along a flat horizontal table. In which case is the change in the x component of velocity greater over the time interval shown? •

Figure P3.76

77. The position of a cart on a low-friction track can be represented by the equation $x(t) = b + ct + et^2$, where $b = 4.00$ m, $c = 6.00$ m/s, and $e = 0.200\ \text{m/s}^2$. (*a*) Is the cart accelerating? If so, is the acceleration constant? (*b*) What is the average velocity between $t_i = 0.200$ s and $t_f = 0.400$ s? (*c*) What is the velocity at $t = 0.200$ s and at $t = 0.400$ s? (*d*) What is the average acceleration between $t_i = 0.200$ s and $t_f = 0.400$ s? (*e*) What is the acceleration at $t = 0.200$ s and at $t = 0.400$ s? ••

78. A particle moves in the x direction according to the equation $x(t) = a + bt + ct^2$, where $a = 2.0$ m, $b = 0.5$ m/s, and $c = -0.4\ \text{m/s}^2$. ••

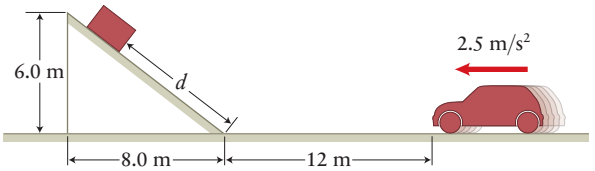
(*a*) What is the particle's instantaneous velocity and instantaneous acceleration at $t = 10$ s?

(*b*) What is its average velocity and average acceleration between $t = 5$ s and $t = 10$ s?

79. The acceleration of a particle can be represented by the equation $a(t) = t^2$. The particle begins accelerating from rest at $t = 0$.

(*a*) What is its acceleration at $t = 2$ s?

(*b*) What is the velocity at $t = 2$ s?



(*c*) What is the average acceleration between $t = 0$ and $t = 2$ s?

(*d*) What is the distance traveled between $t = 0$ and $t = 2$ s? ••

80. The acceleration of a particular car during braking has magnitude bt, where t is the time in seconds from the instant the car begins braking, and $b = 2.0\ \text{m/s}^3$. If the car has an initial speed of 50 m/s, how far does it travel before it stops? ••

81. A car is 12 m from the bottom of a ramp that is 8.0 m long at its base and 6.0 m high (Figure P3.81). The car moves from rest toward the ramp with an acceleration of magnitude $2.5\ \text{m/s}^2$. At some instant after the car begins moving, a crate is released from rest from some position along the ramp. The crate and car reach the bottom of the ramp at the same instant and at the same speed. (*a*) At what distance d up the ramp was the crate released? (*b*) How many seconds after the car started was the crate released? •••

Figure P3.81

82. In a laboratory experiment, a sphere of diameter 8.0 mm is released from rest at $t = 0$ at the surface of honey in a jar, and the sphere's downward speed v when it travels in the honey is found to be given by $v = v_{max}(1 - e^{-t/\tau})$, where $v_{max} = 0.040$ m/s and $\tau = 0.50$ s. (*a*) Obtain an expression for $a(t)$. (*b*) Draw graphs for $v(t)$ and $a(t)$ for the time interval 0 to 2.0 s. (*c*) Obtain an expression for $x(t)$, choosing the positive x axis as downward, and draw the graph for this function. (*d*) Use your $x(t)$ graph to determine the time interval needed for the sphere to reach the bottom of the container if the surface of the honey is 0.10 m above the bottom of the jar. •••

83. A video recording of a moving object shows the object moving up and down with a velocity given by $v_x(t) = v_{max}\cos(\omega t)$, where $v_{max} = 1.20$ m/s and $\omega = 0.15\text{s}^{-1}$ and where the positive x direction is upward. (*a*) Derive an expression for $a(t)$, the object's acceleration as a function of time. (*b*) If the object's position at $t = 0$ is $x(0) = 0$, derive an expression for $x(t)$, its position as a function of time. •••

Additional Problems

84. The equation of motion of a particle travelling along the x-axis is given as

$$x(t) = 3bt^3 + 4ct^2 + dt$$

where $b = 0.4\ \text{m/s}^3$, $c = 0.5\ \text{m/s}^2$ and $d = 50$ m/s.

(*a*) Calculate the particle's acceleration $t = 20$ s.

(*b*) What is the distance travelled at $t = 5$ s? •

85. It takes you 7.0 m to brake to a panic stop from a speed of 9.0 m/s. Using the same acceleration, how far do you go as you brake to a panic stop from a speed of 27 m/s? •

86. A person standing on a building ledge throws a ball vertically from a launch position 45 m above the ground. If it takes 2.0 s for the ball to hit the ground, (*a*) with what initial speed was the ball thrown and (*b*) in which direction was it thrown? ••

87. A bullet fired straight through a board 0.10 m thick strikes the board with a speed of 480 m/s, has constant acceleration through the board, and emerges with a speed of 320 m/s. (*a*) What is the component of the acceleration in the direction of the bullet's motion? (*b*) What is the time interval between the instant the bullet strikes the front face of the board and the instant it exits the back face? (*c*) Assuming the average acceleration you calculated in part *a*, what minimum thickness must the board have in order to stop the bullet? ••

88. During a blackout, you are trapped in a tall building. You want to call rescuers on your cell phone, but you can't remember which floor you're on. You pry open the doors to the elevator shaft, drop your keys down the shaft, and hear them hit bottom at ground level 3.27 s later. (*a*) Making a simple calculation and remembering that the ground floor is numbered floor 1, you determine

which floor you're on. What floor is that? (*b*) Before you make the phone call, however, you realize you've forgotten that the sound of the impact at the bottom travels up the shaft at 340 m/s, and so you redo your calculation. What floor number do you tell the rescuers? ●●

89. Starting from rest, a motorcycle moves with constant acceleration along a highway entrance ramp 0.22 km long. The motorcycle enters the traffic stream on the highway 14.0 s later at 31.0 m/s. (*a*) What is the magnitude of the acceleration along the ramp? (*b*) How fast is the motorcycle moving 9.5 s after it begins to accelerate? (*c*) How far along the ramp is the motorcycle 9.5 s after it begins to accelerate? ●●

90. Hold a dollar bill with its short sides parallel to the floor, and have a friend hold the thumb and forefinger of one hand on either side of the bottom edge, with the thumb and finger about 20 mm apart. Offer your friend the following deal: He can keep the dollar if he can catch it between his thumb and finger after you release it. Most people fail to catch the bill. Use this information (and your measurement of the length of the long side of a dollar bill) to calculate a typical minimum reaction time. ●●

91. A bullet is fired directly upward and reaches a height of 45 m. (*a*) What is the muzzle speed of the gun? (*b*) How much time does it take the bullet to reach its maximum height? ●●

92. A rock dropped from the top of a building travels 30 m in the last second before it hits the ground. How high is the building? ●●

93. A ball launched directly upward from the ground at an initial speed of 24.5 m/s hits the ground 5.0 s later. What are (*a*) the ball's upward position 1.0, 2.0, 3.0, and 4.0 s after launch; (*b*) its upward velocity 1.0, 2.0, 3.0 and 4.0 s after launch; (*c*) its average velocity while it is in the air; and (*d*) its average speed for the entire trip? ●●

94. After landing on Mars, you drop a marker from the door of your landing module and observe that it takes 2.1 s to fall to the ground. When you dropped the marker from the module door on Earth, it took 1.3 s to hit the ground. What is the magnitude of the acceleration due to gravity near the surface of Mars? ●●

95. A very elastic rubber ball dropped from a height of 2.1 m rebounds to 88% of its original height. If the ball is in contact with the floor for 0.013 s, what is its average acceleration during that interval? ●●

96. A scout wants to determine the depth of a dark well. She drops a pebble and hears a splash 5 seconds later. If the speed of sound in air is 343 m/s, (*a*) how long does it take the pebble to reach the water? (*b*) How deep is the well? ●●

97. An elevator cable breaks, and the elevator car falls four floors (from rest) before the emergency brakes kick in. If the car falls one more floor before it stops, what is its average acceleration during braking? ●●

98. A car initially traveling with velocity $\vec{v}_i$ slows down at constant acceleration and stops. (*a*) Sketch a graph of $v_x(x)$, the car's x component of velocity as a function of *position*. (*b*) If the car travels a distance ℓ during this braking, after what displacement does it have half its original speed? ●●

99. A theorist has predicted a form of matter, called X-matter, that is gravitationally attracted to other X-matter but gravitationally *repels* ordinary matter. On a planet made of X-matter, an object made of ordinary matter would feel an "antigravitational" acceleration, pointing upward, away from the planet's surface. Such an object released near the ground would move not in free-fall motion but rather in "free-rise motion." Suppose that on this planet, a projectile launched downward from a cliff at an initial speed of 20 m/s is observed 10 s later moving upward at 40 m/s. (*a*) What is the free-rise acceleration on this planet? (*b*) At what instant after launch is the projectile's speed zero? ●●

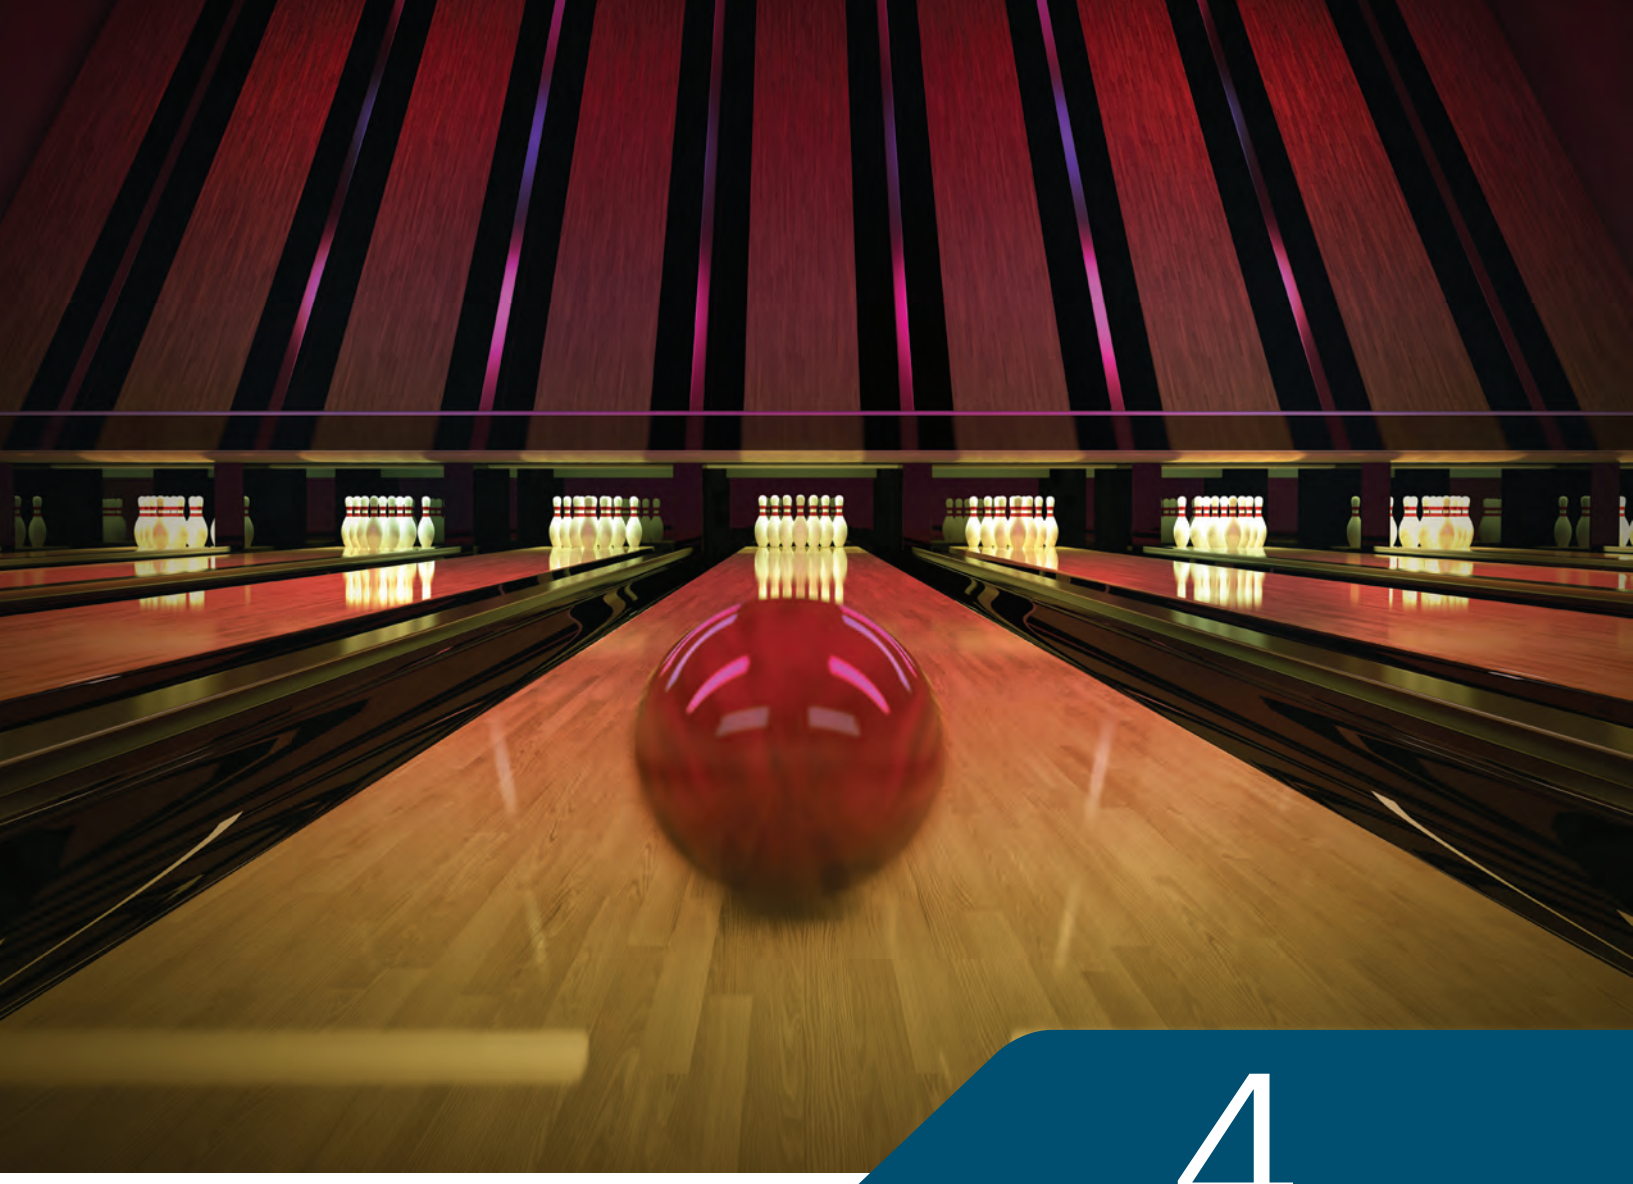
100. A rocket is fired vertically up at an average acceleration of 2 m/s^2. Taking $t = 0$ at lift-off, (*a*) what is the velocity of the rocket at $t = 1$ min? (*b*) What is its velocity at $t = 2$ min? (*c*) What is the altitude after 30 seconds? ●●

101. From a promontory overhanging a lake, you throw a stone that enters the water vertically at 15.0 m/s. You hear the splash 2.68 s after you release the stone. Given that the speed of sound in air is 340 m/s: (*a*) What was the stone's initial speed? (*b*) Did you throw the stone down or up? (*c*) From what height above the lake surface did you release the stone? ●●

102. Your state's *Driver Handbook* says, "When the vehicle ahead of you passes a certain point such as a sign, count 'one-thousand-one, one-thousand-two, one-thousand-three.' This takes about three seconds. If you pass the same point before you finish counting, you are following too closely." In your car, you are following a truck on the highway, both of you moving at 100 km/h. You are keeping a 3.0-s gap between your front bumper and the rear of the truck. Suddenly a large box appears on the road beneath the rear of the truck. Apparently the truck's axles were tall enough to allow it to pass right over the object, but yours are not! It takes you 0.75 s to react and hit your brakes. (*a*) What is the minimum constant acceleration required if you are not to hit the box? (*b*) What would your answer be if you were keeping a 2.0-s gap between your car and the truck, as is sometimes recommended as safe, under optimal driving conditions, for alert, experienced drivers with good reflexes? Compare and comment on your answers in parts *a* and *b*. ●●

103. A falling rock hits the ground at a speed of 16 m/s. How many seconds were needed for the rock to fall the last 12 m? ●●

104. You want to determine whether a tall tree will fit onto your 75-m-long logging trailer after you cut it down. You throw a rock straight up with a speed great enough that the rock just reaches the top of the tree, releasing the rock 2.0 m above the ground. You observe that the time interval from the instant you release the rock to the moment it hits the ground is 5.0 s. How tall is the tree? ●●● CR



105. Your cousin is always bragging about how high his model rockets go, so you go shopping. None of the brands specify altitude, but you do find three models in your price range with comparable technical information. "Cloudscraper" promises a 3.3-s fuel burn time and 2.9*g* vertical acceleration. "Stratosphere" offers 3.0 s at 3.2*g*, and "Astronaut" claims 2.7 s at 3.6*g*. Which will go highest? ●●● CR

106. You are enjoying a coffee break with your cousin in her highway patrol car when a sports car speeds by at 135 km/h. Your cousin tells you to hold her coffee as she starts the car, and she offers to bet you ten dollars that she can catch the speeder before he reaches the state line. You know that the state line is 2.0 km away along the straight and level highway, and you have read that police cruisers can reach a top speed of 210 km/h within 15 s from a resting start. As the car begins to move, you realize that 5.0 s has already elapsed and that you must decide soon. Should you take the bet? ●●● CR

107. At the drag races, three physics students note that the winning dragster in one category has a speed of 215 mi/h at the end of its quarter-mile run. The run takes 6.30 s, and the car, initially at rest, starts exactly when the timing clock starts. Using these data, and with Chapter 3 as their guide, the students calculate the magnitude of the dragster's acceleration. Although their physics instructor verifies that they have made no numerical errors, the students get three different values for the acceleration. (*a*) What are those values? (*b*) One of the students notices an interesting connection among the three values they obtained. What is that connection? (*c*) Is there a reasonable explanation for the discrepancies found in part *a*? ●●●

108. You are touring a distant planet on which the magnitude of the free-fall acceleration is 65.0% of what it is on Earth. For a little excitement, you jump off a precipice 500 m above the planet's surface. After 5.00 s of free fall, you ignite the jet-pack on your back, changing your acceleration to some new, constant value for the remainder of the fall. You reach the ground 26.0 s after igniting the jet-pack. At what speed do you hit the ground? ●●●

109. A classmate leaves a message on your voice mail betting that you cannot throw a stone high enough so it lands on the roof of a 20-m-high building. As you stare out of your window pondering whether to accept the challenge, the well in the courtyard suddenly gives you an idea. You drop a stone into the well and note that you hear a splash 4.0 s later. You repeat the experiment with another stone, but this time you throw the stone down as fast as you can. This time the splash comes 3.0 s after the stone leaves your hand. You carry out a quick calculation and then you call back your friend. Should you take the bet? ●●● CR

QUANTITATIVE TOOLS

4.5 Inertial standard
4.6 Momentum
4.7 Isolated systems
4.8 Conservation of momentum

In the preceding two chapters, we developed a mathematical framework for describing motion along a straight line. In this chapter, we continue our study of motion by investigating inertia, a property of objects that affects their motion. The experiments we carry out in studying inertia lead us to discover one of the most fundamental laws in physics—conservation of momentum.

4.1 Friction

Picture a block of wood sitting motionless on a smooth wooden surface. If you give the block a shove, it slides some distance but eventually comes to rest. Depending on the smoothness of the block and the smoothness of the wooden surface, this stopping may happen sooner or it may happen later. If the two surfaces in contact are very smooth and slippery, the block slides for a longer time interval than if the surfaces are rough or sticky. This you know from everyday experience: A hockey puck slides easily on ice but not on a rough road.

Figure 4.1 shows how the velocity of a wooden block decreases on three different surfaces. The slowing down is due to *friction*—the resistance to motion that one surface or object encounters when moving over another. Notice that, during the interval covered by the velocity-versus-time graph, the velocity decrease as the block slides over ice is hardly observable. The block slides easily over ice because there is very little friction between the two surfaces. The effect of friction is to bring two objects to rest with respect to each other—in this case the wooden block and the surface it is sliding on. The less friction there is, the longer it takes for the block to come to rest.

Figure 4.1 Velocity-versus-time graph for a wooden block sliding on three different surfaces. The rougher the surface, the more quickly the velocity decreases.

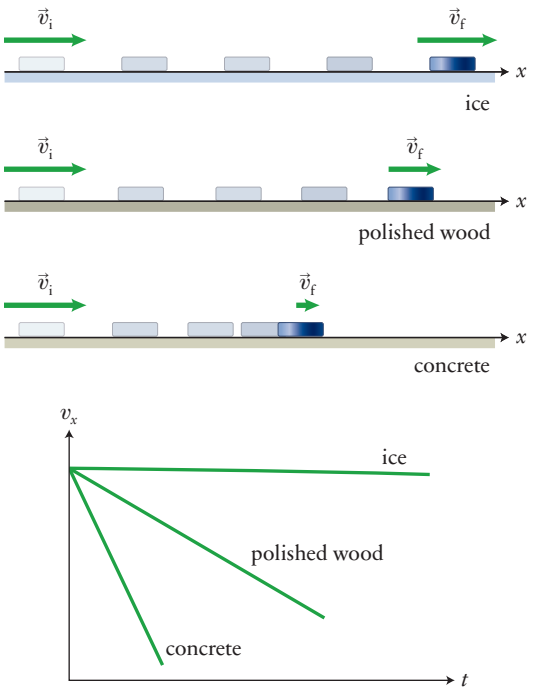

Figure 4.2 Low-friction track and carts used in the experiments described in this chapter.

You may wonder whether it is possible to make surfaces that have no friction at all, such that an object, once given a shove, continues to glide forever. There is no totally frictionless surface over which objects slide forever, but there are ways to minimize friction. You can, for instance, float an object on a cushion of air. This is most easily accomplished with a low-friction track—a track whose surface is dotted with little holes through which pressurized air blows. The air serves as a cushion on which a conveniently shaped object can float, with friction between the object and the track all but eliminated. Alternatively, one can use wheeled carts with low-friction bearings on an ordinary track. **Figure 4.2** shows low-friction carts you may have encountered in your lab or class. Although there is still some friction both for low-friction tracks and for the track shown in Figure 4.2, this friction is so small that it can be ignored during an experiment. For example, if the track in Figure 4.2 is horizontal, carts move along its length without slowing down appreciably. In other words:

In the absence of friction, objects moving along a horizontal track keep moving without slowing down.

Another advantage of using such carts is that the track constrains the motion to being along a straight line. We can then use a high-speed camera to record the cart's position at various instants, and from that information determine its speed and acceleration.

CONCEPTS

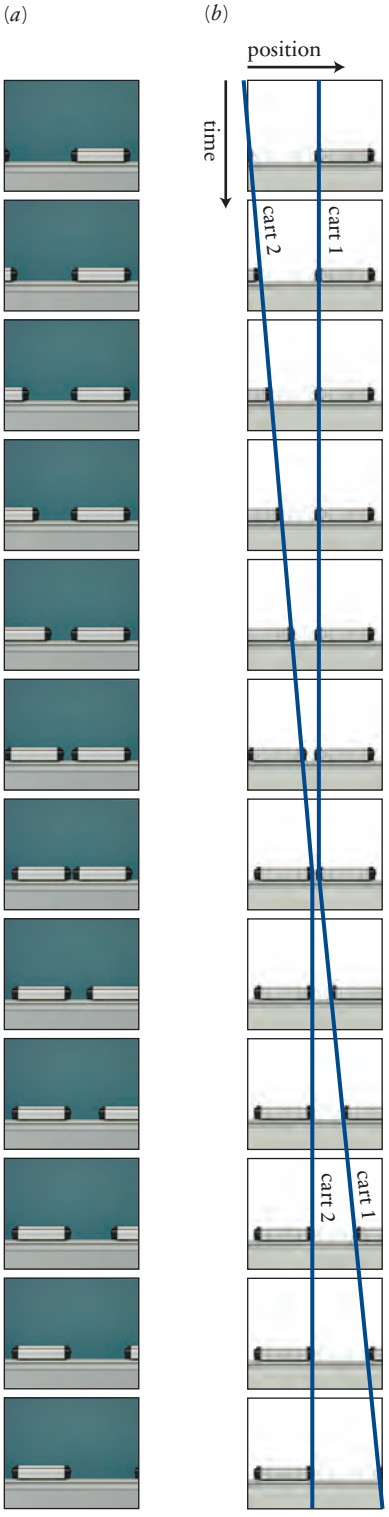
4.1 (*a*) Are the accelerations of the motions shown in Figure 4.1 constant? (*b*) For which surface is the acceleration largest in magnitude?

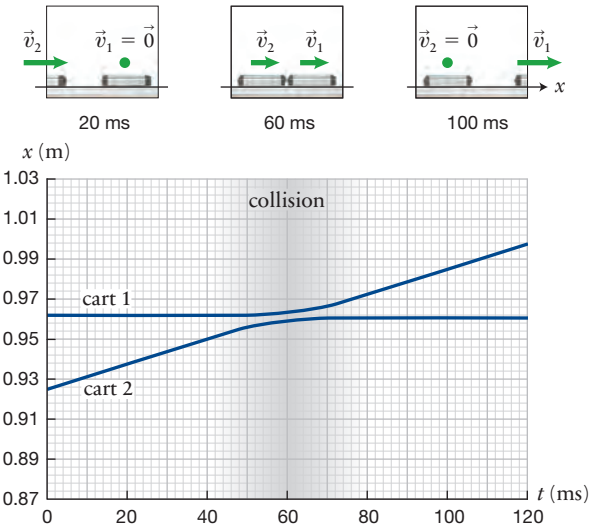
4.2 Inertia

We can discover one of the most fundamental principles of physics by studying how the velocities of two low-friction carts change when the carts collide. Let's first see what happens with two identical carts. We call these *standard carts* because we'll use them as a standard against which to compare the motion of other carts. First we put one standard cart on the low-friction track and make sure it doesn't move. Next we place the second cart on the track some distance from the first one and give the second cart a shove toward the first. The two carts collide, and the collision alters the velocities of both.

Figure 4.3 shows a high-speed video sequence of such a collision. Cart 1 is initially at rest, and consequently its position doesn't change in the first seven frames. Cart 2 approaches cart 1 from the left and collides with it 60 ms after the beginning of the video sequence. The collision causes cart 1 to move to the right and cart 2 to stop dead in its tracks (or, rather, track).

Figure 4.3 (*a*) Two identical carts collide on a low-friction track. The length of track visible in each frame is 0.40 m. Cart 1 is initially at rest; cart 2 collides with it in the middle of the sequence. (*b*) Two curves, one marking the position of the rear of cart 1 and the other marking the position of the front of cart 2, superimposed on the video frames.





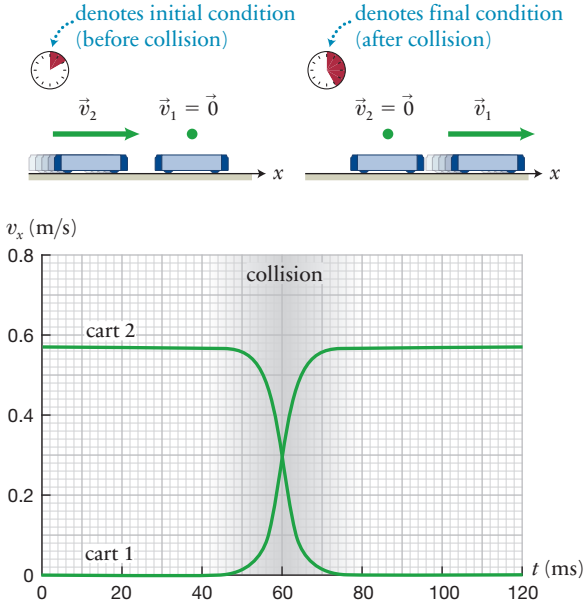


Figure 4.4 Position-versus-time graph for the two carts in Figure 4.3. The curves correspond to the curves of Figure 4.3*b*. All 120 original frames in the sequence were used to obtain this graph.

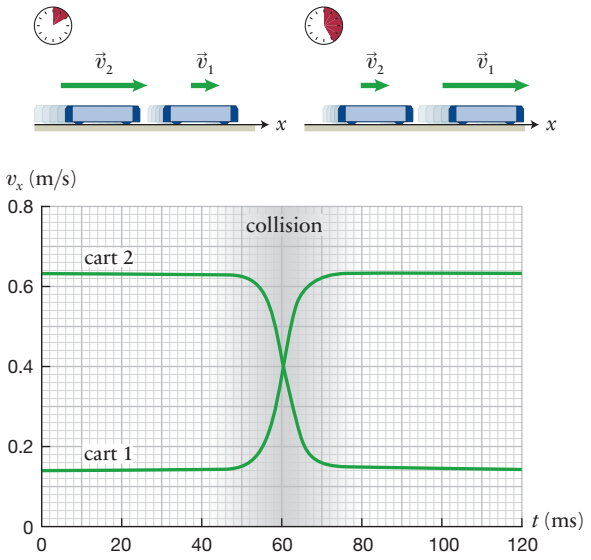
Measuring the positions of the two carts at various instants gives us the $x(t)$ curves shown in **Figure 4.4**, where the shaded region shows the time interval during which the collision took place. Although the collision appears "instantaneous" to any observer, it takes about 10 ms for the motion of the carts to adjust.

Figure 4.5, which shows the velocities of the two carts, tells us that initially the velocities are constant: 0 for

Figure 4.5 Velocity-versus-time graph for the carts of Figure 4.3 before and after the collision. Before the collision, cart 1 is at rest; after the collision, cart 2 is at rest and cart 1 moves at the initial velocity of cart 2.

CONCEPTS

Figure 4.6 Velocity-versus-time graph for two identical carts before and after a collision on a low-friction track. Both carts are initially moving in the same direction.



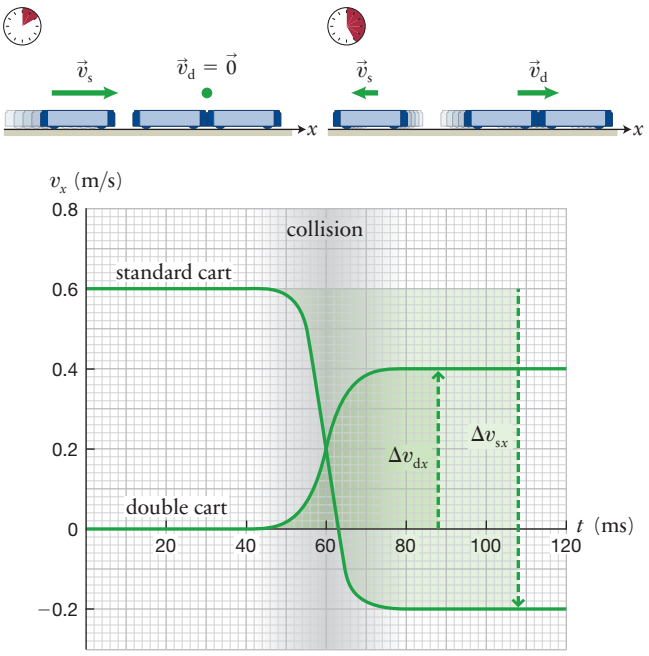


Figure 4.7 Velocity-versus-time graph for a standard cart and a double cart before and after the two collide on a low-friction track. The collision sets the double cart into motion and reverses the direction of travel of the standard cart.

cart 1 and about +0.58 m/s (the plus sign indicating motion to the right) for cart 2. After the collision, the velocities are interchanged: Cart 1 now moves to the right at +0.58 m/s, and cart 2 has come to a complete stop. We can also see this interchanging of velocities in Figures 4.3 and 4.4, where the slopes of the two $x(t)$ curves are interchanged after the collision.

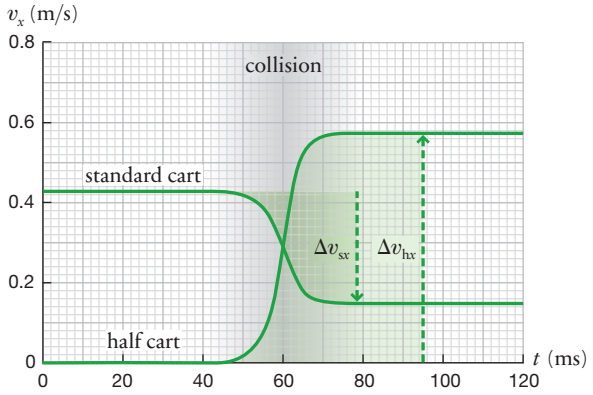
We can repeat the experiment, this time giving cart 2 a harder shove, and then repeat it again, this third time giving cart 2 just a gentle nudge. What we discover is that, *no matter what the initial velocity of cart 2 is*, the collision always interchanges the two velocities.

Further experiments show that it is not necessary that cart 1 be initially at rest. **Figure 4.6** shows what happens when both carts are moving in the same direction at the instant of collision: Once again the collision interchanges the two velocities.

4.2 What is the change in velocity of (*a*) cart 1 and (*b*) cart 2 in Figure 4.6? (*c*) What do you notice about your two answers?

You can repeat this experiment with many different initial velocities, with the carts moving in the same direction or in opposite directions, and you will always observe that the collision interchanges the velocities of the carts. Moreover, Checkpoint 4.2 shows that, if the velocity of one cart increases by a certain amount as a result of the collision, then the velocity of the other cart decreases by exactly the same amount.

To determine whether the volume of material that makes up each cart affects the motion, let's fasten two standard carts together so that the size of this unit is twice the size of the other cart we are going to use, which we continue to call the standard cart. With this double cart at rest on the track, we shove the standard cart toward it at a speed of 0.60 m/s. This time the moving (standard) cart does not come to a complete stop; instead, the collision reverses its direction of travel, so that after the collision it moves to the left with a speed of 0.2 m/s, as **Figure 4.7** shows. After the collision, the initially stationary double cart, being more difficult to set in motion than the single standard cart, moves to the right, as before, but now its speed is lower than in the earlier experiments (0.40 m/s versus about 0.60 m/s). This result makes sense because we already know from experience that more massive objects are harder to set into motion than less massive ones (other than by the force of gravity)—it's easier to throw a small stone than a large boulder.



The x component of the velocity of the double cart changed by $\Delta v_{dx} = +0.40\ \text{m/s} - 0 = +0.40\ \text{m/s}$, and the x component of the velocity of the standard cart changed by $\Delta v_{sx} = -0.20\ \text{m/s} - (+0.60\ \text{m/s}) = -0.80\ \text{m/s}$.* The magnitude of the double cart's velocity change, $|\Delta v_{dx}| = 0.40\ \text{m/s}$, is half that of the standard cart, $|\Delta v_{sx}| = 0.80\ \text{m/s}$.

We can repeat this experiment and vary the initial speeds and directions of motion, but we would continue

*Because we must keep track of the changes in velocity of two colliding objects, we need an additional subscript. For example, $\Delta v_{dx} = v_{dx,f} - v_{dx,i}$ is the change in velocity for the double cart. The final subscript, separated by a comma, designates the instant: f for final and i for initial. The middle subscript indicates that we are dealing with the x component. The first subscript designates the object (d for double cart).

CONCEPTS

Figure 4.8 Velocity-versus-time graph for a standard cart and a half cart before and after the two collide on a low-friction track.

to observe that *no matter how the carts move (or do not move) initially, the magnitude of the velocity change of the double cart is always half that of the standard cart.* Also, the two velocity changes are always in opposite directions, which means the x component of the velocity of one cart increases and that of the other cart decreases.

Now let us repeat the collision once again, this time with the original cart 1 cut in half so that it is half the size of the other cart we'll be using. With the half cart at rest on the track, we push a standard cart toward it. As **Figure 4.8** shows, the magnitude of the velocity change of the half cart is twice the magnitude of the velocity change of the standard cart: $|\Delta v_{hx}| = 0.58$ m/s and $|\Delta v_{sx}| = 0.29$ m/s.

A pattern is developing here: For a group of objects all made of the same material, the motion of larger objects is harder to change than the motion of smaller objects. The larger objects put up more resistance when we try to change their velocity. This tendency of an object to resist a change in its velocity is called **inertia.**

Inertia is a measure of an object's tendency to resist any change in its velocity.

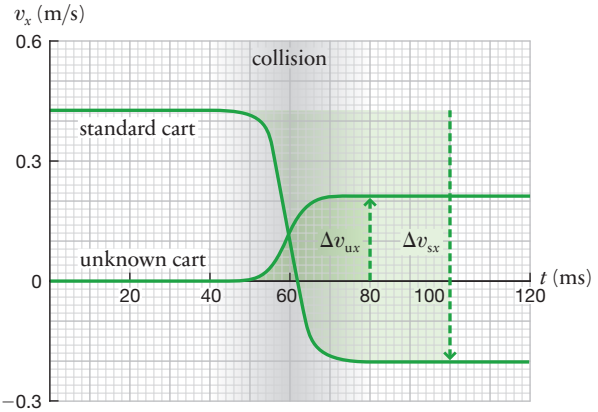
The results of our experiments are summarized in **Table 4.1**. As you can see, the *ratio of the inertias* of the two carts is equal to the inverse of the ratio of their velocity changes. In experiment 2, the double cart inertia is twice the standard cart inertia, and the ratio $|\Delta v_{dx}| : |\Delta v_{sx}|$ is 0.5. In experiment 3, the half cart inertia is half that of the standard cart, and the ratio $|\Delta v_{hx}| : |\Delta v_{sx}|$ is 2.

The data in Table 4.1 suggest that we could now take a new cart of unknown inertia, let a standard cart collide with it, and then *determine* from the changes in velocity the inertia of the new cart relative to that of the standard cart.

Table 4.1 Ratio of Velocity Changes in Collisions Between Two Carts

Experiment	Cart 1	Cart 2	$\lvert\Delta v_{1x}\rvert : \lvert\Delta v_{2x}\rvert$
1	standard	standard	1
2	double	standard	0.5
3	half	standard	2

An oil supertanker has an enormous inertia. Even at full throttle it can take as long as 10 min to bring a large ship to a halt, which explains why ships like the *Titanic* and the *Exxon Valdez* could not avoid a collision in spite of seeing the danger well ahead of time.



4.3 The x component of the final velocity of the standard cart in Figure 4.8 is positive. Can you make it negative by adjusting this cart's initial speed while still keeping the half cart initially at rest?

Figure 4.9 is a graph of the collision between some unknown cart and a standard cart—both solid and made of the same material. The magnitude of the unknown cart's change in velocity is one-third that of the standard cart (Checkpoint 4.4). We conclude from this result that the unknown cart's inertia is three times that of the standard cart. In other words, the amount of material in the unknown cart is three times that in the standard cart.

4.4 Verify that $|\Delta v_{ux}|/|\Delta v_{sx}| \approx 1/3$ for the two carts in Figure 4.9.

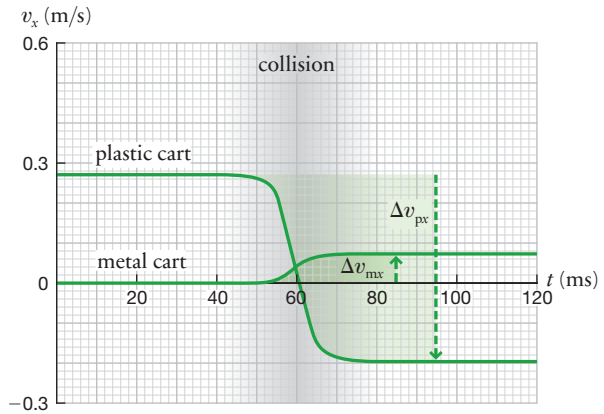
Figure 4.9 Velocity-versus-time graph for a standard cart and a cart of unknown inertia before and after the two collide on a low-friction track. The unknown inertia can be determined from the ratio of the carts' velocity changes.

CONCEPTS

4.3 What determines inertia?

Having established that an object's inertia (its resistance to a change in velocity) is proportional to the amount (roughly, volume) of material in the object, we now come to the next important question: Is it only the amount of material that determines inertia? So far, all the carts we've been studying have been made of the same material. Would our results in experiment 1 be the same if we replaced one of the standard carts with a cart of the same volume of material but made of a different material—plastic instead of metal, say? As you probably know from experience, the answer is *no:* For example, a lead ball is more difficult to set in motion than a rubber ball of equal volume.

So let's make two carts of identical amounts of material, one of plastic and the other of metal, and see what happens when the two collide. The result, shown in **Figure 4.10**, is very different from the result for two identical carts (Figure 4.5).



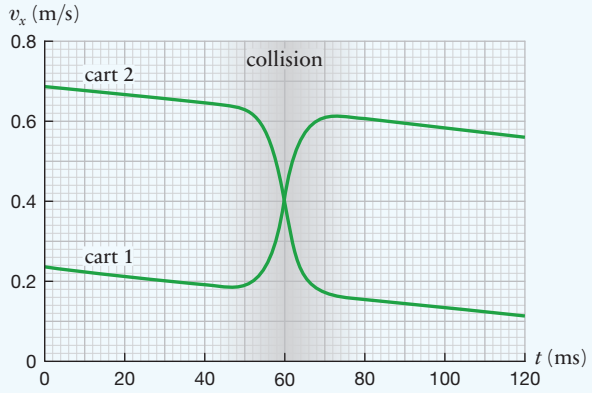
4.5 What is the ratio of the x components of the change in velocity for the plastic and metal carts, $\Delta v_{px}/\Delta v_{mx}$, in Figure 4.10?

As we expect, the x component of the velocity of the plastic cart changes by a much larger amount than that of the metal cart (but it is still opposite in sign). In other words, it is easier to change the motion of the plastic cart than the motion of the metal cart. Given that inertia is a measure of an object's tendency to resist any change in its velocity, we conclude that an object's inertia is determined not just by the volume of material it contains but also by what that material is.

What about other physical properties—shape, say, or the smoothness of an object's surface? Experiments show that inertia does not depend on any of these other properties:

The inertia of an object is determined entirely by the type of material of which the object is made and by the amount of that material contained in the object.

Figure 4.10 Velocity-versus-time graph for two colliding carts that have the same volume but are made of different materials.



Once we have chosen one object as the standard for inertia, we can determine the inertia of any other object—whatever its size, shape, or composition—by letting it collide with our standard and measuring the ratio of the changes in the velocity of the two objects.

4.6 Is the inertia of the cart of unknown inertia in Figure 4.9 greater or less than that of the standard cart?

EXAMPLE 4.1 Friction and collisions

Figure 4.11 shows the $v_x(t)$ curves for a collision between two identical carts moving not on a low-friction track but rather on a rough surface, so that friction affects their motion. Are the changes in the velocity of the carts caused by the collision still equal in magnitude?

Figure 4.11 Example 4.1.

1 GETTING STARTED Looking at the graph, I'm tempted to say yes because if I tilt Figure 4.11 a bit, it looks very similar to Figure 4.6. Determining the change in velocity due to the collision, however, is not as straightforward because friction also affects the velocities. So, because the velocities of the carts before the collision decrease due to friction, it is not possible to read off a well-defined "initial" value of the velocity. The shape of the graph suggests that friction continues to decrease the velocities in the same way during and after the collision, so I have to determine a way to separate the change in velocity due to friction from the change due to the collision.

2 DEVISE PLAN Because the effect of friction is a steady decrease in velocity, I can extrapolate the $v_x(t)$ curve for cart 1 to calculate what its velocity would have been at $t = 80$ ms if the collision had not taken place. To determine the change in velocity due to the collision, I then read off the actual value of the velocity of cart 1 at $t = 80$ ms and subtract the two velocities. Then I repeat the procedure for cart 2 and compare the changes in velocity.

3 EXECUTE PLAN By placing a ruler along the first part of the $v_x(t)$ curve for cart 1, I observe that the curve lies in line with the second part of the $v_x(t)$ curve for cart 2.

(Continued)

CONCEPTS

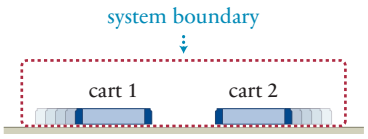
Reading off the value of the curve at $t = 80$ ms gives a value of +0.15 m/s. Repeating this procedure for cart 2, I obtain a value of +0.60 m/s. Now I can determine the velocities the carts would have had at $t = 80$ ms if the collision had not taken place. As the graph shows, however, the carts do collide and their velocities at $t = 80$ ms are interchanged. The magnitudes of the changes in velocity caused by the collision are thus 0.45 m/s and 0.45 m/s. These velocity changes are equal in magnitude. ✔

❹ **EVALUATE RESULT** Extrapolation of the velocity curves in Figure 4.11 shows that the collision interchanges the velocities of the two carts, just as in a collision between identical carts in the absence of friction. The interchanging means that the changes in velocity must be of equal magnitude, as I found numerically.

As this example shows, the magnitude of the changes in velocity in a collision is the same even in the presence of friction. This means that even in the presence of friction, we can determine an object's inertia from the magnitude of the velocity changes in a collision.

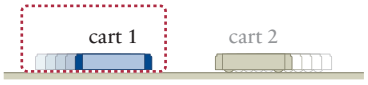
4.4 Systems

In the preceding chapters we were always concerned with just a single object—a puck, a car, and so on. Starting with this chapter, however, most situations we encounter deal with any number of objects that interact with one another. To analyze such situations, we shall usually focus on one or more principal objects—a person climbing a mountain, two carts colliding, gas atoms in a container. The first step in any analysis therefore is to separate the object(s) of interest from the rest of the universe:



Any object or group of objects that we can separate, in our minds, from the surrounding environment is a system.

For example, when considering a collision between two carts on a low-friction track, we might consider both carts together as the system. When someone throws a ball and we are interested in only the motion of the ball, a logical choice of system might be just the ball by itself. Once we have chosen the ball as our system, everything else—the thrower, the air around the ball, Earth—is outside the system and constitutes its **environment.** This imaginary separation of the universe into two parts—objects within the system and everything in the rest of the universe—makes it possible to develop simple but powerful accounting procedures.

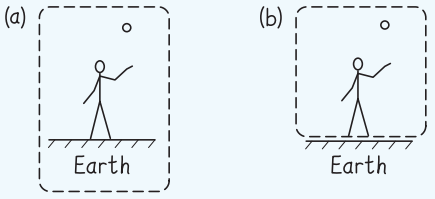


When solving problems, you should imagine a boundary enclosing the objects of interest. What is inside this well-defined boundary constitutes your system and what is outside is the environment. The region of space enclosed in the system boundary may be quite large and contain within it a great many processes or activities, or it may be very small and contain an inert piece of material undergoing no change. The precise shape of the system boundary is unimportant; what counts is that it clearly separates the objects inside the system from those outside. To make this separation explicit, it will generally be helpful to make a pictorial representation of the objects within the system. In your sketch, you should draw a boundary around the objects that constitute your system.

Figure 4.12 Two choices of system for carts colliding on a track.

(*a*) Choice 1: system consists of both carts

(*b*) Choice 2: system consists of one cart



There may be more than one way to separate the system and the environment in any given situation. For two carts colliding on a low-friction track, as illustrated in **Figure 4.12**, we can define our system as containing both carts (in which case the track is part of the environment) or just one cart (in which case the track and the other cart are part of the environment). Deciding what to include in the system will be dictated by the information you wish to learn. Often the choice is obvious; sometimes experience may help you make this decision. More important, once you decide to include a certain object in the system, *it must stay that way throughout the analysis.* Failing to make a consistent choice of system is a frequent source of error.

EXERCISE 4.2 Choosing a system

Cite at least two possible choices of system in each of the following situations. For each choice, make a sketch showing the system boundary and state which objects (excluding air) are inside the system and which are outside. (*a*) After you throw a ball upward, it accelerates downward toward Earth. (*b*) A battery is connected to a light bulb that illuminates a room.

SOLUTION (*a*) The description of the situation mentions three objects: the ball, Earth, and you. One option is to include all three of them in the system (**Figure 4.13*a***). As a second choice, I include you and the ball in the system (Figure 4.13*b*). ✔

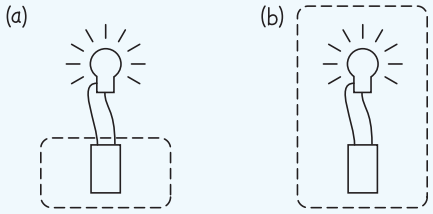


Figure 4.13

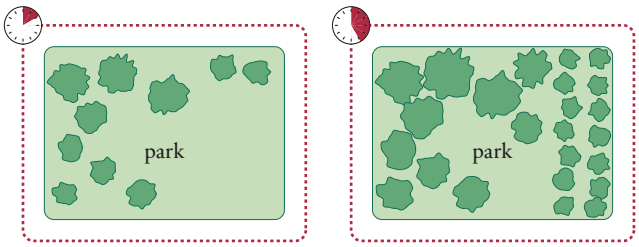
CONCEPTS

(*b*) Again I have three objects: the battery, the light bulb, and the room. I can choose just one of them—the battery—as my system (**Figure 4.14*a***) or two of them—the battery and the light bulb (Figure 4.14*b*). ✔

Figure 4.14



Note that my choices of system are arbitrary. Nothing in the problem prescribes the choice of system. If you tried this problem on your own before looking at my solution and you made different choices, then your answer is just as "correct" as mine!

Defining a system tells us nothing whatsoever about what is happening within it. It is simply a tool to help us set up an accounting scheme. Once we have chosen a system, we can study how certain quantities associated with the system change over time by determining the value of these quantities at the beginning and end of a time interval.

We shall in particular be interested in **extensive quantities**—that is, quantities whose value is proportional to the size or "extent" of the system. More specifically, if we divide the system into a number of pieces, then the sum of an extensive quantity for all the separate pieces is equal to the value of that quantity for the entire system. The number of trees in a park, for example, is extensive: If we divide the park into two parts and add the number of trees in each part, then we obtain the number of trees in the park. The price per gallon of gasoline is not an extensive quantity: If we divide a tankful of gas into two parts and add the price per gallon for the two parts, then we obtain twice the price per gallon for the entire tank. Quantities that do not depend on the extent of the system are **intensive quantities.**

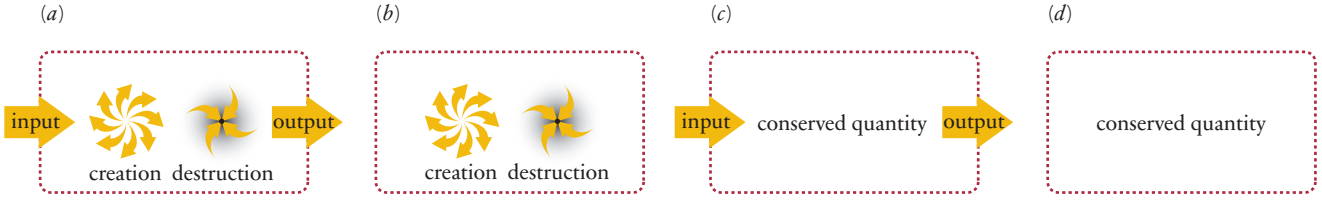
Figure 4.15 System diagram of a park. The number of trees in the park is an extensive quantity.

4.7 Are the following quantities extensive or intensive: (*a*) inertia, (*b*) velocity, (*c*) the product of inertia and velocity?

Only four processes can change the value of an extensive quantity: input, output, creation, and destruction. To see this, consider **Figure 4.15**, which schematically represents a park's initial and final conditions over a certain time interval. The edge of the park is the system boundary, and the park itself—trees and all—is the system. Diagrams that show a system's initial and final conditions are called **system diagrams;** we shall use such diagrams throughout this book. The change in the number of trees over the time interval is given by

$$\text{change} = \text{final tree count} - \text{initial tree count}.$$

The number of trees can change because new trees grow (creation) and old trees die or are taken down (destruction). Alternatively, new trees can be brought into the park (input) and some trees can be moved out of the park (output):



$$\text{change} = \text{input} - \text{output} + \text{creation} - \text{destruction}.$$

This equation is illustrated graphically in **Figure 4.16*a***. If we understand how these four processes affect the trees, we can explain (or predict) any change in their number.

The accounting is often simplified by constraints put on the system. For example, if we build a fence around the park so that no trees can be transported into or out of the park, then the number of trees can change only

CONCEPTS

Figure 4.16 The effect of input, output, creation, and destruction on the extensive quantities of a system.

Extensive quantities can be changed by input, output, creation, and destruction.

If there is no input or output, the quantity can be changed only by creation or destruction.

If an extensive quantity cannot be created or destroyed, it is said to be conserved.

If there is no input or output, a conserved quantity cannot change.

because of creation and destruction. If there is no transfer of the extensive quantity under consideration across the boundary of the system, the change in that property can be due to only creation and destruction (Figure 4.16*b*):

$$\text{change} = \text{creation} - \text{destruction}.$$

Under certain circumstances we can also exclude creation and destruction. Suppose, for example, that we are counting the number of indestructible benches in the park rather than trees. The number of these benches changes only when benches are transported into or out of the park across the park boundary (unless there is a factory making indestructible benches in the park—an unlikely assumption). Any extensive quantity that cannot be created or destroyed is said to be **conserved.** The value of a conserved quantity can change only due to transfer of that quantity across the system boundary (Figure 4.16*c*):

$$\text{change} = \text{input} - \text{output}.$$

For a conserved quantity in a system for which there is no transfer, things are even more simple: Its value cannot change at all (Figure 4.16*d*). Conserved quantities play an important role in physics because their accounting is greatly simplified. In systems for which there is no transfer of a conserved quantity across the system boundary, this quantity does not change *regardless of the processes occurring inside or outside the system* (see the box "Conservation").

EXERCISE 4.3 Accounting principles

(*a*) Classify and give examples of the kinds of processes that can change (*i*) the number of loaves of bread in a bakery, (*ii*) the number of Lego pieces inside a house, and (*iii*) the number of coins in a safe that remains locked. (*b*) For each of these three cases, what is the system? Is the transfer of the quantity of interest across the system boundary possible? Is the quantity of interest conserved?

SOLUTION (*a*) (*i*) Input: a delivery of loaves of bread to the bakery; output: customers leaving the bakery with loaves they purchased; creation: the baking of a batch of loaves; destruction: the eating of loaves by patrons (inside the bakery; destruction outside the bakery falls under "output" because the loaves first leave the bakery). (*ii*) Input: Lego pieces are brought into the house; output: Lego pieces are taken out of the house; creation: assuming there is no manufacturing of Lego pieces in the house, there is no creation; destruction: for all practical purposes, I can consider the Lego pieces to be indestructible and so there is no destruction. (*iii*) Input: if the safe is locked it's impossible to add coins, so the input is zero; output: zero, too; creation: zero; destruction: zero. (Everything is zero, meaning the number of coins can't change inside a locked safe—which is precisely why people put valuables in safes!) ✔

Conservation

Imagine a sheet of paper of width a and length b. The circumference of this sheet is $2a + 2b$, and the surface area of one side is ab. Suppose we cut the sheet lengthwise into two equal parts. Are there any quantities that are unchanged by the cutting?

Circumference is not a conserved quantity: The sum of the circumferences of the two parts is not equal to the circumference of the single sheet. The circumference of each cut piece is $2\left(\frac{1}{2}a\right) + 2b$, and the combined circumference of the two pieces is $2(a + 2b)$, whereas the original circumference was $2(a + b)$.

Surface area is conserved: The surface area of each cut piece is $\frac{1}{2}ab$, and so the sum of the surface areas of the two pieces is ab, exactly as it was before we cut up the sheet.

Trivial? Well, suppose that instead of cutting the sheet in two, we cut it into 148 equal pieces. Can we say anything about the sum of the circumferences? Not without some brainwork! Conservation of surface area, on the other hand, allows us to state—with no calculations whatsoever—that the sum of the surface areas of all the pieces is still ab.

We have found a conserved quantity: surface area! No matter in how many pieces a sheet of paper is cut, the sum of the surface areas of the pieces is equal to the surface area of the original sheet.

If you are a skeptic (and in science you should always be skeptical), you could calculate the surface area of one of the 148 pieces and verify that the sum of the surface areas of all the pieces is indeed ab. To convince yourself that conservation of surface area is a general law, you might also want to repeat this procedure for a few more cases—say, 79 and 237 pieces.

Once you are convinced, however, it is easy to see the value of the conservation law. Suppose that instead of cutting the sheet neatly into equal pieces, someone tears it into ragged pieces, hands them to you, and asks, "What is the combined surface area of all of these pieces?" Even though an actual determination of the surface area would be difficult at best, you would answer, without hesitation, "ab"!

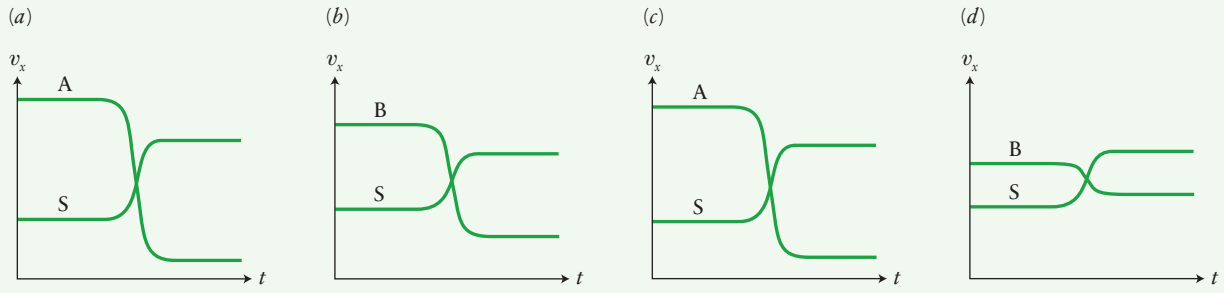
The idea that certain quantities are unaffected by events is appealing, not only because the notion of conservation intuitively makes sense (*some* things must remain unchanged) but also because it provides simple constraints on the behavior of a system.

Is surface area truly conserved? The answer is *no:* you can burn the sheet and make the entire surface area disappear. As we shall see, only a few quantities are truly conserved.

CONCEPTS

(*b*) (*i*) The bakery and its contents make up the system. Loaves of bread can be taken into and out of the bakery, so transfer is possible. The number of loaves of bread is not conserved because loaves can be created and destroyed. (*ii*) The house and its contents are the system. Lego pieces can be taken into and out of it, so transfer is possible. Assuming that the Lego pieces cannot be fabricated or destroyed, I can consider their number to be conserved in this problem. (*iii*) The safe and its contents are the system. The safe remains locked so nothing can be put into it or taken out, and so transfer is not possible. Coins cannot be made or destroyed, so their number is conserved. ✔

Strictly speaking, indestructible benches in a park, Lego pieces, and coins are not truly conserved—all of them are manufactured somewhere (creation) and all of them can be destroyed (destruction). You may be wondering, then, whether *anything* is conserved. The answer is yes: Several quantities we shall encounter are conserved, giving rise to some of the most fundamental principles in physics.



4.8 Which of these quantities is extensive? (*a*) money, (*b*) temperature, (*c*) humidity, (*d*) volume.

Self-quiz

1. Two carts give the same velocity-versus-time graphs when they collide with the same standard cart. Can you conclude from this information that the two carts are identical?
2. The graphs in **Figures 4.17*a*** and 4.17*b* show the effects of carts A and B colliding (separately) with a standard cart S. List the three carts in order of increasing inertia.

Figure 4.17

3. The graphs in Figures 4.17*c* and 4.17*d* show the effects of carts A and B colliding (separately) with a standard cart S. Which has greater inertia, A or B?
4. You do not know whether or not carts A and B of question 3 are made of the same material. Can you tell from the graphs which cart contains a larger quantity of material?
5. Imagine accounting for the number of cattle on a ranch. What do you choose as your system? What are the processes corresponding to input, output, creation, and destruction? Is transfer into and out of the system possible? Is the accountable quantity conserved?

Answers

1. No. Although the identical graphs tell you that the two carts have identical inertias, they need not be identical physically. A large plastic cart, for instance, can have the same inertia as a much smaller metal cart.
2. A and B (identical and less), S (greater). Because the magnitude of the velocity change for S is smaller than that for either A or B, cart S must have greater inertia. The *ratio* of the magnitudes of the velocity changes is about the same in both graphs, however, indicating that A and B have about the same inertias.
3. B. Don't be fooled by the bigger velocity change for S in part *c*; you must first consider each graph separately. Graph *c* tells you that A has less inertia than S because the magnitude of the velocity change for A is *larger* than that for S. Graph *d* tells you that B has greater inertia than S because the magnitude of the velocity change for B is *smaller* than that for S. Hence B must have greater inertia than A.
4. No. Although B has greater inertia, you cannot conclude anything about the quantity of material in it relative to A because you don't know from what materials the two carts are made.
5. The ranch is the system. Input: cattle transported into the ranch; output: cattle transported out of the ranch; creation: cattle born on the ranch; destruction: cattle expiring on the ranch. Transfer is possible because there is input and output, and the number of cattle is not conserved because cattle can be created and destroyed.

4.5 Inertial standard

The inertia of an object is represented by the symbol m (m is for *mass*, a concept that is related to inertia and that we shall examine later on). We shall use the term *inertia* rather than *mass* to underscore the physical meaning of this concept: An object's resistance to a change in its velocity. Inertia is a scalar, which means it does not depend on the orientation of any axis in space. By international agreement, the inertial standard used to be a platinum-iridium cylinder stored at the International Bureau of Weights and Measures in Sèvres, France. The inertia of this standard was defined as one **kilogram,** the basic SI unit of inertia ($m_s \equiv 1\ \text{kg}$).* As of 2019, the kilogram is defined in terms of fundamental constants; to within a precision of 0.003%, it is equal to the inertia of 1 liter of pure water at 4° C.

We can consider an inertial standard to be any "reference" block of metal that is known to have an inertia of 1 kg. Armed with the knowledge gained in Sections 4.1 through 4.3, we can determine the inertia m of any other object. To do so, we make the object we are studying collide with the inertial standard and then measure the changes in velocity. In Section 4.2, we defined the ratio of the inertias of two colliding objects as the inverse of the ratio of the magnitude of their velocity changes, and so we can use this ratio for our inertial standard and our object of unknown inertia:

$$\frac{m_u}{m_s} \equiv -\frac{\Delta v_{sx}}{\Delta v_{ux}} \tag{4.1}$$

or

$$m_u \equiv -\frac{\Delta v_{sx}}{\Delta v_{ux}} m_s. \tag{4.2}$$

Why the minus sign? Well, suppose the object of unknown inertia is a replica of the standard. The left side of Eq. 4.1 then becomes $m_s/m_s = 1$. From the collision in Figure 4.5, we know, however, that the velocity of one of the carts increases (positive Δv_x) while that of the other decreases by the same amount (negative Δv_x). Without the minus sign, Eq. 4.1 would therefore become $1 = -1$. Notice that in all collisions we considered (Figures 4.5 through 4.9), the x components of the velocity change for the two colliding objects have opposite signs. Because this is true for *all* collisions, the minus sign in Eq. 4.1, the defining equation for inertia, means inertia is always a *positive* quantity.

In principle, this simple procedure makes it possible to determine the inertia of any object. Substituting the value $m_s \equiv 1$ kg in Eq. 4.2 allows us to determine the inertia of any other object in kilograms. In practice, it may not be a good idea to let objects collide in order to determine their inertia. (I don't recommend determining the inertia of an expensive glass vase in this way!) In Chapter 13 we shall discuss equivalent but more practical ways to determine the inertia of objects.

EXAMPLE 4.4 Determining the inertia of a stone

A small stone is fastened to the top of a standard cart of inertia 1 kg to form a combination of unknown inertia m_u. A second standard cart is then launched with an initial velocity given by $v_{sx,i} = +0.46$ m/s toward the combination that is initially at rest. After the collision, the x component of the velocity of the cart with the stone is $v_{ux,f} = +0.38$ m/s and that of the standard cart is $v_{sx,f} = -0.08$ m/s. What is the inertia of the stone?

❶ **GETTING STARTED** This collision is much like the one depicted in Figure 4.7 with a standard cart moving toward a cart of greater inertia that is initially at rest. The ratio of the carts' inertias follows from the ratio of the magnitude of their velocity changes.

(Continued)

*You should not associate the unit kilogram with *weight*, a physical property that has to do with gravitation rather than inertia. More about the concept of weight in Chapter 13.

2 DEVISE PLAN To calculate the unknown inertia m_u, I can use Eq. 4.2. I know the x components of the two carts' initial and final velocities, so all the quantities on the right side of the equation are known.

3 EXECUTE PLAN I begin by determining the changes in the x components of the velocity for each cart. For the cart with the stone, $\Delta v_{ux} = v_{ux,f} - v_{ux,i} = +0.38\ \text{m/s} - 0 = +0.38\ \text{m/s}$; for the standard cart $\Delta v_{sx} = v_{sx,f} - v_{sx,i} = -0.08\ \text{m/s} - 0.46\ \text{m/s} = -0.54\ \text{m/s}$. Substituting these values into Eq. 4.2, I get

$$m_u = -\frac{\Delta v_{sx}}{\Delta v_{ux}} m_s = -\frac{-0.54\ \text{m/s}}{+0.38\ \text{m/s}}(1\ \text{kg}) = 1.4\ \text{kg}.$$

This represents the inertia of the stone and the cart as one unit. Given that the inertia of the standard cart is 1 kg, the inertia of the stone must be 0.4 kg. ✔

4 EVALUATE RESULT The inertia of the cart-and-stone combination is greater than 1 kg, as I would expect. If the magnitude of the velocity change of this combination were half that of the standard cart $\left(\frac{1}{2}(0.54\ \text{m/s}) = 0.27\ \text{m/s}\right)$, then the inertia of the cart-and-stone combination would be twice that of a standard cart, and so the inertia of the stone would be 1.0 kg. The magnitude of the velocity change is more than half, so I should expect the stone's inertia to be less than 1.0 kg, which agrees with the answer I found.

4.6 Momentum

Our definition of inertia leads to the definition of another important physical quantity: *momentum*. Let's rewrite Eq. 4.2 in a slightly different form by multiplying both sides by Δv_{ux} and then bringing all terms to the left side:

$$m_u \Delta v_{ux} + m_s \Delta v_{sx} = 0. \tag{4.3}$$

Because the changes in velocity Δv_x can be written in the form $v_{x,f} - v_{x,i}$, we can rewrite this equation as

$$m_u(v_{ux,f} - v_{ux,i}) + m_s(v_{sx,f} - v_{sx,i}) = 0 \tag{4.4}$$

or

$$m_u v_{ux,f} - m_u v_{ux,i} + m_s v_{sx,f} - m_s v_{sx,i} = 0. \tag{4.5}$$

This form of Eq. 4.3, which contains nothing but products of inertias and velocities, is important because it suggests something new. The product of the inertia and the velocity of an object is called the **momentum** (plural: *momenta*) of that object. The conventional symbol for momentum is p, and so we can write

$$\vec{p} \equiv m\vec{v}. \tag{4.6}$$

As you learned in Section 2.6, the product of a vector and a scalar is a vector. Because inertia is a scalar and velocity is a vector, momentum is a vector. The direction of the momentum vector for any object is the same as the direction of the object's velocity vector. The x component of the momentum is the product of the inertia and the x component of the velocity:

$$p_x \equiv mv_x. \tag{4.7}$$

The SI units of momentum are the units of the product mv: $\text{kg} \cdot \text{m/s}$. For example, the magnitude of the momentum of an object of inertia 1 kg moving at a speed of 1 m/s is $1\ \text{kg} \cdot \text{m/s}$. Inertia is an intrinsic property of an object (you can't change it without changing the object), but the value of the momentum of that object, like its velocity, can change.

QUANTITATIVE TOOLS

EXAMPLE 4.5 Bullet and bowling ball

Compare the magnitude of the momenta of a 0.010-kg bullet fired from a rifle at 1300 m/s and a 6.5-kg bowling ball lumbering across the floor at 4.0 m/s.

❶ **GETTING STARTED** Momentum is the product of inertia and velocity. I have to calculate this quantity for both the bullet and the bowling ball and then compare the resulting values.

❷ **DEVISE PLAN** Equation 4.6 gives the momentum of an object. To determine the magnitude of the momentum of an object, I must take the product of the inertia m and the speed v: $p = mv$.

❸ **EXECUTE PLAN** Substituting the values given in the problem statement, I get

$$p_{\text{bullet}} = (0.010\ \text{kg})(1300\ \text{m/s}) = 13\ \text{kg}\cdot\text{m/s} \checkmark$$
$$p_{\text{bowling}} = (6.5\ \text{kg})(4.0\ \text{m/s}) = 26\ \text{kg}\cdot\text{m/s}. \checkmark$$

❹ **EVALUATE RESULT** Surprisingly, the magnitudes of the momenta are very close! I have no way of evaluating momenta because I don't have much experience yet with this quantity. However, the bullet has less inertia and a high speed and the bowling ball has greater inertia and a low speed, so it is not unreasonable that the product of these quantities is similar.

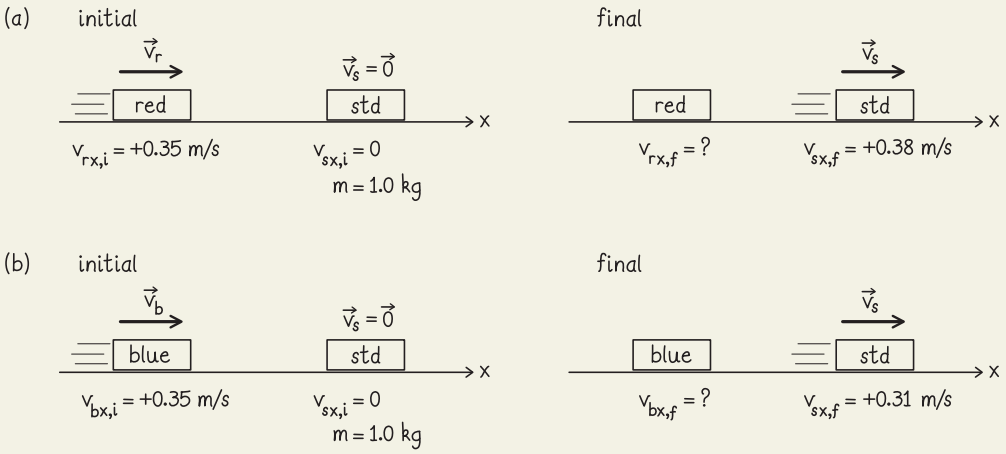
Momentum is a quantitative measure of "matter in motion" and depends on both the amount of matter in motion and how fast that matter is moving. Momentum is very different from inertia. A truck, for example, has greater inertia than a fly (it has a higher resistance to a change in its velocity), but if the truck is at rest and the fly is in motion, then the magnitude of the fly's momentum is larger than that of the truck, which is zero. In Example 4.5, the inertias of the bullet and the bowling ball are very different, yet their momenta are similar. Conceptually you can think of an object's momentum as its capacity to affect the motion of other objects in a collision.

With the definition of momentum, we can rewrite Eq. 4.5 in the form

$$p_{ux,f} - p_{ux,i} + p_{sx,f} - p_{sx,i} = 0. \tag{4.8}$$

If we write $\Delta p_{ux} \equiv p_{ux,f} - p_{ux,i}$ and $\Delta p_{sx} \equiv p_{sx,f} - p_{sx,i}$, Eq. 4.8 takes on the beautifully simple form

$$\Delta p_{ux} + \Delta p_{sx} = 0. \tag{4.9}$$



This equation means that, whenever an object of unknown inertia collides with the inertial standard, the changes in the x components of the momenta of the two objects add up to zero. In other words, the change in the x component of the momentum for one object is always the negative of the change for the other.

EXAMPLE 4.6 Collisions and momentum changes

(*a*) A red cart with an initial speed of 0.35 m/s collides with a stationary standard cart ($m_s = 1.0$ kg). After the collision, the standard cart moves away at a speed of 0.38 m/s. What is the momentum change for each cart? (*b*) The experiment is repeated with a blue cart, and now the final speed of the standard cart is 0.31 m/s. What is the momentum change for each cart in this second collision? (*c*) If in the collisions $v_{rx,f} = +0.032$ m/s and $v_{bx,f} = -0.039$ m/s, what are the inertias of the red and the blue carts?

❶ **GETTING STARTED** I begin organizing the information given in the problem in a picture by showing the initial and final conditions for each of the two collisions (**Figure 4.18**).

Figure 4.18

(Continued)

2 DEVISE PLAN In each collision, I know the inertia and the x components of the initial and final velocities of the standard cart, so I can readily determine the change in the x component of its momentum. To determine the change in momentum for the other carts, I can then use Eq. 4.9, which tells me that for each collision the changes in the x components of the momenta of the two carts must add up to zero. For part c, I can use Eq. 4.7 together with the values for the red and blue carts' initial and final velocities and their changes in momenta calculated in parts a and b to determine the inertias.

3 EXECUTE PLAN (a) Because it initially is at rest, the standard cart's initial momentum is zero. The x component of its final momentum is $p_{sx,f} = (1.0\ \text{kg})(+0.38\ \text{m/s}) = +0.38\ \text{kg}\cdot\text{m/s}$, and so the x component of its change in momentum is

$$\Delta p_{sx} = +0.38\ \text{kg}\cdot\text{m/s} - 0 = +0.38\ \text{kg}\cdot\text{m/s}. \checkmark$$

Because the x components of the momentum changes of the two carts must add up to zero (Eq. 4.9), the corresponding x component of the red cart's momentum change is $\Delta p_{rx} = -0.38\ \text{kg}\cdot\text{m/s}$. ✔

(b) Applying the same procedure for this second collision, I get

$$\Delta p_{sx} = (1.0\ \text{kg})(+0.31\ \text{m/s}) - 0 = +0.31\ \text{kg}\cdot\text{m/s};$$

$$\Delta p_{bx} = -0.31\ \text{kg}\cdot\text{m/s}. \checkmark$$

(c) The change in momentum for the red cart is $\Delta p_{rx} = p_{rx,f} - p_{rx,i}$. Using Eq. 4.7, I can write this change in momentum as

$$\Delta p_{rx} = m_r v_{rx,f} - m_r v_{rx,i} = m_r(v_{rx,f} - v_{rx,i})$$

and so

$$m_r = \frac{\Delta p_{rx}}{v_{rx,f} - v_{rx,i}} = \frac{-0.38\ \text{kg}\cdot\text{m/s}}{+0.032\ \text{m/s} - 0.35\ \text{m/s}}$$
$$= 1.2\ \text{kg}. \checkmark$$

Likewise, for the blue cart:

$$m_b = \frac{\Delta p_{bx}}{v_{bx,f} - v_{bx,i}} = \frac{-0.31\ \text{kg}\cdot\text{m/s}}{-0.039\ \text{m/s} - 0.35\ \text{m/s}}$$
$$= 0.80\ \text{kg} \checkmark$$

4 EVALUATE RESULT If either the red or the blue cart had an inertia of 1.0 kg, then the cart would come to rest in the collision. My work shows that the inertia of the red cart is greater than that of a standard cart. Indeed, after the collision it still moves in the same direction it initially moved, as it should for a cart of greater inertia colliding with one of lesser inertia (see, for example, Figure 4.8). In contrast, the inertia of the blue cart is less than that of the standard cart. After the collision it bounces back and travels in the opposite direction, as I would expect (see Figure 4.7).

Equation 4.9 can be written in vectorial form:

$$\Delta\vec{p}_u + \Delta\vec{p}_s = \vec{0} \tag{4.10}$$

and so, in a collision between an object of unknown inertia and the inertial standard, the changes in the momenta of the two objects add to zero.

4.9 In part a of Example 4.6, what are the directions of the changes in momentum, $\Delta\vec{p}_s$ and $\Delta\vec{p}_r$, of the two carts?

4.7 Isolated systems

As we saw in Checkpoint 4.7, momentum is an extensive property—you can add up the momenta of all the objects in a system to obtain the *momentum of the system*. In particular, the momentum of a system of two moving carts is the sum of the momenta of the two individual carts:

$$\vec{p} \equiv \vec{p}_1 + \vec{p}_2. \tag{4.11}$$

With this definition we can begin to develop an accounting scheme for the momentum of a system. In particular, we shall be interested in determining what causes the momentum of a system to change. Let us begin by reexamining a number of situations we have encountered. In Figure 4.19*a* a puck slides to a stop on a wood floor. In Figure 4.19*b* a cart moves at constant velocity on a low-friction track. In Figure 4.19*c* a standard cart collides with another cart on a low-friction track, and in Figure 4.19*d* someone gives a cart moving at constant velocity on a low-friction track a shove. In some cases the velocity (and therefore the momentum) remains constant; in others it changes.

Figure 4.19 Velocity-versus-time and acceleration-versus-time graphs for four situations. The shading indicates nonzero acceleration.

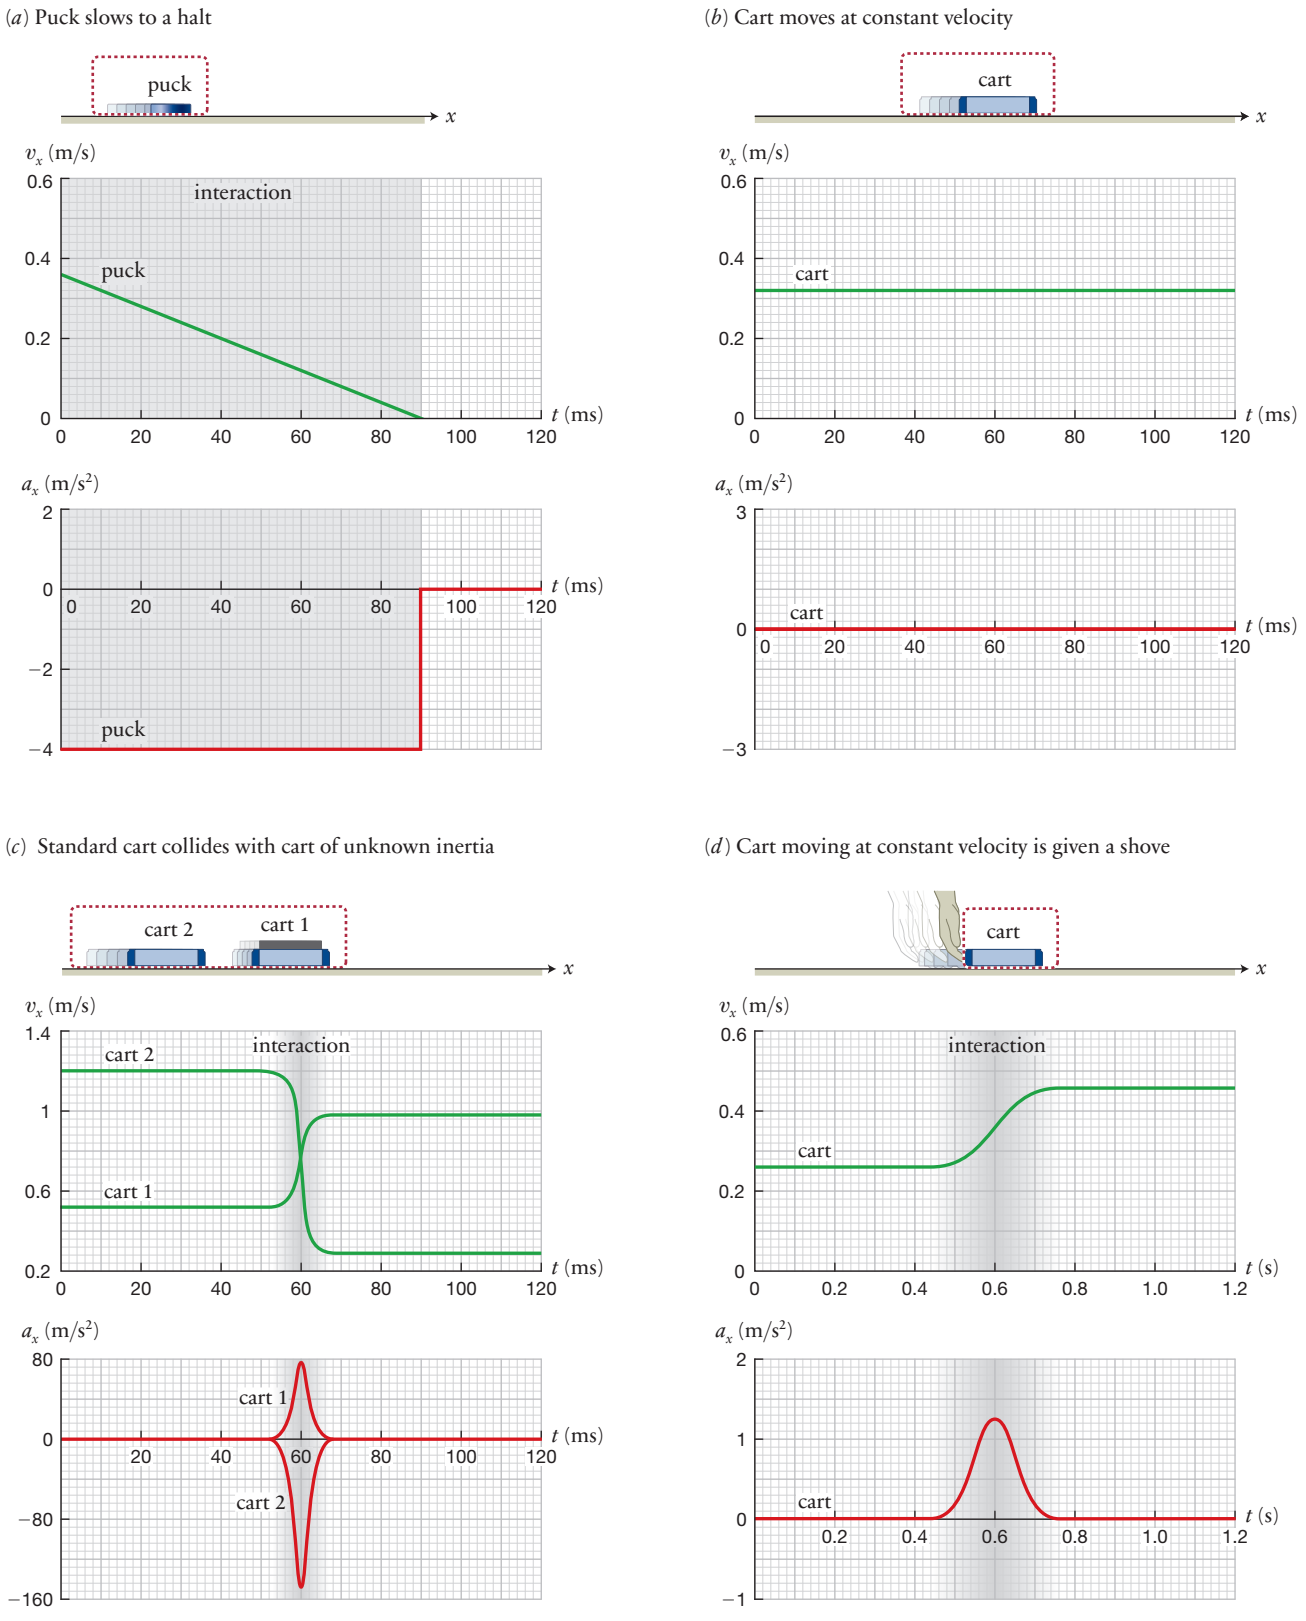


Table 4.2 Interactions and momentum changes in Checkpoint 4.10

Situation	Interacting objects	System	System interacting?	$\Delta\vec{p}$
a	floor ↔ puck	puck	yes	nonzero
b	none	cart	no	$\vec{0}$
c	cart 1 ↔ cart 2	cart 1	yes	nonzero
d	cart 1 ↔ cart 2	carts 1 & 2	no	$\vec{0}$
e	hand ↔ cart	cart	yes	nonzero

4.10 Is the change in the momentum $\Delta\vec{p}$ zero or nonzero for the following choices of system over the 120-ms time interval in Figure 4.19: (*a*) puck in Figure 4.19*a*, (*b*) cart in Figure 4.19*b*, (*c*) cart 1 in Figure 4.19*c*, (*d*) both carts in Figure 4.19*c*, (*e*) cart in Figure 4.19*d*?

In the graphs, I have highlighted the time intervals during which the acceleration of objects within the system is nonzero—that is, the time interval when the velocity and therefore the momentum of objects within the system change. Notice that this time interval always coincides with the time interval during which the object under consideration *interacts* with something else. In Figure 4.19*a* the puck slows down because the puck and the floor rub against (interact with) each other, in Figure 4.19*c* the two carts collide with (interact with) each other, and in Figure 4.19*d* the cart and the hand interact with each other. Conversely, in Figure 4.19*b* the interaction between the track and the cart has been virtually eliminated by reducing friction, and so the acceleration is zero.

In these examples, *interaction* refers to objects touching or rubbing against each other. Interactions are the subject in Chapter 7. For now, we'll use the word *interaction* to mean two objects acting on each other in such a way that one or both are accelerated.

Table 4.2 summarizes the observations from Checkpoint 4.10. Note that whenever the system interacts with something outside the system, the momentum of the system changes. Interactions across the boundary of a system are called *external interactions*. Interactions between two objects inside the system are called *internal interactions*. Looking at Figure 4.19 and Table 4.2, we see that external interactions transfer momentum into or out of the system.

A system for which there are no external interactions is said to be **isolated.** For such a system there is no input or output of momentum, and so the momentum of the system does not change: $\Delta\vec{p} = \vec{0}$. In Figure 4.19*b*, the cart's motion is not influenced by the track, and so the cart constitutes an isolated system. In Figure 4.19*c*, the two carts interact with each other but not with anything outside the system, and so the two carts together constitute a system that is isolated (but either cart by itself does not; see Table 4.3). In Figures 4.19*a* and 4.19*d*, where $\Delta\vec{p} \neq \vec{0}$, the system is not

Table 4.3 Two choices of system for carts colliding

	Choice 1	Choice 2
System:	carts 1 & 2	cart 1
Environment:	track	cart 2 & track
Interactions:	internal	external
System isolated?	yes	no
Momentum changing?	no	yes

QUANTITATIVE TOOLS

isolated. In Figure 4.19*a* the only object in the system (the puck) interacts with the floor, which is outside the system. In Figure 4.19*d*, the only object in the system (the cart) interacts with the hand, which is outside the system.

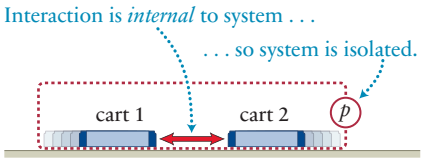

Figure 4.20 and Table 4.3 illustrate two system choices for studying a collision. The system containing both carts is isolated (the interaction between the two carts takes place inside the system; it is an internal interaction), and the momentum of the system is constant. The system containing just cart 1 is not isolated because it interacts with cart 2, which is now part of the environment, and the momentum of the system is not constant.

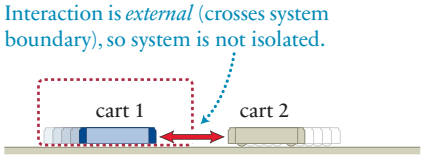
In isolated systems the analysis of momentum is simplified because we can concentrate on what happens inside the system. The procedure for choosing an isolated system is shown in the Procedure box on the next page and illustrated for a collision between two carts on a low-friction track in **Figure 4.21**. We begin by separating from one another all the objects that could play a role: the carts, the track, and the air. Next we identify all possible interactions: the collision between the two carts, the interaction between the air and the carts, and any possible interaction between the track and the carts. We know that each cart by itself rolls without slowing down on the track, so the interaction between the track and the carts and between the air and the carts does not have any significant effect on the carts' velocity. We therefore eliminate these and retain only the collision between the carts, which does change their velocities.*

Having eliminated all but the interaction between the carts, we can choose an isolated system by enclosing the two carts so that this interaction becomes internal. Finally, we complete the procedure by making a system diagram, showing the initial and final conditions of the isolated system (before and after the collision). In general, the interaction between two colliding objects affects their motion much more strongly than any other interaction, and so we can for all practical purposes always consider the system of two colliding objects to be isolated.

Figure 4.20 The choice of system determines whether the interactions in question are internal or external and hence whether the system is isolated or not. We use the symbol Ⓟ to denote an isolated system, indicating that no momentum crosses the system's boundary.

(*a*) Choice 1: system = both carts

(*b*) Choice 2: system = cart 1



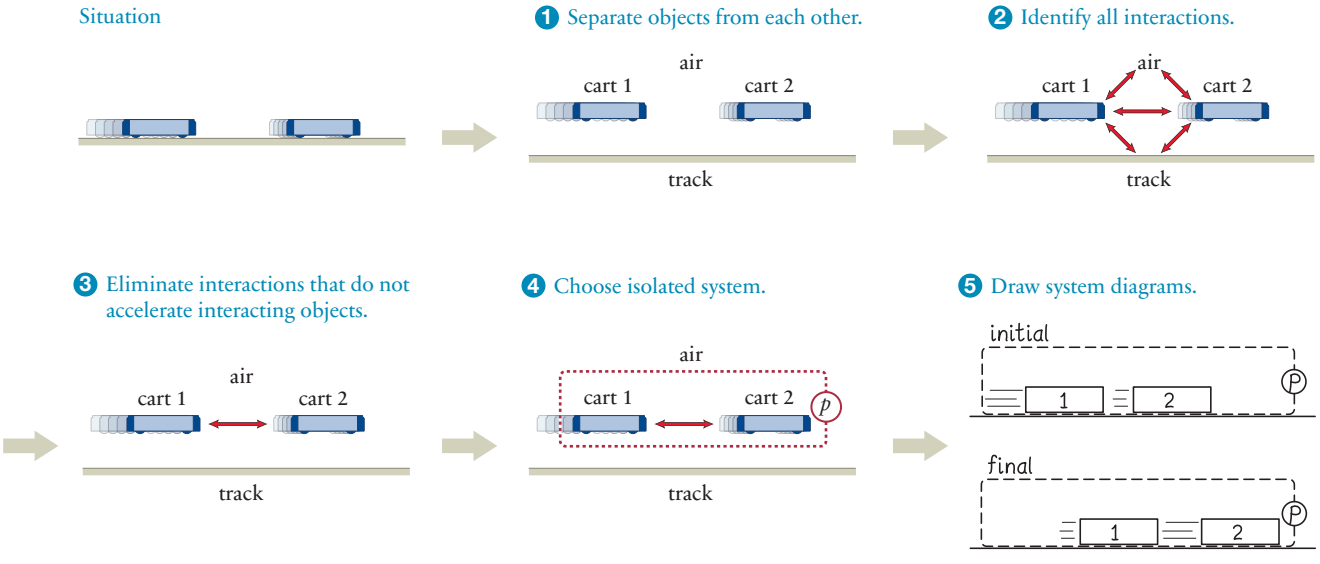


Figure 4.21 Applying the procedure for choosing an isolated system (see the Procedure box) to the collision between two carts on a low-friction track.

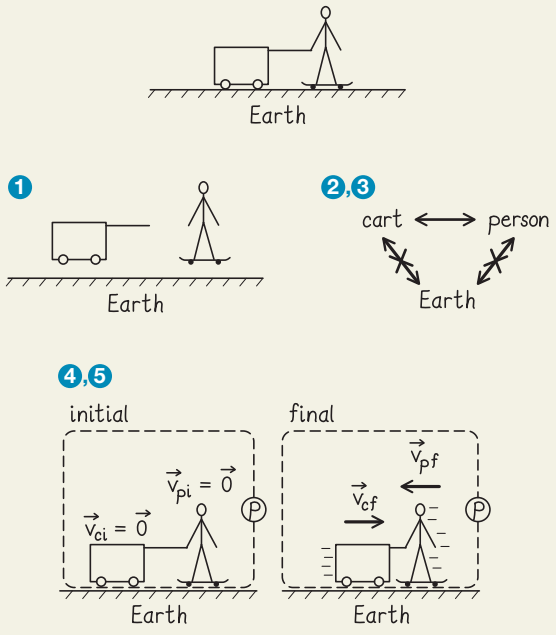
*Leaving out the air-cart and track-cart interactions is a simplification, because both *do* have a small effect on the carts' acceleration. However, you can ignore the effects of the these interactions because they are so much smaller than the effects of the collision. Never be afraid to make a simplifying assumption; you can always return to the beginning of a problem and refine your assumptions.

PROCEDURE: Choosing an isolated system

When you analyze momentum changes in a problem, it is convenient to choose a system for which no momentum is transferred into or out of the system (an isolated system). To do so, follow these steps:



1. Separate all objects named in the problem from one another.
2. Identify all possible interactions among these objects and between these objects and their environment (the air, Earth, etc.).
3. Consider each interaction individually and determine whether it causes the interacting objects to accelerate. Eliminate any interaction that does not affect (or has only a negligible effect on) the objects' accelerations during the time interval of interest.
4. Choose a system that includes the object or objects that are the subject of the problem (for example, a cart whose momentum you are interested in) in such a way that none of the remaining interactions cross the system boundary. Draw a dashed line around the objects in your choice of system to represent the system boundary. None of the remaining interactions should cross this line.
5. Make a system diagram showing the initial and final states of the system and its environment.

EXERCISE 4.7 Who's pulling whom?

A person standing on a skateboard on horizontal ground pulls on a rope fastened to a cart. Both the person and the cart are initially at rest. Use the Procedure box to identify an isolated system and make a system diagram.

SOLUTION See **Figure 4.22**. I begin by separating the objects in the problem: the person, the cart, and Earth. (I could always go into more detail—include the air, the rope, and the skateboard—but it pays to keep things as simple as possible. For that reason, I consider the skateboard to be part of the person and the rope to be part of the cart.) The cart interacts with Earth and the person; the person interacts with the cart and Earth. Ignoring friction in the wheels of the cart, I know that the interaction between the cart and Earth has no effect on any motion, and so I can eliminate it from the analysis. The same holds for the interaction between the person (the skateboard) and Earth. I then draw a boundary around the person and the cart, making the interaction between the two internal. Because there are no external interactions, this system is isolated. Finally I draw a system diagram showing the initial and final conditions of the system with the person and cart initially at rest and then moving. ✔

Figure 4.22

4.11 Imagine sitting on a sled on the slippery surface of a frozen lake. To reposition yourself closer to the back of the sled, you push with your legs against the front end. (*a*) Do you constitute an isolated system? (*b*) How about you and the sled? Ignore the interaction between sled and ice.

4.8 Conservation of momentum

In Section 4.4 we saw that the change in an extensive property can be due to transport into or out of the system and to creation or destruction. In Section 4.7 we saw that whenever we consider a system that is isolated, the momentum of the system is not changing:

$$\Delta\vec{p} = \vec{0} \quad (\text{isolated system}). \tag{4.12}$$

You may be tempted to conclude from this observation that momentum is conserved. All we can conclude, however, is that there is no creation or destruction of momentum *inside the systems we considered*—not that it is impossible to create or destroy momentum under any circumstances.

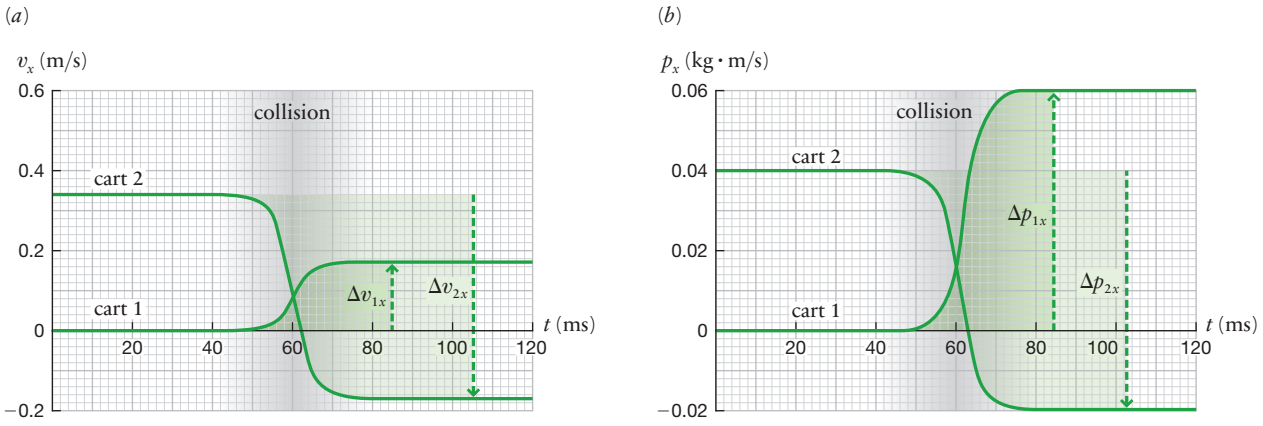
Because it is a direct consequence of the definition of momentum, Eq. 4.10 must—by definition—hold for *any* object that collides with the inertial standard. So if we take any two objects 1 and 2 and let each collide with the inertial standard on a level, low-friction track, we *always* obtain—no matter how we vary the initial velocities and no matter what the values of inertias m_1 and m_2 are—that

$$\Delta\vec{p}_1 + \Delta\vec{p}_s = \vec{0} \quad (\text{by definition}) \tag{4.13}$$

and

$$\Delta\vec{p}_2 + \Delta\vec{p}_s = \vec{0} \quad (\text{by definition}). \tag{4.14}$$

Suppose now that, instead of making objects 1 and 2 collide with the inertial standard, we make them collide with each other. Should we expect to obtain



$$\Delta\vec{p}_1 + \Delta\vec{p}_2 = \vec{0}? \tag{4.15}$$

You may be tempted to think that this equation follows from our earlier observations, but that is not the case. The value of $\Delta\vec{p}_s$ in Eqs. 4.13 and 4.14 need not be the same because Δv_{sx}, and therefore $\Delta\vec{p}_s$, vary from collision to collision (compare, for instance, Figures 4.8 and 4.9). So each of these equations holds for a separate collision and therefore we cannot combine them to draw any conclusions about the relationship between $\Delta\vec{p}_1$ and $\Delta\vec{p}_2$. The only way to verify whether Eq. 4.15 holds is to do the measurement.

Figure 4.23 shows the graphs for a collision between two arbitrary carts. To get the momentum values shown in Figure 4.23*b*, I multiplied the x component of the velocity of each cart by the cart's inertia determined by *independently* letting each cart collide with the inertial standard. The change in the x component of the momentum of cart 1 can be obtained by multiplying its inertia ($m_1 = 0.36\ \text{kg}$) with the x components of the initial and final velocities read off from Figure 4.23*a* ($v_{1x,i} = 0$ and $v_{1x,f} = +0.17\ \text{m/s}$):

$$\begin{aligned}\Delta p_{1x} &= m_1(v_{1x,f} - v_{1x,i}) = (0.36\ \text{kg})(+0.17\ \text{m/s} - 0)\\ &= 0.061\ \text{kg}\cdot\text{m/s}.\end{aligned}$$

Figure 4.23 (*a*) Velocity-versus-time graph and (*b*) momentum-versus-time graph of two carts before and after the two collide on a low-friction track. The sum of the momenta is the same before and after the collision. The inertias are $m_1 = 0.36$ kg and $m_2 = 0.12$ kg.

For cart 2 we have $v_{2x,\mathrm{i}} = +0.34$ m/s, $v_{2x,\mathrm{f}} = -0.17$ m/s, and $m_2 = 0.12$ kg, so

$$\begin{aligned}\Delta p_{2x} &= m_2(v_{2x,\mathrm{f}} - v_{2x,\mathrm{i}}) = (0.12\ \mathrm{kg})(-0.17\ \mathrm{m/s} - 0.34\ \mathrm{m/s}) \\ &= -0.061\ \mathrm{kg \cdot m/s}.\end{aligned}$$

Because the two changes in momentum are equal in magnitude and of opposite sign, they add up to zero: $\Delta p_{1x} + \Delta p_{2x} = 0$. Consequently the momentum of the system comprising the two carts does not change:

$$\Delta\vec{p} \equiv \Delta\vec{p}_1 + \Delta\vec{p}_2 = \vec{0}. \tag{4.16}$$

Repeating the experiment with another pair of carts or changing the initial velocities always yields the same result: The momentum of the system comprising any two colliding objects is not changed by the collision. The collision merely transfers some momentum from one cart to the other—one gains a certain amount of momentum, and the other loses the same amount.

4.12 (*a*) How much momentum is transferred in the collisions in Figure 4.23? (*b*) Is this momentum transferred from cart 1 to cart 2, or in the opposite direction?

Experiments show that *any* interaction between two objects—not just collisions—transfers momentum from one object to the other. The sum of the momenta of the interacting objects, however, never changes. No interactions or other phenomena have ever been observed where momentum is created out of nothing or destroyed. We must therefore conclude that momentum is conserved:

Momentum can be transferred from one object to another, but it cannot be created or destroyed.

This statement is one of the most fundamental principles of physics and is often referred to as the **conservation of momentum.**

For an isolated system, conservation of momentum means

$$\Delta\vec{p} = \vec{0} \quad (\text{isolated system}). \tag{4.17}$$

For a system that is not isolated, we have

$$\Delta\vec{p} = \vec{J}, \tag{4.18}$$

QUANTITATIVE TOOLS

where $\vec{J}$ represents the transfer of momentum from the environment to the system. The quantity $\vec{J}$ is called the **impulse** delivered to the system. Like momentum, impulse is a vector and has SI units of kg · m/s. Depending on its direction relative to the momentum, the impulse can increase or decrease the magnitude of the momentum of the system. $\vec{J}$ therefore represents what we called "input" and "output" in Section 4.4.

4.13 (*a*) What is the magnitude of the impulse delivered to cart 1 in Figure 4.23? (*b*) Write the impulse delivered to cart 1 in vector form. (*c*) Does the fact that the change in the momentum of cart 1 is nonzero mean that momentum is not conserved?

Equation 4.18, which we shall use extensively throughout this book, is called the **momentum law.** This equation embodies conservation of momentum because it tells us that the momentum of a system can change only due to a transfer of momentum to the system ($\vec{J}$). If momentum were not conserved, then the right side of this equation would need to contain an additional term to account for changes in momentum due to the creation or destruction of momentum. For an isolated system the impulse is zero, $\vec{J} = \vec{0}$, and the momentum law takes on the form of Eq. 4.17.

EXAMPLE 4.8 Bounce

A 0.20-kg rubber ball is dropped from a height of 1.0 m onto a hard floor and bounces straight up. Assuming the speed with which the ball rebounds from the floor is the same as the speed it has just before hitting the floor, determine the impulse delivered by the floor to the rubber ball.

❶ **GETTING STARTED** I define the ball to be my system in this problem. The impulse delivered to the ball is then given by the change in its momentum (Eq. 4.18). I need to develop a way to determine this change in momentum.

❷ **DEVISE PLAN** To solve this problem I need to first determine the velocity of the ball just before it hits the floor. I therefore break the problem into two parts: the downward fall of the ball and its collision with the floor. I can use Eq. 3.15 to determine the time interval it takes the ball to fall from its initial height (assuming the ball is initially at rest). As it falls, the ball undergoes constant acceleration, so I can use Eq. 3.10 to calculate its velocity just before it hits the floor and, because its speed is not changing as it rebounds, I also know its velocity after it bounces up. Knowing the velocities, I can calculate the ball's momentum before and after the bounce using Eq. 4.7. The change in momentum then gives the impulse according to Eq. 4.18.

❸ **EXECUTE PLAN** From Eq. 3.15 I see that it takes an object $t = \sqrt{2h/g} = \sqrt{2(1.0\text{ m})/(9.8\text{ m/s}^2)} = 0.45$ s to fall from a height of 1.0 m. Choosing the positive x axis pointing upward and substituting this result into Eq. 3.10, I obtain for the x component of the velocity of the ball just before it hits the floor:

$$v_{x,\text{f}} = 0 + (-9.8\text{ m/s}^2)(0.45\text{ s})^2 = -2.0\text{ m/s}.$$

Now that I know the ball's velocity just before it hits the ground I can obtain the x component of the momentum of the ball just before it hits the ground by multiplying the ball's velocity by its inertia: $p_{x,\text{i}} = (0.20\text{ kg})(-2.0\text{ m/s}) = -0.40\text{ kg}\cdot\text{m/s}$. (I use the subscript i to indicate that this is the initial momentum of the ball before the collision with the floor.) If the ball rebounds with the same speed, then the x component of the momentum after the collision with the floor has the same magnitude but opposite sign: $p_{x,\text{f}} = +0.40\text{ kg}\cdot\text{m/s}$. The change in the ball's momentum is thus

$$\begin{aligned}\Delta p_x &= p_{x,\text{f}} - p_{x,\text{i}} = +0.40\text{ kg}\cdot\text{m/s} - (-0.40\text{ kg}\cdot\text{m/s}) \\ &= +0.80\text{ kg}\cdot\text{m/s}.\end{aligned}$$

The interaction with the ground changes the momentum of the ball, making it rebound. The ball does not constitute an isolated system, and the change in its momentum is due to an impulse delivered by Earth to the ball. To determine the impulse, I substitute the change in momentum of the ball into Eq. 4.18:

$$\vec{J} = \Delta\vec{p} = \Delta p_x\hat{\imath} = (+0.80\text{ kg}\cdot\text{m/s})\,\hat{\imath}.$$ ✔

❹ **EVALUATE RESULT** The x component of the velocity of the ball just before it hits the floor is negative because the ball moves downward, in the negative x direction. After the collision it moves in the opposite direction, and consequently the x components of the changes in velocity and momentum are both positive, as I calculated. Because the x component of the change in the ball's momentum is positive, the impulse is directed upward (in the positive x direction). This makes sense because this impulse changes the direction of travel of the ball from downward to upward.

Because the momentum law takes on the simplest form for an isolated system, we shall usually try to choose an isolated system (unlike the above example). In such a case, we can write out the $\Delta\vec{p}$ term in Eq. 4.17:

$$\vec{p}_f = \vec{p}_i \quad \text{(isolated system)}. \tag{4.19}$$

In this form, the momentum law states that the initial and final values of the momentum of an isolated system are equal. For two colliding (or otherwise interacting) objects moving along the x axis, Eqs. 4.17 and 4.19 become

$$\Delta p_{1x} + \Delta p_{2x} = 0 \quad \text{(isolated system)} \tag{4.20}$$

and

$$p_{1x,f} + p_{2x,f} = p_{1x,i} + p_{2x,i} \quad \text{(isolated system)}. \tag{4.21}$$

Equations 4.20 and 4.21 are equivalent: Eq. 4.20 states that any change in momentum in one object is made up by a change of the same magnitude but in the opposite direction in the other object; Eq. 4.21 states that the sum of the momenta is the same before and after the collision. Which of these two equations you use in solving a problem is a matter of convenience.

4.14 (*a*) Are the changes in velocity in Figure 4.23*a* equal in magnitude? Why or why not? (*b*) Determine the velocity changes of the carts and verify that $m_1/m_2 = -\Delta v_{2x}/\Delta v_{1x}$ in Figure 4.23*a*. (*c*) Determine the initial and final momenta of the two carts. (*d*) What is the momentum of the system before the collision? (*e*) After the collision? (*f*) Are the momentum changes equal in magnitude and opposite in direction? Why or why not?

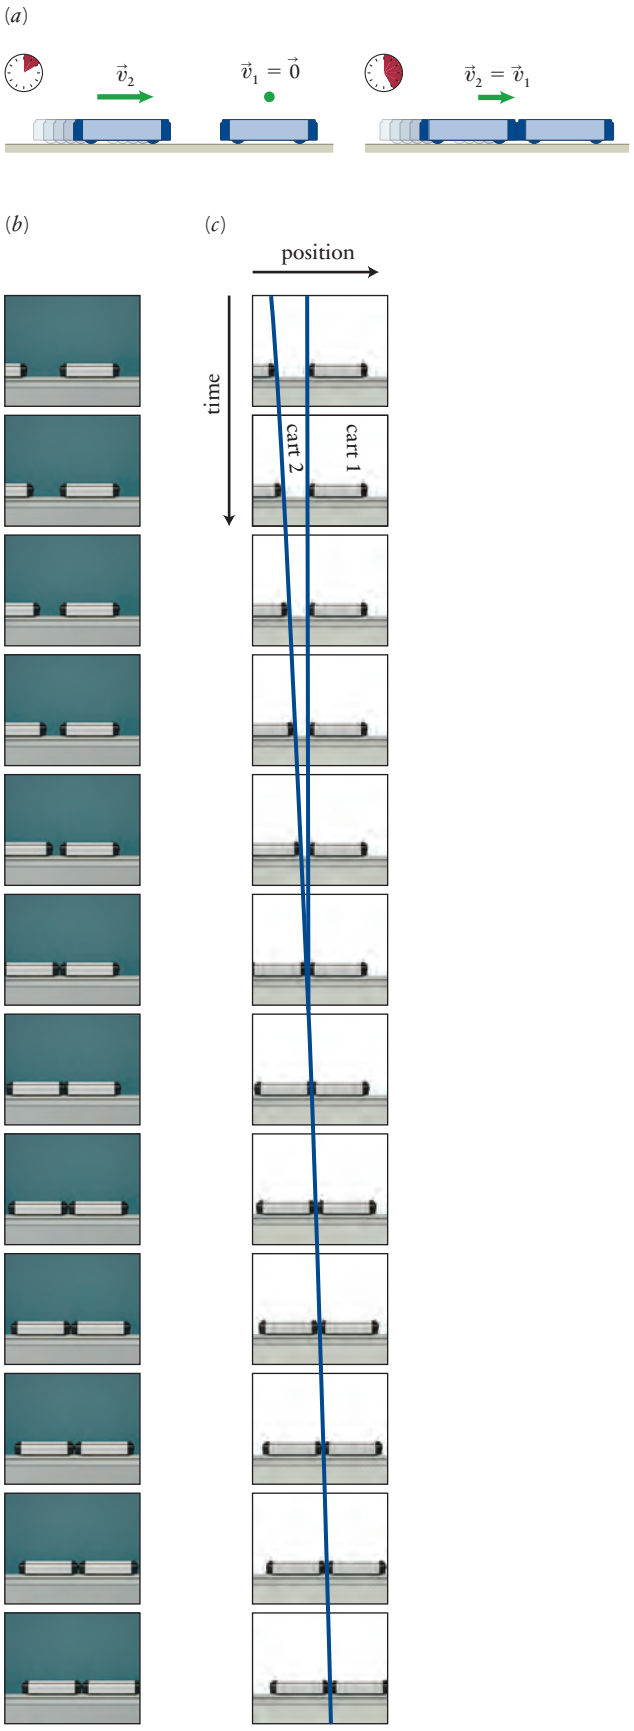
To convince you of the fundamental importance of the conservation of momentum, let me show you something else. Suppose we let carts 1 and 2 of Figure 4.23 collide with the same initial velocities as before, but this time we put something sticky between them, so that they remain locked together once they hit each other, as in **Figure 4.24**. The velocities of the two carts *after* the collision must now be identical.

4.15 (*a*) Do the two carts in Figure 4.24 still constitute an isolated system like the carts in Figure 4.23? (*b*) What does your answer to part *a* imply about the momentum of the system comprising the two carts after the collision?

As you saw in the preceding checkpoint, the system of the two carts is isolated and so the momentum of the system should not change. **Figure 4.25*a*** on page 140 shows graphically that the final velocity of the combined carts is somewhere between the values of the two initial velocities. Before the collision, cart 1 is at rest and the x component of the velocity of cart 2 is $+0.34$ m/s; after the collision, both carts move at $v_{x,f} = +0.085$ m/s. The x component of the momentum of the system before the collision is thus $p_{1x,i} + p_{2x,i} = 0 + (0.12\ \text{kg})(0.34\ \text{m/s}) = 0.041\ \text{kg}\cdot\text{m/s}$. After the collision, the x component of the momentum of the system is $p_{1x,f} + p_{2x,f} = (0.36\ \text{kg})(0.085\ \text{m/s}) + (0.12\ \text{kg})(0.085\ \text{m/s}) = 0.031\ \text{kg}\cdot\text{m/s} + 0.010\ \text{kg}\cdot\text{m/s} = 0.041\ \text{kg}\cdot\text{m/s}$. The data indeed confirm that the momentum of the system does not change.

Note that the before-collision parts of Figures 4.23*a* and 4.25*a* are identical. The after-collision parts of these two figures are quite different from each other, however. Yet even with these two entirely different outcomes—the carts in Figure 4.23 flying off in opposite directions after colliding and those in Figure 4.25 sticking together—the momentum of the system does not change in both cases:

$$\vec{p}_i = \vec{p}_f \quad \text{(isolated system)}. \tag{4.22}$$



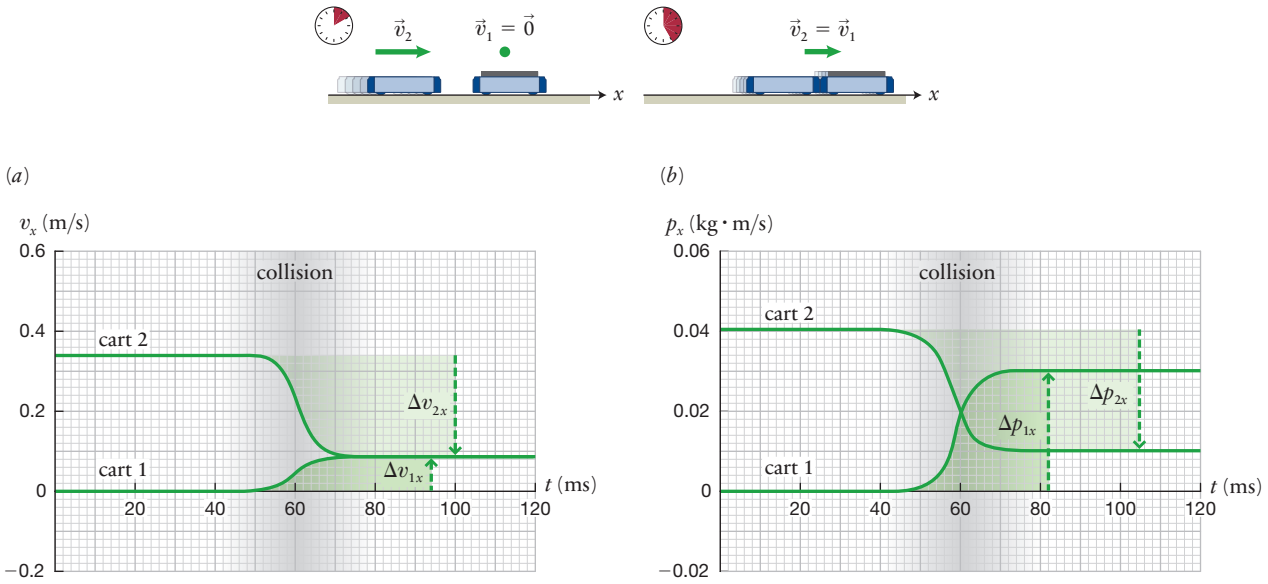


Figure 4.24 (*a*) Two identical carts collide and stick together on a low-friction track. (*b*) High-speed video sequence of such a collision. The length of track visible in each frame is 0.40 m. (*c*) Curves indicating the positions of the rear of cart 1 and the front of cart 2 superimposed on the sequence.

Figure 4.25 (*a*) Velocity-versus-time graph and (*b*) momentum-versus-time graph for the carts of Figure 4.24. Notice that the sum of the momenta is again the same before and after the collision. The inertia of cart 1 is 0.36 kg, and that of cart 2 is 0.12 kg.

The momentum law is not confined to two objects. Suppose we put *three* objects in motion on a low-friction track such that they all end up colliding with one another. Let 1 first collide with 2 and then 2 with 3 (you can pick whatever sequence you like). In the first collision, $\vec{p}_1$ and $\vec{p}_2$ change but their sum remains unchanged. In addition, the sum of all three momenta remains unchanged because nothing has happened to $\vec{p}_3$ yet. When 2 and 3 collide, $\vec{p}_2$ and $\vec{p}_3$ change but the sum $\vec{p}_2 + \vec{p}_3$ does not change. So again, the momentum of the system comprising all three remains constant. In other words, throughout the two collisions, the momentum of the system comprising all three objects, $\vec{p}$, remains unchanged:

$$\vec{p}_{\mathrm{i}} = \vec{p}_{1,\mathrm{i}} + \vec{p}_{2,\mathrm{i}} + \vec{p}_{3,\mathrm{i}} = \vec{p}_{1,\mathrm{f}} + \vec{p}_{2,\mathrm{f}} + \vec{p}_{3,\mathrm{f}} = \vec{p}_{\mathrm{f}} \quad \text{(isolated system)}. \qquad (4.23)$$

This argument can be extended to any number of objects and any number of collisions or interactions.

That we can apply conservation of momentum to predict the final momentum of carts colliding on a low-friction track may seem like nothing special because you are indeed unlikely to encounter this situation outside the physics classroom. Conservation of momentum has much broader applications, however, because it governs *everything that happens in the universe*. Conservation of momentum applies to atoms and elementary particles at the subatomic scale, to stars and galaxies at the cosmic scale, and to everything in between. Next time you fly in an airplane consider this: you are moving forward because of conservation of momentum. The aircraft engines "throw air backward" so the airplane and the passengers move forward. Conservation of momentum is used to solve many science and engineering problems: from calculating the forces of impact during vehicle collisions, to the trajectories of satellites, to the load-carrying capabilities of artificial limbs.

QUANTITATIVE TOOLS

4.16 A railroad car moves at speed v_{i} on a track toward three other railroad cars at rest on the track. All the cars are identical, and each stationary car is some distance from the others. The moving car hits the first stationary car and locks onto it. Then the two hit the second stationary car, lock onto that one, and so on. When all four cars have locked onto one another, what is the speed v_{f} of the four-car train?

Chapter Summary

Inertia (Sections 4.1–4.3, 4.5)

Concepts *Friction* is the resistance to motion that one surface encounters when moving over another surface. In the absence of friction, objects moving along a horizontal track keep moving without slowing down.

Inertia is a measure of an object's tendency to resist a change in its velocity. Inertia is determined entirely by the type of material of which the object is made and by the amount of that material contained in the object. Inertia is related to *mass*, and for this reason we use the symbol m to represent it. The SI unit of inertia is the **kilogram** (kg).

Quantitative Tools If an object of unknown inertia m_u collides with an inertial standard of inertia m_s, the ratio of the inertias is related to the changes in the velocities by

$$\frac{m_u}{m_s} \equiv -\frac{\Delta v_{sx}}{\Delta v_{ux}}. \tag{4.1}$$

Systems and momentum (Sections 4.4, 4.6–4.8)

Concepts A **system** is any object or group of objects that can be separated, in our minds, from the surrounding environment. The **environment** is everything that is not part of the system. You can choose the system however you want, but once you decide to include a certain object in the system, that object must remain a part of the system throughout your analysis.

A system for which there are no external interactions is called an **isolated system.**

An **extensive quantity** is one whose value is proportional to the size or "extent" of the system. An **intensive quantity** is one that does not depend on the extent of the system.

A **system diagram** shows the initial and final conditions of a system.

Quantitative Tools The **momentum** $\vec{p}$ of an object is the product of its inertia and velocity:

$$\vec{p} \equiv m\vec{v}. \tag{4.6}$$

The momentum of a system of objects is the sum of the momenta of its constituents:

$$\vec{p} \equiv \vec{p}_1 + \vec{p}_2 + \cdots. \tag{4.11, 4.23}$$

Conservation of momentum (Sections 4.4, 4.8)

Concepts Any extensive quantity that cannot be created or destroyed is said to be **conserved,** and the amount of any *conserved* quantity in an isolated system is *constant*. Momentum is a conserved quantity, and therefore the momentum of an isolated system is constant. The momentum can be transferred from one object to another in the system, but the momentum of the system cannot change.

Quantitative Tools The momentum of an isolated system is constant:

$$\Delta\vec{p} = \vec{0}. \tag{4.17}$$

Another way to say this is that for an isolated system, the initial momentum is equal to the final momentum:

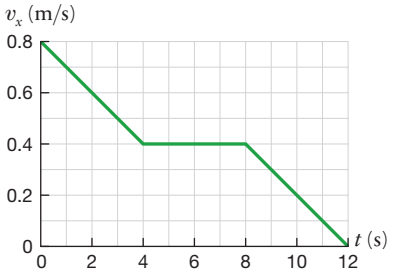
$$\vec{p}_i = \vec{p}_f. \tag{4.22}$$

The **impulse** $\vec{J}$ delivered to a system is equal to the change in momentum of the system:

$$\vec{J} = \Delta\vec{p}. \tag{4.18}$$

For an isolated system, $\vec{J} = \vec{0}$.

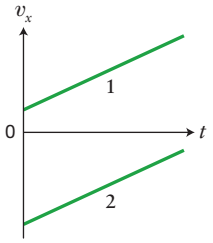
Questions and Problems



For instructor-assigned homework, go to Mastering Physics

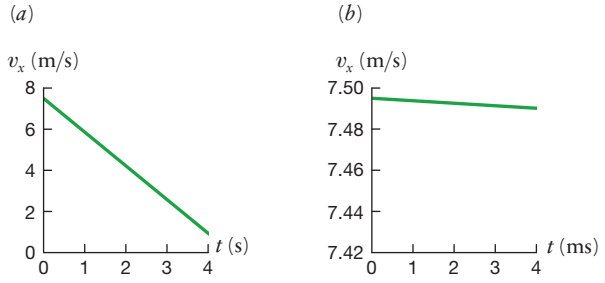
Dots indicate difficulty level of problems: • = *easy*, •• = *intermediate*, ••• = *hard*; CR = *context-rich problem.*

4.1 Friction



1. Two identical boxes A and B slide over the same rough floor. Box B stops over a distance twice as long as that needed for box A. Assuming a constant frictional force F acting in both cases, compare the initial velocities of the two boxes. •
2. Figure P4.2 shows the velocity of a block of wood as a function of time. The block is sliding over a horizontal surface. Describe the physical processes that led to this graph. •

Figure P4.2



3. The velocity-versus-time graph in Figure P4.3 shows the motion of two different objects sliding across a horizontal surface. Could the change in the x component of velocity with time be attributed to friction in each case? ••

Figure P4.3

4. Consider the two velocity-versus-time graphs shown in Figure P4.4. Are the motions represented by these curves best described as similar or as different? Is the effect of friction on the motion plausibly more pronounced in one case? ••

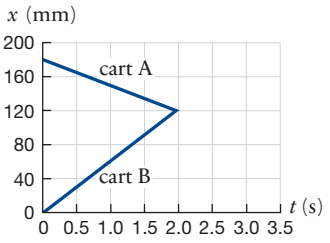


Figure P4.4

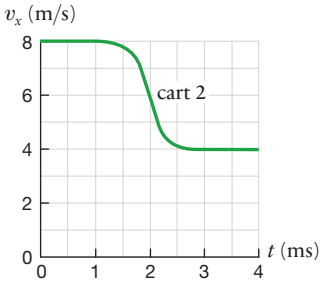
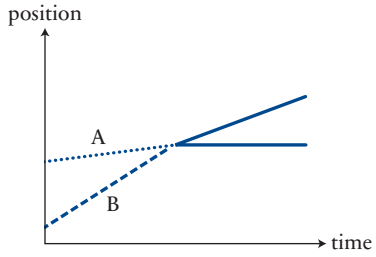
4.2 Inertia



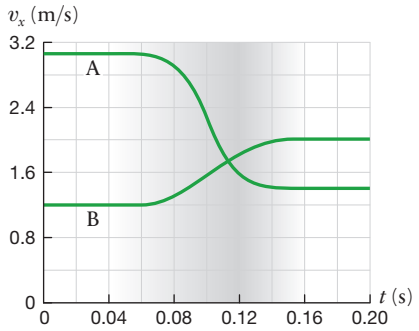
5. Two objects collide on a low-friction track. Object 1 experiences a magnitude of change in velocity $|\Delta\vec{v}_1| = 3$ m/s, while object 2 has $|\Delta\vec{v}_2| = 1$ m/s. How do the inertias of these two objects compare? •
6. In a collision experiment, the ratio of the velocity change between two carts of equal inertia is found to equal 1. What happens to this ratio if the experiment is repeated in the following conditions? (*a*) The inertia of each cart is doubled, and the same initial velocities are used. (*b*) The original value of inertia is used, and the initial velocities of the carts are doubled. •
7. Two carts of equal inertia are moving in opposite directions toward each other. Figure P4.7 represents the positions of the carts until they collide. Sketch the positions of the carts after the collision. •

Figure P4.7



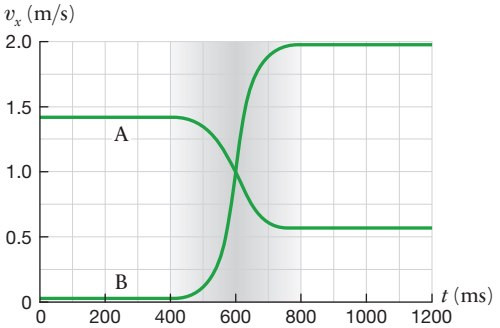
8. Cart 1 initially at rest is struck by cart 2, which has twice the inertia of cart 1. Figure P4.8 shows the velocity of cart 2 as a function of time. Complete the graph by adding the velocity of cart 1 during the same time. ••

Figure P4.8



9. Figure P4.9 is the position-versus-time graph for a collision, along a straight line, between two identical amusement-park bumper cars A and B. The inertias of the passengers are different. (*a*) Which post-collision solid line is a continuation of the dotted line for car A? Which is a continuation of the dashed line for car B? (*b*) Which car contains the passenger having the greater inertia? ••

Figure P4.9



10. Figure P4.10 shows the $v_x(t)$ curves for two carts, A and B, that collide on a low-friction track. What is the ratio of their inertias? ●●

Figure P4.10

11. Figure P4.11 is a velocity-versus-time graph for two objects, A and B, before and after they collide. Object B is initially at rest. What factor relates the inertias of objects A and B? ●●

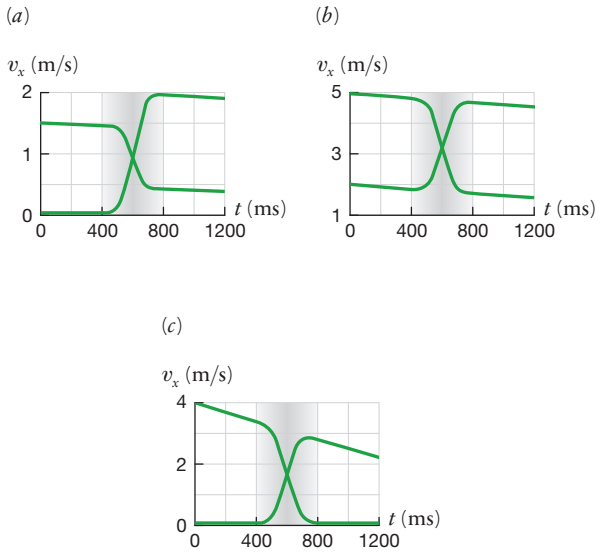


Figure P4.11

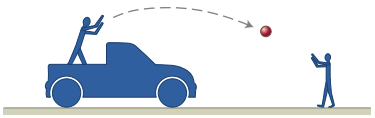
4.3 What determines inertia?

12. There are two 3-L bottles, one filled with water and the other filled with milk. Which one will have higher inertia? ●
13. A goldsmith used a 500-g bar of gold and melted it and molded into a small statue of a Roman god. Comment on the change in the inertia of the gold before and after being molded. ●
14. Five different objects are formed from a constant volume V of different materials, and the objects are placed on various surfaces. Rank the following objects in order of increasing inertia: a cubic lead block on ice, a cubic plastic block on ice, a sphere of lead on ice, a pyramid of plastic on concrete, and a pyramid of lead on concrete. ●
15. During a flood-relief operation, two boxes having same inertia, one filled with polythene tent material and the other one filled with rice packets, are dropped from a helicopter. Which one will reach the ground fast? ●●
16. The engine of a moving spaceship suddenly stopped working. What will happen to the motion of the space ship? ●●
17. The velocity-versus-time graphs in Figure P4.17 all depict the motion of carts that have the same size and shape. The different graphs show motion on different tracks: a smooth icy track, a dusty unpolished track, and a rough damaged track. In one case metal carts are used, in one case plastic cars are used, and in one case one cart of each material is used. The carts may initially be moving in opposite directions, in the same direction, or one may be at rest. For each graph, label the track type, cart type, and initial motion. If you cannot determine a property, state why. ●●

Figure P4.17



4.4 Systems

18. The boiling point of water on top of a mountain reduced to 80 °C compared to 100 °C at the sea level. Is the boiling point of water intensive or extensive? ●
19. You are riding a bus and thinking about the number of passengers on board. (*a*) Is the number of passengers an extensive or intensive quantity? (*b*) Draw a system diagram to help account for the number of passengers. Where is the system boundary? (*c*) Does the number of passengers remain constant? (*d*) Does the number of passengers remain constant as the bus follows its route while its doors stay closed? ●
20. A quart is a unit of volume. (*a*) If you have 1 quart of water in one container and 1 quart of water in another container and you pour all the water from both into a larger container, what volume of water do you end up with? (*b*) Suppose you have a 1-quart container filled with marbles and a large pail containing 1 quart of water. When you dump the marbles into the pail, is the final volume the same as in part *a*? Why or why not? (*c*) Compare the inertias in each case before and after mixing. ●●

21. Figure P4.21 shows a person on a truck throwing a ball to a friend on the ground. In how many ways can you divide these things into a system and an environment? ●●

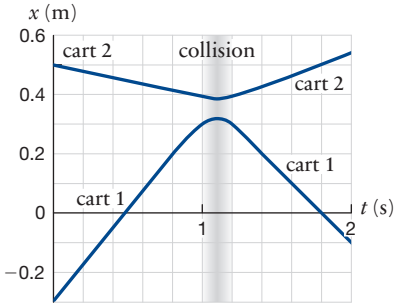


Figure P4.21

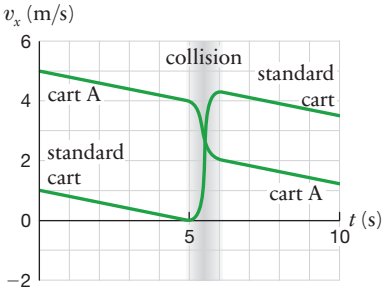
4.5 Inertial standard



22. If two carts collide on a low-friction track, it is possible for both carts to slow down. Yet Eq. 4.1 $\left(\frac{m_u}{m_s} = -\frac{\Delta v_{sx}}{\Delta v_{ux}}\right)$ seems to say that, because inertia is always positive, if one velocity increases, the other must decrease. Explain the apparent discrepancy. ●
23. Cart A, of inertia 1.0 kg, is initially at rest on a low-friction track; cart B, of unknown inertia, has an initial velocity of +3.0 m/s in your coordinate system. After the two carts collide, the final velocities are $\vec{v}_A = +2.0$ m/s and $\vec{v}_B = -3.0$ m/s. What is the inertia of cart B? ●
24. A 1.0-kg cart is initially at rest on a low-friction track. It is hit by a 3-kg cart moving at 0.2 m/s to the left. After the collision, the 3-kg cart continues to move to the left at 0.1 m/s. What is the velocity of the 1-kg cart? ●●
25. A 1-kg standard cart collides with a 5.0-kg cart initially at rest on a low-friction track. After the collision, the standard cart is at rest and the 5.0-kg cart has a velocity of 0.20 m/s to the left. What was the initial velocity of the standard cart? ●●
26. Figure P4.26 is the position-versus-time graph for a collision between two carts on a low-friction track. Cart 1 has an inertia of 1.0 kg; cart 2 has an inertia of 4.0 kg. (*a*) What are the initial and final velocities of each cart? (*b*) What is the change in the velocity of each cart? (*c*) Do the values you calculated in part *b* satisfy Eq. 4.1? (*d*) Draw a velocity-versus-time graph for this collision. (*e*) Does cart 1 have a nonzero acceleration? If so, when, and what is the sign of the acceleration? (*f*) Does cart 2 have a nonzero acceleration? If so, when, and what is the sign of the acceleration? ●●

Figure P4.26

27. The bumper boats at your local theme park each have an inertia of 90 kg. In boat 1 are a man of unknown inertia, a 45-kg woman, and a 3.0-kg dog. In boat 2 are an 80-kg father, a 50-kg mother, and a 30-kg son. Boat 1 collides at 1.5 m/s with boat 2, which is initially at rest. Two seconds after the collision, boat 2 has moved 2.3 m and boat 1 has moved 0.26 m in the opposite direction. (*a*) Taking the initial direction of motion of boat 1 as positive, what is the velocity of each boat after the collision? (*b*) What is the change in velocity of each boat? (*c*) What is the man's inertia? (*d*) If the collision took 0.50 s, what was each boat's average acceleration during the collision? ●●●
28. A 1-kg standard cart collides with a cart A of unknown inertia. Both carts appear to be rolling with significant wheel friction because their velocities change with time as shown in Figure P4.28. (*a*) What are the carts' velocities at $t = 0$, $t = 5.0$ s, $t = 6.0$ s, and $t = 10$ s? (*b*) When not colliding, are the carts speeding up or slowing down? (*c*) Is the acceleration of each cart the same before and after the collision? (*d*) What is the inertia of cart A? ●●●

Figure P4.28

4.6 Momentum

29. At what speed should a 0.02-kg bullet be shot to have the same momentum as a 0.45-kg soccer ball kicked at 80 km/hr by a professional player? ●
30. The student next to you says, "Momentum is inertia times velocity. That means momentum is proportional to inertia, and so things with more inertia have more momentum." What would you say to the student to clarify the matter? ●
31. A 2000-kg car is moving at the same speed as a 6000-kg bus, as they go on adjacent lanes along the same level road. Both drivers apply their brakes, stopping over the same distance to avoid a red light. Which vehicle will have a bigger change in its momentum? ●
32. A bicyclist coasting along a road at speed v collides with a grasshopper flying in the opposite direction at the same speed. The grasshopper sticks to the bicyclist's helmet. Make a sketch showing (*a*) the two velocity vectors and the two momentum vectors before the collision, (*b*) the velocity and momentum vectors after the collision, and (*c*) the velocity change and the momentum change for the bicyclist and for the grasshopper. ●●
33. Is it possible for the momentum of a system consisting of two carts on a low-friction track to be zero even if both carts are moving? ●●

34. A 1.0-kg standard cart A collides with a 0.10-kg cart B. The x component of the velocity of cart A is +0.60 m/s before the collision and +0.50 m/s after the collision. Cart B is initially traveling toward cart A at 0.40 m/s, and after the collision the x component of its velocity is +0.60 m/s. What are (*a*) the x component of the change in the momentum of A, (*b*) the x component of the change in the momentum of B, and (*c*) the sum of these two x components of the changes in momentum? ••

35. You're rolling solid rubber balls on the kitchen floor. Ball 1 has a density of 1.00×10^3 kg/m^3 and a radius of 25.0 mm. Ball 2 has an unknown density and a radius of 40.0 mm and is initially at rest. You roll ball 1 at an initial speed of 3.00 m/s, and the two balls collide head-on. Ball 1 reverses direction and comes back to you at 2.00 m/s, and after the collision, the speed of ball 2 is 1.00 m/s. With the positive x axis in the direction of ball 1's initial motion, what are (*a*) the magnitudes of the initial and final momenta of ball 1, (*b*) the initial and final momenta of ball 2, and (*c*) the density of ball 2? ••

36. A 1-kg box is accidentally dropped from a third-floor window 7.5 m above the ground. What is the change in its momentum as it strikes the muddy ground, coming to a complete stop? ••

37. From what height would a car have to fall in order for the magnitude of its momentum to equal the magnitude of its momentum when it is moving on a highway at 30 m/s? ••

38. (*a*) Write an expression relating the average acceleration, Δp, and Δt for an object of constant inertia m. (*b*) Given your result in part *a*, what can you say about the magnitude of the acceleration of an object coming to rest after being dropped on a soft bed versus a hard floor? (*c*) Discuss the rationale for airbags in cars. •••

39. You drop a 0.15-kg ball to the floor from a height of 2.0 m, and it bounces to a height of 1.6 m. What is the magnitude of the change in its momentum as a result of the bounce? •••

4.7 Isolated systems

40. When a rifle is fired, it *recoils*, kicking backward into the shooter's shoulder. Why? •

41. A rifle fires a 15-g bullet at 500 m/s and recoils with a speed of 2.5 m/s. What is the inertia of the rifle? •

42. Robert Brown first discovered the random motion of pollen immersed in water through a microscope. When seen with naked eyes, everything seemed to be still, but, upon viewing through a microscope, the random motion of pollen grains was detected. Can you calculate the net momentum of the pollen grains? ••

43. For our solar system, the planets with their moons revolve around the sun with different orbital periods. Even the sun is not static, and it revolves around a spot in the Milky Way galaxy in approximately 250 million years. In that scenario, do you consider our solar system to be an isolated system or not? Justify your answer. ••

44. A car moves with constant velocity on a regular road. Can you say the car is an example of an isolated system? ••

45. In a pairs skating competition, a 75-kg male skater moving at 4.0 m/s collides (gently) with his stationary, 50-kg female partner and raises her in a lift. Neither of them makes a horizontal push at the instant of the pickup. What is the speed of the pair after the collision? (Hint: The vertical motion of the female has no bearing on the question.) ••

46. A girl wearing ice skates stands in a skating rink and throws her backpack to a bench just off the ice. (*a*) If her skates are aligned parallel to the direction of the throw, what happens to her as a result? (*b*) When the backpack lands on the bench, it stops. Does the skater stop at the same instant? If not, where does the momentum of the skater-backpack system go? ••

47. A cart moving on a low-friction track has a momentum of 6 kg · m/s to the right. At the end of the track is a wall. (*a*) What is the momentum of the system that consists of the cart and the wall? (*b*) After the cart collides with the wall, the cart's momentum is 6 kg · m/s to the left. What is the wall's momentum after impact, from the track's perspective? (*c*) Is the system defined in part *a* an isolated system? Why doesn't the wall move? ••

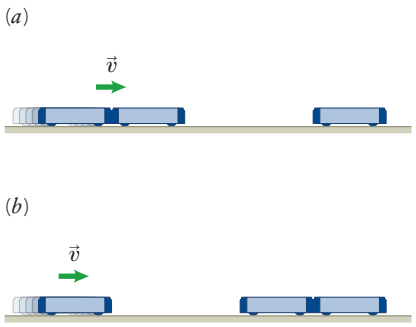
4.8 Conservation of momentum

48. What does conservation of momentum say about the motion of a single cart that doesn't collide with anything as it moves on a low-friction track? •

49. The three carts described in the accompanying table collide simultaneously. What is the momentum of the system of three carts (*a*) before the collision and (*b*) after the collision? (*c*) Is the system of three carts isolated during the collision, according to these data? •

	Momentum p_x (kg · m/s)	
Cart	Before collision	After collision
1	+6.0	−4.0
2	−2.0	+2.0
3	−3.0	+3.0

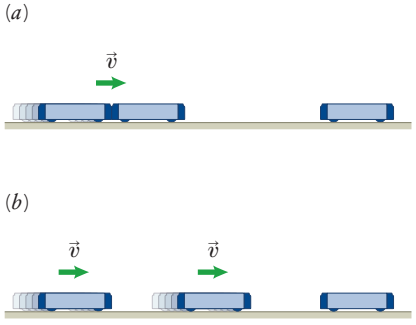
50. Two carts collide on a track. The initial momentum of cart 1 is +5 kg · m/s $\hat{\imath}$ and its final momentum is −3 kg · m/s $\hat{\imath}$. The initial momentum of cart 2 is −4 kg · m/s $\hat{\imath}$ and its final momentum is +4 kg · m/s $\hat{\imath}$. Would you say that the track is a low-friction track? Explain. •



51. Two carts A and B collide on a low-friction track. Measurements show that their initial and final momenta are $\vec{p}_{A,i} = (+10 \text{ kg} \cdot \text{m/s})\,\hat{\imath}$, $\vec{p}_{A,f} = (+2.0 \text{ kg} \cdot \text{m/s})\,\hat{\imath}$, $\vec{p}_{B,i} = (-4.0 \text{ kg} \cdot \text{m/s})\,\hat{\imath}$, and $\vec{p}_{B,f} = (+4.0 \text{ kg} \cdot \text{m/s})\,\hat{\imath}$. (*a*) What is the change in the momentum of each cart during the collision? (*b*) What is the sum of these changes in momenta? (*c*) Is this collision consistent with conservation of momentum? Why or why not? ••

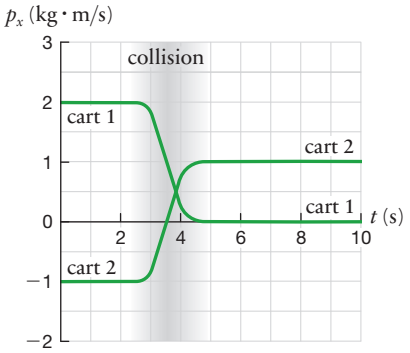
52. Two carts A and B collide on a low-friction track. Measurements show that their initial and final momenta are $\vec{p}_{A,i} = (+3.0 \text{ kg} \cdot \text{m/s})\,\hat{\imath}$, $\vec{p}_{A,f} = (+1.0 \text{ kg} \cdot \text{m/s})\,\hat{\imath}$, $\vec{p}_{B,i} = (+2.0 \text{ kg} \cdot \text{m/s})\,\hat{\imath}$, and $\vec{p}_{B,f} = (-6.0 \text{ kg} \cdot \text{m/s})\,\hat{\imath}$. (*a*) What is the change in the momentum of each cart during the collision? (*b*) What is the sum of these changes in momenta? (*c*) Is this collision consistent with the physics you know? Why or why not? ••

53. A moving object collides with an object at rest. (*a*) Is it possible for both objects to be at rest after the collision? (*b*) Is it possible for just one object to be at rest after the collision? If so, which one? Ignore any effects due to friction. ••



54. Estimate the magnitude of impulse that you impart to a nail (and to whatever the nail is buried in) when you hit it with a hammer. ●●
55. A 1200-kg automobile traveling at 15 m/s collides head-on with a 1600-kg automobile traveling at 10 m/s in the opposite direction. (*a*) Is it possible to predict the velocities of the cars after the collision? (*b*) Is it possible to predict the value that any pertinent physical quantity has immediately after the collision? ●●
56. A 2.0-kg cart and a 3.0-kg cart collide on a low-friction track. The 3.0-kg cart is initially moving at 1.0 m/s to the right, but after the collision it is moving at 5.0 m/s to the right. After the collision, the 2.0-kg cart is moving to the right at 3.0 m/s. (*a*) What was the 2.0-kg cart's initial velocity? (*b*) What would your answer be if, other quantities being unchanged, the 3.0-kg cart were initially moving to the left at 1.0 m/s? ●●
57. Warmly dressed in several layers of clothing, you are standing at the center of a frozen pond. There is not enough friction to permit you to walk to the edge of the pond. How can you save yourself? (Never mind how you got to the center of the pond.) ●●
58. On an icy day, a driver swerves into the opposite lane and gets into a head-on collision with another car whose inertia is twice that of his. Both cars have the same speed when they hit and lock together. What fraction of their original speed do they have when moving together? ●
59. An 80-kg physicist and a friend are ice-skating. The physicist, distracted, collides from behind at 7.0 m/s with his friend, who is skating at 5.0 m/s in the same direction. After the collision, the physicist continues in the same direction at 4.0 m/s, but his friend is now moving (still in the same direction) at 8.0 m/s. What is her inertia? ●●
60. A 1500-kg car is being driven with the top open at 30 m/s $\hat{\imath}$ when a 50-g golf ball moving at -10 m/s $\hat{\imath}$ hits the cushioned seat and stops immediately. What is (*a*) the car's momentum and (*b*) the ball's momentum before the collision? (*c*) What is the change in the car's velocity due to the collision? ●●
61. Sledding down a hill, you are traveling at 10 m/s when you reach the bottom. You (inertia 70 kg) then move across horizontal snow toward a 200-kg boulder but jump off the sled (inertia 5.0 kg) the instant before it hits the boulder. The boulder is sitting on *very* slick ice and moves freely when the sled hits it. The sled bounces back, moving at 6.0 m/s. (*a*) At what speed does the boulder move after the sled hits it? (*b*) If you stayed on the sled, what would your momentum be just before you hit the boulder? (*c*) Suppose you and the sled hit the boulder and continue forward after the collision at 2.0 m/s. Would the boulder's after-collision speed be higher or lower than the speed you calculated in part *a*? ●●
62. A fire hose sprays water against a burning building. The stream of water has cross-sectional area A and density ρ and moves with speed v toward the building. Assume the water splatters against the building without reflecting. What magnitude of impulse does the stream of water deliver during the time interval Δt? ●●
63. Playing pool, you send the cue ball head-on (that is, along the line joining the centers of the two balls) into the stationary 8 ball, and the cue ball stops as a result of the collision. (*a*) Describe the momentum of each ball before and after the collision. (*b*) Show that your answer to part *a* is consistent with Eq. 4.18, $\Delta\vec{p} = \vec{J}$. (Note: Assume that pool balls have identical inertias.) ●●
64. Three identical carts on a low-friction track have putty on their ends so that they stick together when they collide. In Figure P4.64*a*, two carts already stuck together and moving with speed v are about to collide with the third cart initially at rest. In Figure P4.64*b*, the single cart moving with the same speed v is about to collide with the two carts already stuck together and initially at rest. In which case is the final velocity of the trio of carts greater? ●●

Figure P4.64

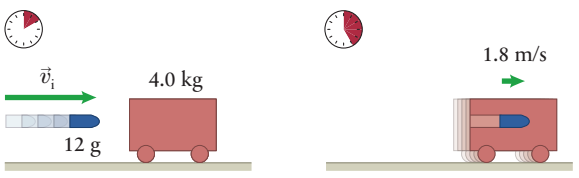


65. A 20-kg mail cart rolls on a smooth floor at 5 m/s when a 2-kg package drops from a shelf directly above and comes to rest in the cart. What is the change in the cart's speed? ●●
66. Three identical carts on a low-friction track have putty on their ends so that they stick together when they collide. In Figure P4.66*a*, two carts already stuck together and moving at speed v collide with the single cart initially at rest. In Figure P4.66*b*, there are two collisions: First the center cart, moving at speed v, collides with the cart on the right (and they stick together). Then the left cart, moving at speed v, collides with those two carts. In which case is the final speed of the three carts greater? ●●

Figure P4.66

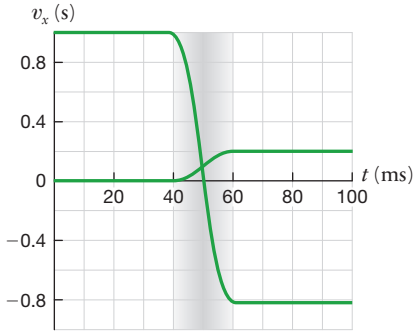
67. Figure P4.67 is a momentum-versus-time graph for a collision between two carts. Carts 1 and 2 have inertias of 1.0 kg and 3.0 kg, respectively. What are the x components of the initial and final velocities of (*a*) cart 1 and (*b*) cart 2? (*c*) What are the momentum changes $\Delta\vec{p}_1$ and $\Delta\vec{p}_2$? (*d*) Do the values you calculated in part *c* satisfy Eq. 4.18, $\Delta\vec{p} = \vec{J}$? (*e*) Draw the velocity-versus-time graph for this collision. (Hint: You can do this by making some simple changes to Figure P4.67.) •••

Figure P4.67



68. Carts A and B collide on a low-friction track. Rank, from largest to smallest, the following four collisions according to the magnitude of the change in the momentum of cart B, which has twice the inertia of cart A. (*a*) A initially moving right at 1.0 m/s, B initially stationary; stick together on impact. (*b*) A initially stationary, B initially moving left at 1.0 m/s; stick together on impact. (*c*) A initially moving right at 1.0 m/s; after impact, A moving left at 0.33 m/s, B moving right at 0.67 m/s. (*d*) A initially moving right at 1.0 m/s, B initially moving left at 1.0 m/s; stick together on impact. •••
69. A red cart and a green cart, both traveling at speed v on a low-friction track, approach each other head-on. The red cart is moving to the right; the green cart, whose inertia is three times that of the red cart, is moving to the left. A black cart that has a spring on its left end and putty on its right end sits on the track between the two moving carts. The moving carts hit the black cart at the same instant. After the collision, the red cart moves left at speed v, and the green and black carts move together at speed $v/5$. What is the inertia of the black cart, expressed as a multiple of the inertia of the red cart? •••
70. A 1.0-kg standard cart collides on a low-friction track with cart A. The standard cart has an initial x component of velocity of +0.40 m/s, and cart A is initially at rest. After the collision the x component of velocity of the standard cart is +0.20 m/s and the x component of velocity of cart A is +0.60 m/s. After the collision, cart A continues to the end of the track and rebounds with its speed unchanged. Before the carts collide again, you drop a lump of putty onto cart A, where it sticks. After the second collision, the x component of velocity of the standard cart is −0.20 m/s and the x component of velocity of cart A is +0.40 m/s. What is the inertia of the putty? •••
71. A 400-kg shipboard cannon fires a 20-kg ball at 60 m/s. The cannon's resulting recoil speed across the deck is regarded as excessive. How much inertia (in the form of sandbags, say) must be added to the cannon if its recoil speed must be reduced to 2.0 m/s? •••
72. You point a tennis-ball serving machine straight up and put a piece of plastic wrap across the top of the barrel, placing a 10-g marble on top of the barrel. When a 58-g tennis ball in the machine is fired, it sends the marble into the air. The marble rises 200 m above the barrel mouth, and the tennis ball rises 54 m. Neglecting the plastic wrap, what is the ball's launch speed? •••

Additional Problems



73. The momentum ratio of a cannon grapeshot and rifle bullet is 3:100. If the mass of the grapeshot is 5 kg and the mass of the bullet is 0.05 kg, find the relation between their velocities. •
74. A 30,000-kg trailer truck approaches a one-lane bridge at 2.2 m/s; a 2400-kg minivan approaches the bridge from the other direction at 30 m/s. Which vehicle has a momentum of greater magnitude? •
75. You and a friend are bowling. She rolls her 4.5-kg ball at 10 m/s; you roll your ball at 8.0 m/s. What inertia must your ball have if its momentum is to be the same as hers? •
76. Two identical carts collide in three experiments on a low-friction track. In each case, cart A initially has velocity $\vec{v}$ and cart B is at rest. Sketch the velocity-versus-time graph for each cart (*a*) if the carts stick together after the collision, (*b*) if cart A is stationary after the collision, and (*c*) if cart A has velocity $-\vec{v}/10$ after the collision. ••
77. Draw diagrams that show the initial and final velocity vectors and the initial and final momentum vectors when a rapidly moving golf ball hits (*a*) a golf ball at rest and (*b*) a basketball at rest. In each case, assume that the golf ball moves along the line connecting the centers of the two balls. ••
78. The position of a certain airplane during takeoff is given by $x = \frac{1}{2}bt^2$, where $b = 2.0\ \text{m/s}^2$ and $t = 0$ corresponds to the instant at which the airplane's brakes are released at position $x = 0$. The empty but fueled airplane has an inertia of 35,000 kg, and the 150 people on board have an average inertia of 65 kg. What is the magnitude of the airplane's momentum 15 s after the brakes are released? ••
79. A bullet of inertia m_{bullet} is fired horizontally at a speed $v_{\text{bullet,i}}$ into a stationary wooden block of inertia m_{block} lying on a low-friction surface. The bullet passes through the block and emerges with a speed $v_{\text{bullet,f}}$. Determine the final speed of the block in terms of the given quantities. ••
80. The speed of a bullet can be measured by firing it at a wooden cart initially at rest and measuring the speed of the cart with the bullet embedded in it. Figure P4.80 shows a 12-g bullet fired at a 4.0-kg cart. After the collision, the cart rolls at 1.8 m/s. What is the bullet's speed before it strikes the cart? ••

Figure P4.80

81. The World War II–era rocket launcher called the bazooka was essentially a tube open at both ends. On the basis of momentum considerations, how is the firing of a bazooka different from the firing of a cannon, which is a tube open at one end only? ●●
82. In a football game, a 95-kg player carrying the ball can run the 50-m dash in 5.5 s. Two opponents are available to stop him with a head-on tackle. One opponent has an inertia of 110 kg and a 50-m time of 6.6 s; the other has an inertia of 90 kg and a 50-m time of 5.1 s. Which has the better chance of stopping the 95-kg player, and why? ●●
83. In the days before rocketry, some people argued that rocket engines would not work in space because there is no atmosphere for the exhaust to push against. Even today, some people think that a rocket requires a launch pad to push against in order to lift off. Refute such arguments with an argument based on momentum considerations. ●●
84. In some collisions, the velocity of one participant changes little while that of the other changes a lot, as Figure P4.84 illustrates. (*a*) In which direction (positive or negative) are the objects moving before the collision? (*b*) After the collision? (*c*) What is the ratio of the inertia of the larger object to the inertia of the smaller object? (*d*) Does friction play an important role in this collision? ●●

Figure P4.84

85. When a truck and a car both moving with same velocities collide head on, the car gets the maximum damage. Justify. ●●
86. A single-stage rocket is in deep space coasting at $v_{\text{rocket,i}} = 2.0 \times 10^3$ m/s. It fires its engine, which has an exhaust speed of $v_{\text{exhaust}} = 1.0 \times 10^3$ m/s. What is the rocket's speed $v_{\text{rocket,f}}$ after it has lost one-third of its inertia by exhausting burned fuel? Assume that the fuel is ejected all at once. ●●
87. In the process of moving out of your house, you are dropping stuff out a second-floor window to a friend 4.0 m below. You are about to drop a 6.0-kg stereo speaker when you begin to worry that catching anything that has a momentum greater than 50 kg · m/s might be harmful. ●●● CR
88. You are in mission control in Florida, supervising a probe on its way to Mars. The most recent report indicates that the probe will soon need to fire a quick burst of its booster rocket to increase its speed by 5.2 m/s. You know that the spent fuel is ejected at a speed $v_{\text{fuel}} = 800 \text{ m/s} - v_i$, where v_i is the initial speed of the probe before firing, and that 10% of the probe's inertia is currently fuel. Your main worry is whether enough fuel is left for landing maneuvers. ●●● CR
89. You have just launched your new hot-air balloon and are hovering 30.0 m above the ground. As you are checking equipment, the burner fails. You know that if you do nothing, the balloon will descend with a constant acceleration of 1.50 m/s^2, and that the balloon's basket will be seriously damaged if it hits the ground with a momentum of 2850 kg · m/s or more. The combined inertia of the balloon, basket, and all equipment and fuel is 195 kg, not counting yourself (85.0 kg) and ten 5.00-kg sandbags carried as ballast. You make some quick calculations and take action to save the day. ●●● CR
90. A single gas molecule of inertia m is trapped in a box and travels back and forth with constant speed v between opposite walls A and B a distance ℓ apart. At each collision with a wall, the molecule reverses direction without changing speed. Write algebraic expressions for (*a*) the magnitude of the change in momentum of the molecule as it collides with wall B, (*b*) the amount of time that elapses between collisions with wall B, (*c*) the number of collisions per second the molecule makes with wall B, and (*d*) the change in momentum undergone by wall B, per second, as a result of these collisions. ●●●
91. Consider a two-stage rocket made up of two engine stages, each of inertia m when empty, and a payload of inertia m. Stages 1 and 2 each contain fuel of inertia m, so that the rocket's inertia before any fuel is spent is $5m$. Each stage exhausts fuel at a speed $v_{\text{fuel}} = v_{\text{ex}} - v_{\text{i}}$, where v_{ex} is the speed of the exhaust relative to the rocket and v_{i} is the speed of the rocket relative to the ground at the instant the fuel is spent. The rocket is initially at rest in deep space. Stage 1 fires, ejects its fuel all at once, and then detaches from the remainder of the rocket. The same process is repeated with stage 2. (*a*) What is the final speed of the payload? (Hint: Determine the speed of the rocket after stage 1 fires. Then, because stage 1 is detached from the rocket, *redefine the system* to include only the payload and stage 2, and determine the speed of the rocket after stage 2 fires.) (*b*) Now consider another rocket of inertia $5m$ but with only a single engine stage, of inertia $2m$, carrying fuel of inertia $2m$. What is the final speed of the payload in this case? (*c*) Which design yields a higher payload speed: two stage or single stage? Why? ●●●

CONCEPTS

QUANTITATIVE TOOLS

Now that we know about conservation of momentum, can we determine the final velocities of two colliding objects if the only things we know are the initial velocities and the fact that the momentum is conserved? The answer is *no* if our only tool is the momentum law. In the collisions represented in Figures 4.23 and 4.25, for instance, momentum is unchanged in both cases, and yet the two outcomes are definitely not the same. So knowing only that momentum remains constant isn't enough. We need additional information in order to predict future positions and velocities. In the process of looking for this additional information, we shall develop another conservation law—the law of conservation of *energy*.

5.1 Classification of collisions

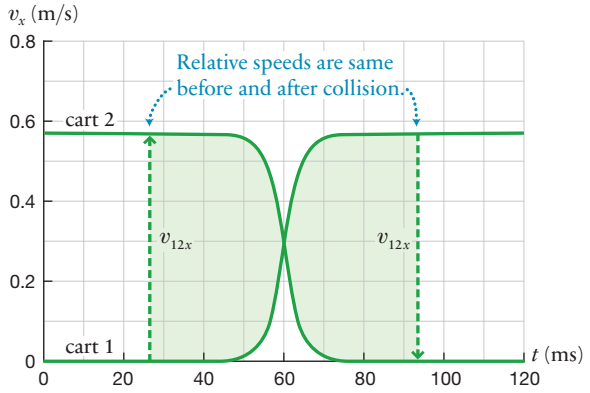
If you look at the velocity-versus-time graphs in Chapter 4, you will notice that the velocity difference in the two carts, $\vec{v}_2 - \vec{v}_1$, in most cases has the same magnitude before and after the collision. **Figure 5.1** shows two graphs of collisions we considered in Chapter 4 and highlights the velocity difference before and after the collision. This difference is the **relative velocity** of the carts: $\vec{v}_{12} \equiv \vec{v}_2 - \vec{v}_1$ is the velocity of cart 2 relative to cart 1 and $\vec{v}_{21} \equiv \vec{v}_1 - \vec{v}_2$ is the velocity of cart 1 relative to cart 2. The subscript in the relative velocity symbol is always shown with the object we are studying printed last: v_{12} is the velocity *of cart 2* and v_{21} is the velocity *of cart 1*. (We cannot use Δ here because we reserve that symbol to denote the change in a *single* quantity; now we are dealing with the difference between the same quantity for two different objects.)

The magnitude of the relative velocity is called the **relative speed.** Thus $v_{12} \equiv |\vec{v}_2 - \vec{v}_1|$ is the speed of cart 2 (last subscript in v_{12}) relative to cart 1. For motion along the x axis, the relative speed is the absolute value of the difference in the x components of the velocities: $v_{12} \equiv |v_{2x} - v_{1x}|$. Note that the sequence of the subscripts for relative speeds does not matter: $v_{12} \equiv |v_{2x} - v_{1x}| = |v_{1x} - v_{2x}| = v_{21}$ (the speed of cart 2 relative to cart 1 is equal to the speed of cart 1 relative to cart 2).

A collision in which the relative speed before the collision is the same as the relative speed after the collision is called an **elastic collision.** Collisions between hard objects are, for the most part, elastic collisions. For instance, a superball bouncing off a hard floor bounces up with nearly the same speed with which it came down. Thus the relative speed of floor and ball does not change, and the collision is elastic.

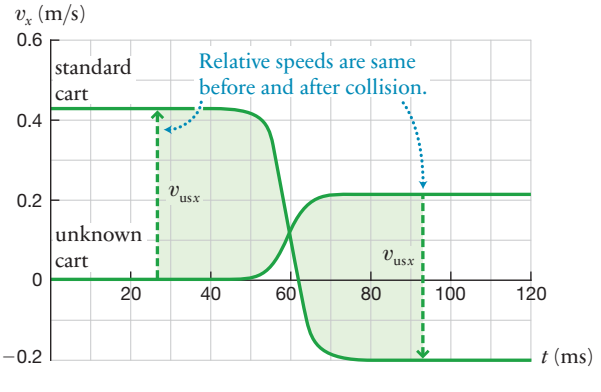
5.1 Two cars are moving along a highway with neither one accelerating. Is their relative speed equal to the difference between their speeds? Why or why not?

Any collision for which the relative speed after the collision is lower than that before the collision is called an **inelastic collision.** If you drop a tennis ball to the floor, it rebounds with a lower speed than it had when it hit the floor. The relative speed is reduced, and the collision is inelastic.



A special type of inelastic collision is one in which the two objects move together after the collision so that their relative speed is reduced to zero. We call this special case a **totally inelastic collision.** Imagine dropping a ball of dough to the floor. Splat! The dough sticks to the floor, and the relative speed of dough and floor is reduced to zero. The collision in Figure 4.25 is another example of an inelastic collision.

As you might imagine, whether a collision is elastic, inelastic, or totally inelastic depends on the properties of the objects involved. However, if we know what happens to the relative speed in a collision, we can use that knowledge together with conservation of momentum to determine the final velocities.



CONCEPTS

Figure 5.1 Velocity-versus-time graphs of (*a*) two identical carts colliding on a low-friction track, with one of the carts initially at rest, and (*b*) a standard cart colliding with a cart of unknown inertia that is initially at rest. Notice that for both collisions the relative speeds of the two carts are the same before and after the collision.

(*a*) Moving cart collides with identical cart at rest

(*b*) Standard cart collides with cart of unknown inertia at rest

EXERCISE 5.1 Classifying collisions

Are the following collisions (for motion along the x axis) elastic, inelastic, or totally inelastic? (*a*) A red billiard ball moving at $v_{rx,i} = +2.2$ m/s hits a white billiard ball initially at rest. After the collision, the red ball is at rest and the white ball moves at $v_{wx,f} = +1.9$ m/s. (*b*) Cart 1 moving along a track at $v_{1x,i} = +1.2$ m/s hits cart 2 initially at rest. After the collision, the two carts move at $v_{1x,f} = +0.4$ m/s and $v_{2x,f} = +1.6$ m/s. (*c*) A piece of putty moving at $v_{px,i} = +22$ m/s hits a wooden block moving at $v_{bx,i} = +1.0$ m/s. After the collision, the two move at $v_{x,f} = +1.7$ m/s.

SOLUTION (*a*) The initial relative speed is $v_{wr,i} = |v_{rx,i} - v_{wx,i}| = |+2.2 \text{ m/s} - 0| = 2.2$ m/s; the final relative speed is $v_{wr,f} = |v_{rx,f} - v_{wx,f}| = |0 - 1.9 \text{ m/s}| = 1.9$ m/s, lower than the initial relative speed, which means the collision is inelastic. ✔

(*b*) $v_{12i} = |v_{2x,i} - v_{1x,i}| = |0 - (+1.2 \text{ m/s})| = 1.2$ m/s; $v_{12f} = |v_{2x,f} - v_{1x,f}| = |+1.6 \text{ m/s} - (+0.4 \text{ m/s})| = 1.2$ m/s. Because the relative speeds are the same, the collision is elastic. ✔

(*c*) After the collision, both the putty and the block travel at the same velocity, making their relative speed zero. The collision is totally inelastic. ✔

5.2 (*a*) An outfielder catches a baseball. Is the collision between ball and glove elastic, inelastic, or totally inelastic? (*b*) When a moving steel ball 1 collides head-on with a steel ball 2 at rest, ball 1 comes to rest and ball 2 moves away at the initial speed of ball 1. Which type of collision is this? (*c*) Is the sum of the momenta of the two colliding objects constant in part *a*? In part *b*?

5.2 Kinetic energy

Relative speed is not an extensive quantity, and so we cannot develop an accounting scheme for it as we did for momentum in Chapter 4. The trick in studying elastic collisions therefore is to obtain a quantity that allows us to express the fact that the relative speed doesn't change in the form: (something of object 1) + (something of object 2) doesn't change. As I shall show you in Section 5.5, for an object of inertia m moving at speed v this something is the quantity $K = \frac{1}{2}mv^2$, called the object's **kinetic energy** (literally "energy* associated with motion"). Unlike relative speed, which refers to two objects, kinetic energy is associated with a single object. Furthermore, kinetic energy is always positive and independent of the direction of motion (which means that it is a scalar). A ball moving at speed v to the left has exactly the same kinetic energy as the same ball moving at speed v to the right (or any other direction in space). Whenever the speed of an object changes, the kinetic energy changes.

5.3 Is kinetic energy an extensive quantity?

To develop some feel for this new quantity and its relationship to relative speed, let us calculate the kinetic energies of the carts before and after the collisions shown in **Figure 5.2**. The two collisions have identical initial conditions, but one is elastic (Figure 5.2*a*) and the other is totally inelastic (Figure 5.2*b*).

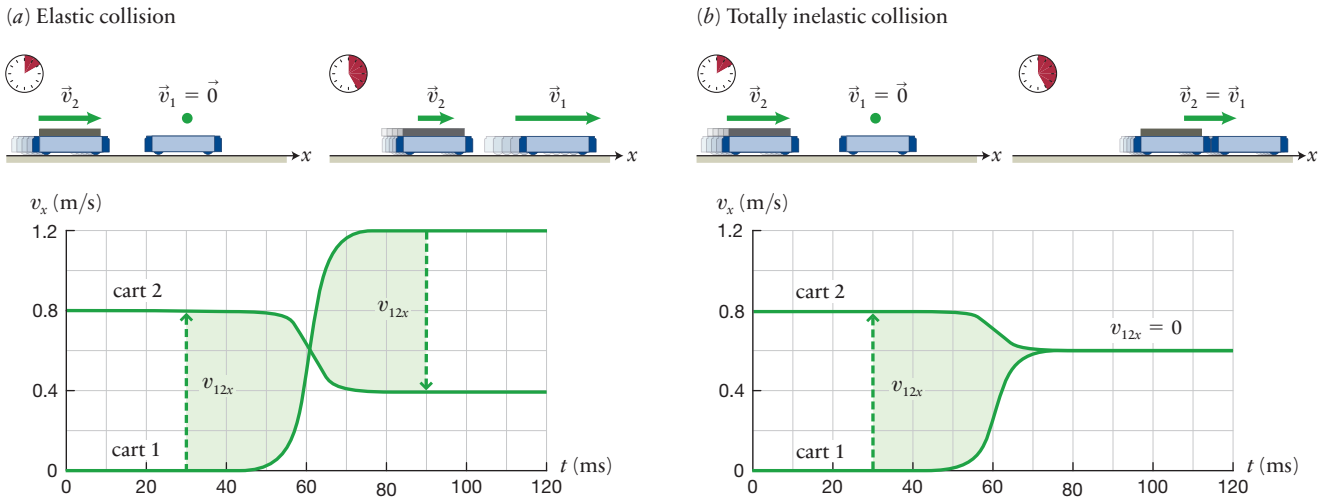


Table 5.1 gives the initial and final kinetic energies of the carts, obtained by reading off the x components of the velocities from the figure. For the elastic collision, where the relative speed doesn't change, the sum of the two kinetic energies before the collision is equal to the sum after the collision: $(0.12 + 0)\ \text{kg}\cdot\text{m}^2/\text{s}^2 = (0.086 + 0.029)\ \text{kg}\cdot\text{m}^2/\text{s}^2$. For the totally inelastic collision, both the relative speed and the sum of the two kinetic energies change.

In general we observe:

In an elastic collision, the sum of the kinetic energies of the objects before the collision is the same as the sum of the kinetic energies after the collision.

*For now think of "energy" as the capacity to do things like accelerating and heating objects. We shall develop a more complete picture of what energy is in later sections and chapters.

Figure 5.2 Velocities for elastic and inelastic collisions between two carts. Cart 1 has inertia 0.12 kg, and cart 2 has inertia 0.36 kg.

CONCEPTS

Table 5.1 Kinetic energy in elastic and totally inelastic collisions

	Inertia m (kg)	ELASTIC Velocity v_x (m/s)		ELASTIC Kinetic energy $\frac{1}{2}mv^2$ (kg·m²/s²)		TOTALLY INELASTIC Velocity v_x (m/s)		TOTALLY INELASTIC Kinetic energy $\frac{1}{2}mv^2$ (kg·m²/s²)	
		before	*after*	*before*	*after*	*before*	*after*	*before*	*after*
Cart 1	0.12	0	+1.2	0	0.086	0	+0.60	0	0.022
Cart 2	0.36	+0.80	+0.40	0.12	0.029	+0.80	+0.60	0.12	0.065
Relative speed		**0.80**	**0.80**			**0.80**	**0**		
Kinetic energy of system				**0.12**	**0.12**			**0.12**	**0.086**

In Section 5.5 we'll see that this statement is equivalent to the requirement that the relative speed remains the same.

For problems involving elastic collisions, we now have two tools: the momentum conservation law, which tells us that the momentum of an isolated system doesn't change, and the fact that the relative speed of the colliding objects doesn't change (or, alternatively, the fact that the kinetic energy of the system doesn't change). Let's now use both tools in an example.

EXAMPLE 5.2 Carts colliding

(*a*) Is the collision in Figure 4.23 elastic, inelastic, or totally inelastic? How can you tell? (*b*) Verify your answer by comparing the initial kinetic energy of the two-cart system with the final kinetic energy.

1 GETTING STARTED In Figure 4.23, it looks as if the initial and final relative speeds are the same, which makes the collision elastic. The problem asks me to confirm this fact by calculating the initial and final kinetic energies of the system.

2 DEVISE PLAN To answer part *a*, I need to determine the initial and final relative speeds of the carts from the velocities, which I get from Figure 4.23*a*: $v_{1x,i} = 0$; $v_{2x,i} = +0.34$ m/s; $v_{1x,f} = +0.17$ m/s; $v_{2x,f} = -0.17$ m/s. To answer part *b*, I use $K = \frac{1}{2}mv^2$. The inertias of the carts are given in the figure caption: $m_1 = 0.36$ kg and $m_2 = 0.12$ kg.

3 EXECUTE PLAN (*a*) $v_{12i} = |v_{2x,i} - v_{1x,i}| = |(+0.34\text{ m/s}) - 0| = 0.34$ m/s; $v_{12f} = |v_{2x,f} - v_{1x,f}| = |(-0.17\text{ m/s}) - (+0.17\text{ m/s})| = 0.34$ m/s. The relative speed is unchanged, and thus the collision is elastic. ✔

(*b*) The initial values are

$$K_{1i} = \tfrac{1}{2}m_1v_{1i}^2 = \tfrac{1}{2}(0.36\text{ kg})(0)^2 = 0$$

$$K_{2i} = \tfrac{1}{2}m_2v_{2i}^2 = \tfrac{1}{2}(0.12\text{ kg})(0.34\text{ m/s})^2 = 0.0069\text{ kg·m}^2/\text{s}^2$$

so

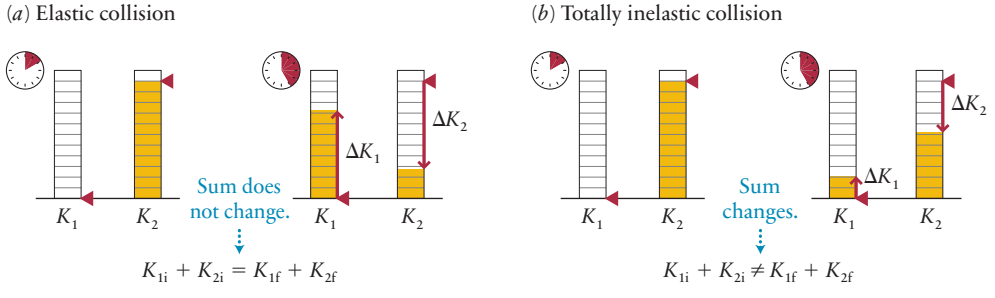
$$K_i = K_{1i} + K_{2i} = 0.0069\text{ kg·m}^2/\text{s}^2.$$

The final values are

$$K_{1f} = \tfrac{1}{2}m_1v_{1f}^2 = \tfrac{1}{2}(0.36\text{ kg})(0.17\text{ m/s})^2 = 0.0052\text{ kg·m}^2/\text{s}^2$$

$$K_{2f} = \tfrac{1}{2}m_2v_{2f}^2 = \tfrac{1}{2}(0.12\text{ kg})(-0.17\text{ m/s})^2 = 0.0017\text{ kg·m}^2/\text{s}^2$$

so $K_f = (0.0052\text{ kg·m}^2/\text{s}^2) + (0.0017\text{ kg·m}^2/\text{s}^2)$
$= 0.0069\text{ kg·m}^2/\text{s}^2$,



which is the same as before the collision, as it should be for an elastic collision. ✔

4 EVALUATE RESULT Because I've reached the same conclusion—the collision is elastic—using two approaches, I can be pretty confident that my solution is correct.

CONCEPTS

Because kinetic energy is a scalar extensive quantity, bar diagrams are a good way to visually represent changes in this quantity. **Figure 5.3**, for example, shows the initial and final kinetic energies of the carts in the two collisions of Figure 5.2. Before the collision, only cart 2 has kinetic energy; after the collision, both carts have kinetic energy. For the elastic collision (Figure 5.3*a*), the

Figure 5.3 Bar diagrams representing the initial and final kinetic energies of the carts for the collisions shown in Figure 5.2. (*a*) The sum of the kinetic energies does not change for the elastic collision because the changes are equal and opposite. (*b*) The sum of the kinetic energies changes for the totally inelastic collision: The change in K_1 is small but positive; the change in K_2 is greater but negative.

sum of the kinetic energies after the collision is the same as the sum before the collision because the change in the kinetic energy of cart 1 is the negative of that of cart 2. For the totally inelastic collision (Figure 5.3*b*), the changes in the kinetic energies do not cancel, and so the system's kinetic energy after the collision is not equal to the system's kinetic energy before the collision.

5.4 A moving cart collides with an identical cart initially at rest on a low-friction track, and the two lock together. What fraction of the initial kinetic energy of the system remains in this totally inelastic collision?

Figure 5.4 Before or after? (*a*) Inelastic collisions are an irreversible process. There is no question that the picture was taken *after* the accident because the state of the two cars has changed. (*b*) Elastic collisions are a reversible process. Can you tell whether this picture was taken before or after the ball collided with the racquet?

(*a*) (*b*)

5.3 Internal energy

In both inelastic and totally inelastic collisions, the relative speed changes and therefore the kinetic energy of the system changes. For example, the decrease in the kinetic energy of cart 2 in Figure 5.2*b*, represented by the downward pointing arrow labeled ΔK_2 in Figure 5.3*b*, is larger than the increase in the kinetic energy K_1 of cart 1, resulting in a decrease in the kinetic energy of the stuck-together carts. Where does this kinetic energy go? Does it simply vanish, or does it go elsewhere?

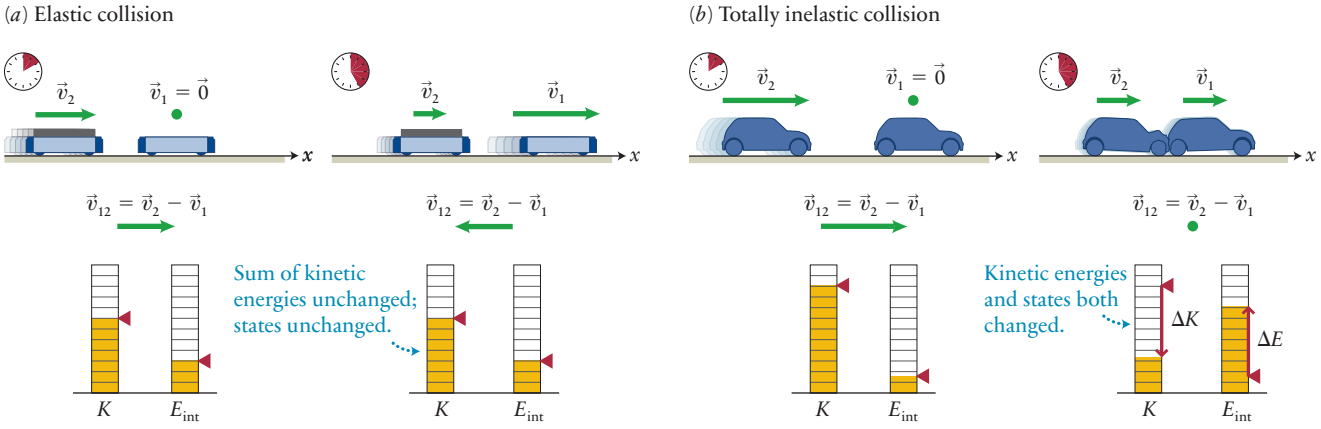
We can determine the answer to this question by looking more closely at inelastic collisions between objects and noticing that changes occur in the **state** of one or both objects. What I mean by *state* is the condition of the object as specified by some complete set of physical parameters: shape, temperature, whatever—*every possible physical variable that defines the object*. In inelastic collisions, objects deform (their shape changes) and heat up (their temperature changes): A ball of dough changes shape as it hits the ground, two cars deform as they collide, hands vigorously clapped together heat up and make sound.

The transformation of a system from an initial state to a final state is called a **process.** Processes cause change (see Section 1.4), and so in physics we aim to understand processes. Collisions that change either the motion or the state of objects are an example of a process. Other examples are the melting of an ice cube, the burning of fuel, the flow of a liquid, and an explosive separation. Initially we focus on collisions because they are easily visualized and we can study what happens in collisions using carts on tracks. As we gain experience, we shall replace collisions with other processes.

In inelastic collisions, the state of the objects after the collision is different from the state before the collision. If I were to make a movie of the ball of dough hitting the ground and then play the movie in reverse, you'd have no trouble telling that the movie was being played in the wrong direction. This is because this inelastic collision involves changes that cannot undo themselves—the dough is flat and at rest after the collision and round and moving before (and never the other way around). The same is true for a collision between two cars: The cars are damaged after the collision and not before, and it is not possible to repair them simply by pulling them apart (**Figure 5.4*a***). After the clapping, your hands are warmer than before, and you cannot cool your hands by "unclapping" them. All these inelastic collisions are **irreversible processes,** which means that the changes that occur in the state of the colliding objects cannot spontaneously undo themselves.

In contrast, viewing a movie of a superball bouncing off the floor or two carts colliding on a low-friction track (without sticking together), you'd be hard pressed to tell whether the movie is playing forward or in reverse. This is because elastic collisions are a **reversible process,** which means there are no permanent changes in the state of the colliding objects. The objects look the same before and after the collision (Figure 5.4*b*).

I have summarized these facts in **Table 5.2**. Notice how a change in the relative speed (and therefore a change in the sum of the kinetic energies) goes hand in hand with a change in the state: The sum of the kinetic energies of two colliding objects doesn't change unless their states change. Let us look at this connection with an eye to formulating a new conservation law.



Suppose we could associate some quantity having the same units as kinetic energy ($\mathrm{kg \cdot m^2/s^2}$) with the state of an object—let's call this quantity the object's **internal energy** (denoted by E_{int}). Suppose further that we could arrange things in such a way that in an inelastic collision the increase in the sum of the internal energies of the colliding objects is equal to the decrease in their kinetic energies. This would mean that in an inelastic collision one form of energy is converted to another form (kinetic to internal) but the sum of the kinetic and internal energies—collectively called the **energy** of the system—doesn't change.

Table 5.2 Elastic and inelastic collisions

Collision type	Relative speed	State
elastic	unchanged	unchanged
inelastic	changed	changed
totally inelastic	changed (becomes zero)	changed

CONCEPTS

Figure 5.5 (*a*) Elastic collision. Because the relative speed of the carts does not change, the sum of the kinetic energies is also unchanged. The carts' states do not change, and so their internal energies are also unchanged. (*b*) Inelastic collision. Because the relative speed changes as a result of the collision, the kinetic energy changes. The cars' states also change, and so the internal energy changes too. For both collisions the sum of the kinetic and internal energies is constant.

In Chapter 7 we'll learn how to specify the state of an object and how to calculate the corresponding internal energy. For now, all we need to do is account for the missing kinetic energy in an inelastic collision by saying:

In any inelastic collision, the states of the colliding objects change, and the sum of their internal energies increases by an amount equal to the decrease in the sum of their kinetic energies.

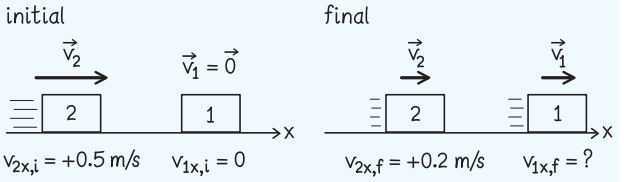
Whenever some kinetic energy disappears in a collision, we can *always* determine changes in state to account for that loss. The big appeal of the relationship between state and internal energy is that we can now say:

The energy of a system of two colliding objects does not change during the collision.

This statement holds for all types of collisions: elastic, inelastic, and totally inelastic. In the elastic collision shown in **Figure 5.5a**, the collision alters the velocities and thus the kinetic energies of both carts. However, the sum of the kinetic energies before and after the collision remains unchanged, as shown by the kinetic energy bars. Because the collision is elastic, there are no changes in the states of the carts, which means their internal energies also remain unchanged, as shown by the internal energy bars. So the energy of the two-cart system does not change.

In the totally inelastic collision of Figure 5.5*b*, the sum of the kinetic energies decreases. Because changes occur in the states—the cars change shape—the internal energies of the carts change as well. The changes in motion and state are such that the energy of the system is the same before and after the collision. We account for the lost kinetic energy by saying that it has been converted to internal energy.

Note that in making the bar diagrams in Figure 5.5, I had to choose some initial value for the internal energies of the colliding objects. As we have no way (yet) of calculating internal energies, the values I chose are arbitrary. At present we are interested only in *changes* in energy, however, and so the initial value is not important.



5.5 A piece of dough is thrown at a wall and sticks to it. Does the internal energy of the dough-wall system increase, decrease, or stay the same?

EXAMPLE 5.3 Internal energy change

A 0.2-kg cart 1 initially at rest is struck by an identical cart 2 traveling at $v_{2x,i} = +0.5$ m/s along a low-friction track. After the collision, the velocity of cart 2 is reduced to $v_{2x,f} = +0.2$ m/s. (*a*) Is the collision elastic, inelastic, or totally inelastic? (*b*) By what amount does the internal energy of the two-cart system change? (*c*) Make a bar diagram showing the initial and final kinetic and internal energies of the two carts.

1 GETTING STARTED I begin by organizing the information given in the problem in a sketch (**Figure 5.6**). To classify the collision, I need to determine the final relative speed, but the final velocity of cart 1 is not given.

Figure 5.6

2 DEVISE PLAN The two-cart system is isolated, and so the momentum of the system does not change, regardless of the type of collision. I can use this information to determine the final velocity of cart 1 and the final relative speed of the carts. By comparing the final and initial relative speeds, I can determine the type of collision. Once I know the initial and final velocities, I can calculate the kinetic energies using $K = \frac{1}{2}mv^2$ and determine what fraction of the initial kinetic energy has been converted to internal energy.

CONCEPTS

3 EXECUTE PLAN (*a*) The initial relative speed is

$$|v_{2x,i} - v_{1x,i}| = |(+0.5\text{ m/s}) - 0| = 0.5\text{ m/s}.$$

To determine $v_{1x,f}$, I apply conservation of momentum to the system. The initial momentum of the system is

$$(0.2\text{ kg})(+0.5\text{ m/s}) + (0.2\text{ kg})(0) = (0.2\text{ kg})(+0.5\text{m/s})$$

and its final momentum is

$$(0.2\text{ kg})(+0.2\text{ m/s}) + (0.2\text{ kg})(v_{1x,f}).$$

Conservation of momentum requires these two momenta to be equal:

$$(0.2\text{kg})(+0.5\text{m/s}) = (0.2\text{kg})(+0.2\text{m/s}) + (0.2\text{kg})(v_{1x,f})$$

$$(+0.5\text{ m/s}) = (+0.2\text{ m/s}) + v_{1x,f}$$

$$v_{1x,f} = +0.3\text{ m/s}.$$

The final relative speed is thus

$$|v_{2x,f} - v_{1x,f}| = |(+0.2\text{ m/s}) - (+0.3\text{ m/s})| = 0.1\text{ m/s},$$

which is different from the initial value. Thus the collision is inelastic. (I know that the collision is not *totally* inelastic because the relative speed has not been reduced to zero.) ✔

(*b*) The initial kinetic energies are

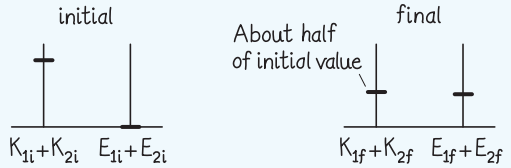
$$K_{1i} = 0$$

$$K_{2i} = \tfrac{1}{2}(0.2\text{ kg})(0.5\text{ m/s})^2 = 0.025\text{ kg}\cdot\text{m}^2/\text{s}^2$$

so $K_i = K_{1i} + K_{2i} = 0.025\text{ kg}\cdot\text{m}^2/\text{s}^2$.

The final kinetic energies are

$$K_{1f} = \tfrac{1}{2}(0.2\text{ kg})(0.3\text{ m/s})^2 = 0.009\text{ kg}\cdot\text{m}^2/\text{s}^2$$



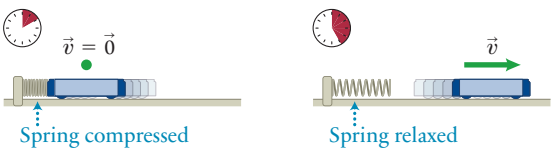
$$K_{2f} = \tfrac{1}{2}(0.2\text{ kg})(0.2\text{ m/s})^2 = 0.004\text{ kg}\cdot\text{m}^2/\text{s}^2$$

so $K_f = K_{1f} + K_{2f} = 0.013\text{ kg}\cdot\text{m}^2/\text{s}^2$.

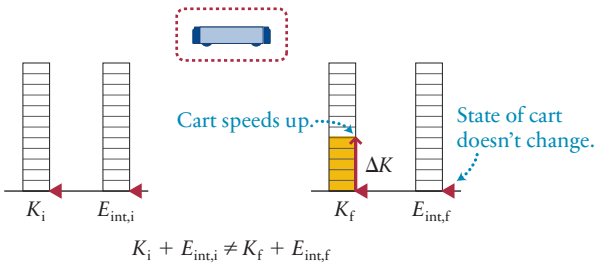
The kinetic energy of the system has changed by an amount $(0.013\text{ kg}\cdot\text{m}^2/\text{s}^2) - (0.025\text{ kg}\cdot\text{m}^2/\text{s}^2) = -0.012\text{ kg}\cdot\text{m}^2/\text{s}^2$. To keep the energy of the system (the sum of its kinetic and internal energies) unchanged, the decrease in kinetic energy must be made up by an increase in internal energy. This tells me that the internal energy of the system increases by $0.012\text{ kg}\cdot\text{m}^2/\text{s}^2$. ✔

(*c*) My bar diagram is shown in **Figure 5.7**. The final kinetic energy bar is about half of the initial kinetic energy bar. Because I don't know the value of the initial internal energy, I set it to zero and make the final internal energy bar equal in height to the difference in the kinetic energy bars. ✔

Figure 5.7

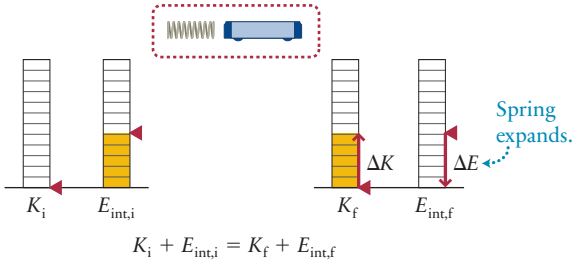


4 EVALUATE RESULT If the collision were elastic, the velocities of the carts would be interchanged and cart 2 would come to a stop (see Figure 4.5). So the collision must be inelastic. Indeed, I found that both the relative speed and the sum of the kinetic energies change in the collision, as expected for an inelastic collision.



We are now in a position to extend the idea of internal energy to other interactions. Consider, for example, a cart initially at rest on a low-friction track set in motion by an expanding spring that is held fixed at one end, as shown in **Figure 5.8*a***. As the cart is accelerated by the spring, the cart's kinetic energy increases but its state doesn't change, and so its energy increases (Figure 5.8*b*). Where did this energy come from? The spring sets the cart in motion, and so it makes sense to assume that the spring transfers energy to the cart. Indeed, the spring expands—its state changes—and so its internal energy changes. If we include the spring in the system and attribute the increase in the cart's kinetic energy to a decrease in the spring's internal energy, we can again arrange things in such a way that the energy of the cart-spring system remains unchanged (Figure 5.8*c*).

Figure 5.8 Initial and final energies for two choices of system.



(*a*) Expanding spring accelerates cart from rest

(*b*) Initial and final energies: system = cart only

(*c*) Initial and final energies: system = cart + spring

CONCEPTS

If we replace the cart in Figure 5.8 with a cart with a different inertia, compress the spring to the same initial state, and then let that cart go, we discover that its final kinetic energy is exactly the same as that of the first cart. So the spring always transfers the same amount of energy as it expands from a given compressed state to its relaxed state *regardless* of the object to which it transfers that energy.

5.6 Think of a few other ways to put the cart of Figure 5.8 in motion. In each case, can you account for the increase in the cart's kinetic energy by either a change in state or a change in motion of another object?

Checkpoint 5.6 suggests that a change in the cart's kinetic energy can always be attributed to either a change in state (and therefore a change in the internal energy) or a change in the motion of another object. Because the states of objects can change in many different ways, we associate different forms of internal energy with different kinds of state change. For example, the internal energy associated with a change in chemical state is called *chemical energy* and the internal energy associated with a change in the temperature of an object is called *thermal energy*. **Table 5.3** lists additional forms of internal energy.

Absolutely everything happening around us entails changes in state and therefore changes in internal energy. Rivers flowing, air masses moving, machines lifting things, people walking, and atoms emitting light can all be expressed in terms of changes in state (and therefore changes in internal energy). More important, we discover that any change in state or motion is always accompanied by a compensating change in state or motion, and we can always attribute energy to these changes in such a way that the energy of the system remains unchanged. In other words, energy cannot be destroyed or created, and energy, like momentum, is a conserved quantity. Indeed, no observation has ever been found to violate the law of **conservation of energy:**

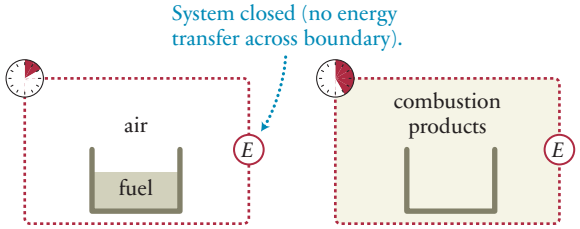
> **Energy can be transferred from one object to another or converted from one form to another, but it cannot be destroyed or created.**

Table 5.3 Various state changes and their associated internal energy

State change	Internal energy
temperature change	thermal energy
chemical change	chemical energy
reversible change in shape	elastic energy
phase transformation	transformation energy

Kinetic energy and all forms of internal energy are thus different manifestations of the same conserved quantity: *energy*.

5.7 (*a*) Is the momentum of the cart-spring system in Figure 5.8 constant? (*b*) Is the system isolated?

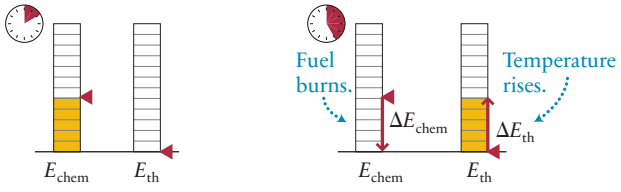


5.4 Closed systems

As Checkpoint 5.7 shows, the system comprising the spring and cart in Figure 5.8 is not isolated. However, no energy is transferred to it, and therefore the energy of the system is constant.* Any system to or from which no energy is transferred is called a **closed system.** An important point to keep in mind is that a closed system need not be isolated (and likewise an isolated system is not necessarily closed). The procedure for choosing a closed system is described in the Procedure box. To see how this procedure works, let's look at the setup in **Figure 5.9**—some fuel (gasoline, say) being burned in a container open to the air.

I begin by making a sketch of the canister with the fuel before and after the combustion (Figure 5.9*a*). The combustion involves two changes in state: a change in the chemical state of the fuel and the air, and a change

Figure 5.9 (*a*) The burning of fuel involves a change in chemical composition and in temperature. (*b*) If we choose a closed system, the change in chemical energy must be compensated by a change in thermal energy.



(*a*) Sketch initial and final conditions, identify changes, choose system

change in motion: none

changes in state:
- chemical state of fuel and air changes
- temperature rises

(*b*) Draw energy bar diagrams for initial and final conditions

*How do I know that no energy is transferred to the cart-spring system? The expanding spring and the accelerating cart do not cause any changes in the state or motion of the environment (the track, Earth, and so on). Consequently the energy of the environment doesn't change, which means that no energy has been transferred from the environment to the system.

CONCEPTS

PROCEDURE: Choosing a closed system

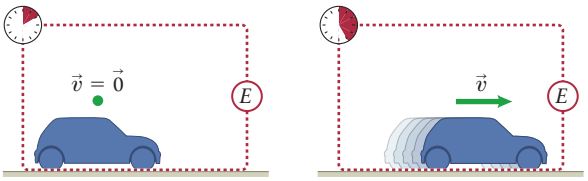
When we analyze energy changes, it is convenient to choose a system for which no energy is transferred to or from the system (a closed system). To do so, follow this procedure:

1. Make a sketch showing the initial and final conditions of the objects under consideration.
2. Identify all the changes in state or motion that occur during the time interval of interest.
3. Choose a system that includes all the objects undergoing these changes in state or motion. Draw a dashed line around the objects in your chosen system to represent the system boundary. Write "closed" near the system boundary to remind yourself that no energy is transferred to or from the system.
4. Verify that nothing in the surroundings of the system undergoes a change in motion or state that is related to what happens inside the system.

Once you have selected a closed system, you know that its energy remains constant.

in the temperature. The fuel and the air immediately surrounding it are what undergo these changes in state, and so I include them in my system. Because there are no other related changes in state, I know that my system is closed and its energy remains constant.

I can now make a bar diagram to represent the changes in energy that take place inside the system (Figure 5.9*b*). The change in the chemical state corresponds to a change in chemical energy, and the change in the temperature corresponds to a change in thermal energy. I therefore draw two bars. The combustion raises the temperature, and so the thermal energy increases. Because the system is closed and its energy remains constant, there must be a decrease in chemical energy that compensates for the increase in thermal energy.



Given that the energy of a closed system remains constant, we can focus on the energy conversions and transfers that happen inside the system. We speak of an *energy conversion* when energy is converted from one form to another. In the combustion illustrated in Figure 5.9, for example, an amount ΔE_{chem} of chemical energy is converted to an equal amount ΔE_{th} of thermal energy. When energy is transferred from one object to another, we speak of an *energy transfer*. An example is shown in Figure 5.3*a*, where energy is transferred from cart 2 to cart 1.

Because we are still lacking the quantitative tools, let me illustrate the transfer and conversion of energy qualitatively with a few examples. By converting some form of internal energy to kinetic energy, we can put objects in motion. For example, a car burns gasoline as it accelerates from rest. If we ignore the effects of friction and air resistance, this situation represents a change in the chemical state of the gasoline and a change in the motion of the car. Chemical energy (a form of internal energy associated with the chemical state) stored in the gasoline is converted to kinetic energy of the car (**Figure 5.10**).

5.8 In describing what's going on in Figure 5.10, I ignored the change in temperature of the engine that accompanies the combustion of the fuel. Make a bar diagram that includes this change in temperature.

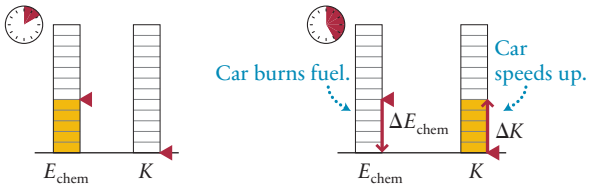


Figure 5.10 (*a*) An accelerating car constitutes a closed system because no changes occur in its environment. (*b*) The increase in the car's kinetic energy can be attributed to a decrease in chemical energy (due to the combustion of fuel).

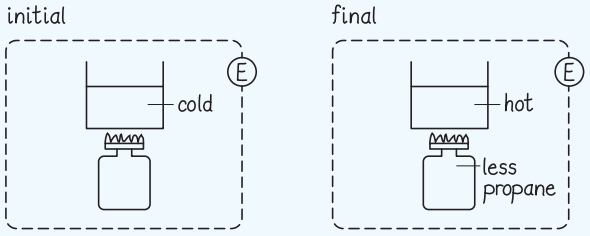
(*a*) Initial and final conditions, changes in state and motion, system

change in motion: car accelerates
change in state: chemical state of fuel changes

(*b*) Energy bar diagrams for initial and final conditions

The generation and consumption of electrical power provide many other examples of energy conversions and transfers. In a coal-burning electrical power plant, coal is burned in a boiler to heat water and convert it to steam. The two complementary changes in state (a change in the chemical state of the coal and a change in the temperature and state of the water) correspond to a conversion of chemical energy to thermal energy. The steam drives a turbine, where the steam cools and a turbine blade spins, and so thermal energy is converted to kinetic energy. The moving turbine drives a generator, which converts the kinetic energy to electrical energy. Power lines transfer energy from the plant to our homes, where it is converted to many forms. Lamps convert electrical energy to light (a form of energy) and thermal energy (lamps get hot), a stereo converts electrical energy to sound energy, and on and on.

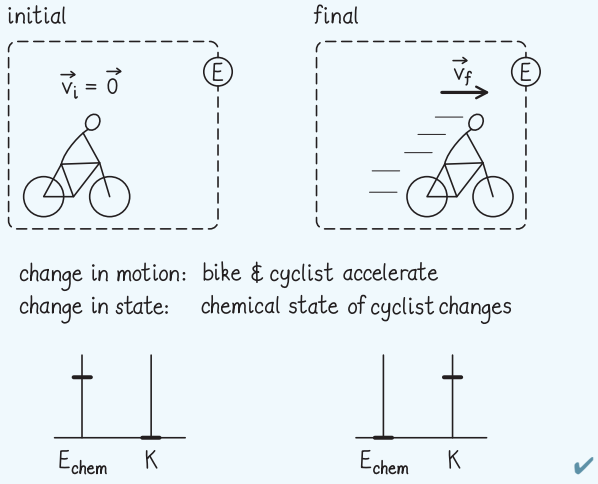
CONCEPTS



EXERCISE 5.4 State changes and internal energy

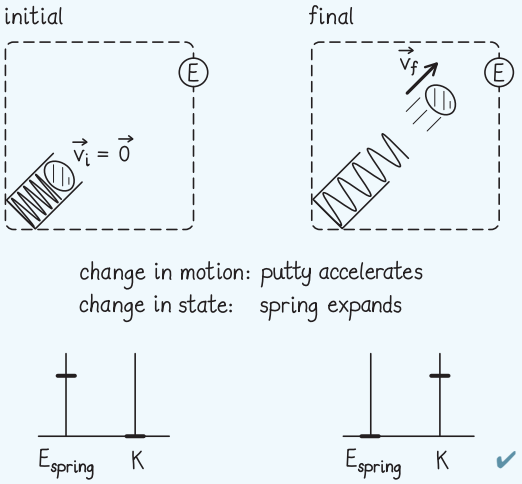
Choose an appropriate closed system and make a bar diagram representing the energy conversions and transfers that occur when (*a*) a pan of water is heated on a propane burner, (*b*) a cyclist accelerates from rest, and (*c*) a spring-loaded gun fires a ball of putty.

SOLUTION For each case, I apply the steps of the Procedure box on page 157. My sketches are shown in the figures.



(*a*) Changes in motion: none. Changes in state: the temperature of the water increases, and the chemical states of the propane and the air change. The bar diagram shows an increase in thermal energy and an equal decrease in chemical energy (**Figure 5.11**). Chemical energy is converted to thermal energy, and in the process energy is transferred from the propane to the water.

Figure 5.11



(*b*) Changes in motion: the bicycle and the cyclist accelerate. Changes in state: the chemical state of the cyclist changes because setting the bicycle in motion requires muscles to contract, a physiological process that involves a complex series of chemical reactions. The bar diagram shows an increase in kinetic energy and an equal decrease in chemical energy (**Figure 5.12**). Chemical energy is converted to kinetic energy of the bicycle and cyclist.

Figure 5.12

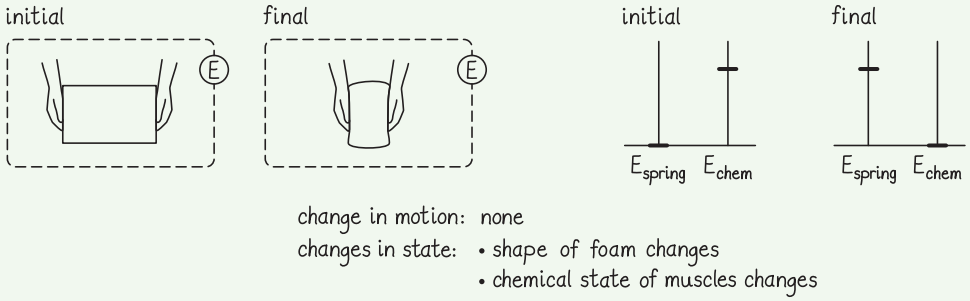
(*c*) Changes in motion: the putty is accelerated. Changes in state: the spring expands. The bar diagram shows a decrease in the elastic energy of the spring and an increase in the kinetic energy of the putty (**Figure 5.13**). As the spring expands, elastic energy is converted to kinetic energy of the putty. ✔

Figure 5.13

We started our study of physics by describing motion in terms of velocities, accelerations, and inertias. Now we have two new quantities, *momentum* and *energy*, and we have found two fundamental conservation laws that allow us to use simple accounting principles to describe changes in motion.

5.9 (*a*) Can the magnitude of the momentum of an object change without a change in the object's kinetic energy? (*b*) Without a change in the object's energy? (*c*) What are your answers to parts *a* and *b* for a system consisting of more than one object?

CONCEPTS



Self-quiz

1. Consider an isolated object at rest in space. The object contains internal energy in some form or another. Is it—in principle—possible to convert the internal energy to kinetic energy so that the object starts to move?
2. Imagine squeezing a piece of foam with your hands. Choose an appropriate closed system and make a bar diagram representing the energy conversions and transfers that occur during the squeezing.
3. When you heat a pot of water on a gas stove, the water temperature increases until the water begins to boil. This change in thermal state from cool water to hot water is due to chemical energy from the burning gas being converted to thermal energy of the water. Once boiling starts, the water temperature stays constant until all the water has turned to steam, even though the burning gas continues to transfer energy to the water. While the water is boiling off and becoming steam, what becomes of the energy released by the burning gas?
4. An electric fan turns electrical energy into wind energy (a form of kinetic energy because it involves moving air). Suppose a blowing fan is suddenly unplugged. Even though the fan no longer receives electrical energy, it continues to blow air while the blades slowly come to a stop. What type of energy is converted to wind energy after the fan is unplugged?

Answers

1. No. Getting the object to move would violate the law of conservation of momentum because the object would start with zero momentum ($\vec{p} = m\vec{v} = m\vec{0} = \vec{0}$) and end with nonzero momentum ($\vec{p} = m\vec{v}$).
2. Draw the foam before and after the squeezing. Two changes in state occur: The shape of the foam changes, and the chemical state of your muscles changes. These two changes in state correspond to changes in the foam's elastic energy and in chemical energy. In your closed system, include the foam and yourself (**Figure 5.14**).

Figure 5.14

3. It goes into changing the phase of the water from liquid to steam.
4. The kinetic energy of the fan blades is converted to wind energy.

5.5 Elastic collisions

As we saw in Section 5.1, we can classify collisions according to what happens to the relative velocity of the two colliding objects. The **relative velocity** of cart 2 relative to cart 1 is defined as

$$\vec{v}_{12} \equiv \vec{v}_2 - \vec{v}_1. \tag{5.1}$$

The relative velocity of cart 1 relative to cart 2 is the negative of this vector:

$$\vec{v}_{21} \equiv \vec{v}_1 - \vec{v}_2 = -\vec{v}_{12}. \tag{5.2}$$

If the magnitude of this relative velocity (the objects' **relative speed** $v_{12} \equiv |\vec{v}_2 - \vec{v}_1|$) is the same before and after the collision, the collision is elastic:

$$v_{12i} = v_{12f} \quad \text{(elastic collision)}. \tag{5.3}$$

For two objects moving along the x axis, we can write this as

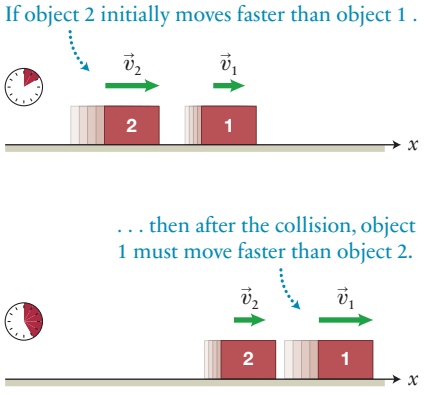
$$v_{2x,i} - v_{1x,i} = -(v_{2x,f} - v_{1x,f}) \quad \text{(elastic collision)}, \tag{5.4}$$

where I have added a minus sign on the right because if object 2 initially moves faster than object 1, object 1 must move faster after the collision (**Figure 5.15**). In other words, in an elastic collision, if $v_{2x,i} > v_{1x,i}$, we must have $v_{2x,f} < v_{1x,f}$. The relative velocity in an elastic collision always changes sign after the collision: $v_{12x,i} = -v_{12x,f}$.

Because we can consider a system made up of two colliding objects to be isolated during the collision, conservation of momentum requires that the momentum of the colliding objects remains unchanged in the collision:

$$m_1 v_{1x,i} + m_2 v_{2x,i} = m_1 v_{1x,f} + m_2 v_{2x,f} \quad \text{(isolated system)}. \tag{5.5}$$

Equations 5.4 and 5.5 allow us to determine the final velocities of the objects, given their initial velocities.



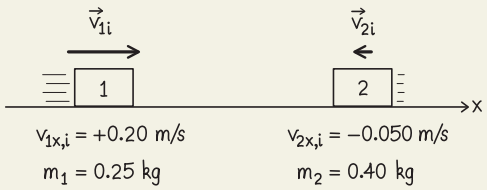


Figure 5.15 A collision between two objects moving in the same direction at different speeds.

EXAMPLE 5.5 Elastic collision

Two carts, one of inertia $m_1 = 0.25$ kg and the other of inertia $m_2 = 0.40$ kg, travel along a straight horizontal track with velocities $v_{1x,i} = +0.20$ m/s and $v_{2x,i} = -0.050$ m/s. What are the carts' velocities after they collide elastically?

❶ **GETTING STARTED** I begin by organizing the information in a sketch to help visualize the situation (**Figure 5.16**). I need to determine the velocities after the collision from the information given, knowing that the collision is elastic.

Figure 5.16

❷ **DEVISE PLAN** To determine the two unknowns $v_{1x,f}$ and $v_{2x,f}$, I need two equations. Because the collision is elastic, I can use Eqs. 5.4 and 5.5.

❸ **EXECUTE PLAN** I begin by solving Eq. 5.4 for $v_{2x,f}$:

$$v_{2x,f} = v_{1x,i} - v_{2x,i} + v_{1x,f}$$

so that I can eliminate $v_{2x,f}$ from Eq. 5.5:

$$m_1 v_{1x,i} + m_2 v_{2x,i} = m_1 v_{1x,f} + m_2(v_{1x,i} - v_{2x,i} + v_{1x,f}).$$

Solving this expression for $v_{1x,f}$ yields

$$v_{1x,f} = \frac{m_1 - m_2}{m_1 + m_2} v_{1x,i} + \frac{2m_2}{m_1 + m_2} v_{2x,i}. \tag{1}$$

QUANTITATIVE TOOLS

Repeating this procedure, I can eliminate $v_{1x,f}$ and solve for $v_{2x,f}$:

$$v_{2x,f} = \frac{2m_1}{m_1 + m_2} v_{1x,i} - \frac{m_1 - m_2}{m_1 + m_2} v_{2x,i}. \quad (2)$$

Substituting the given values into Eqs. 1 and 2 yields $v_{1x,f} = -0.11$ m/s and $v_{2x,f} = +0.14$ m/s. ✔

4 EVALUATE RESULT The final velocities yield the final relative speed $v_{12f} = |(+0.14\,\text{m/s}) - (-0.11\,\text{m/s})| = 0.25\,\text{m/s}$. This value is the same as the initial relative speed $v_{12i} = |(-0.05\,\text{m/s}) - (+0.20\,\text{m/s})| = 0.25\,\text{m/s}$, as required for an elastic collision.

Let me now show how Eqs. 5.4 and 5.5 lead to an expression that shows that the kinetic energy of two colliding objects doesn't change in an elastic collision. Rearranging the terms in Eq. 5.5, I get

$$m_1(v_{1x,i} - v_{1x,f}) = m_2(v_{2x,f} - v_{2x,i}), \quad (5.6)$$

while Eq. 5.4 yields

$$v_{1x,i} + v_{1x,f} = v_{2x,i} + v_{2x,f}. \quad (5.7)$$

Now I multiply the left side of Eq. 5.6 by the left side of Eq. 5.7 and likewise for the right sides to get

$$m_1(v_{1x,i} - v_{1x,f})(v_{1x,i} + v_{1x,f}) = m_2(v_{2x,f} - v_{2x,i})(v_{2x,i} + v_{2x,f}), \quad (5.8)$$

which multiplies out to

$$m_1 v_{1x,i}^2 - m_1 v_{1x,f}^2 = m_2 v_{2x,f}^2 - m_2 v_{2x,i}^2. \quad (5.9)$$

For motion along the x axis, the square of the x component of a velocity is the same as the square of the speed, $v_x^2 = v^2$, and so I can drop all the subscripts x. If I put all the v_i terms on the left and all the v_f terms on the right, I get

$$m_1 v_{1i}^2 + m_2 v_{2i}^2 = m_1 v_{1f}^2 + m_2 v_{2f}^2. \quad (5.10)$$

I now divide both sides by 2 to get

$$\tfrac{1}{2} m_1 v_{1i}^2 + \tfrac{1}{2} m_2 v_{2i}^2 = \tfrac{1}{2} m_1 v_{1f}^2 + \tfrac{1}{2} m_2 v_{2f}^2. \quad (5.11)$$

As you saw in Section 5.2, the quantity $\frac{1}{2}mv^2$ is the **kinetic energy**, which we denote by K:*

$$K \equiv \tfrac{1}{2} m v^2. \quad (5.12)$$

With this definition, Eq. 5.11 simplifies to

$$K_{1i} + K_{2i} = K_{1f} + K_{2f} \quad (\text{elastic collision}), \quad (5.13)$$

where $K_{1i} = \frac{1}{2} m_1 v_{1i}^2$ is the initial kinetic energy of object 1, and so on. In words, in an elastic collision the sum of the initial kinetic energies is the same as the sum of the final kinetic energies.

*The factor $\frac{1}{2}$ in Eq. 5.12 is there for convenience. We could have defined kinetic energy as simply mv^2, but the definition given in Eq. 5.12 simplifies matters later on.

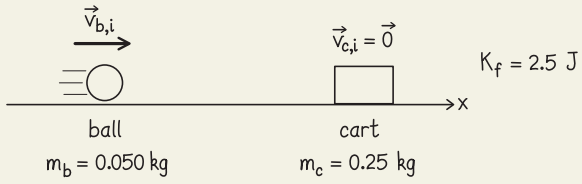
Note that there is no new physics in Eqs. 5.11 and 5.13—both express the same fact as Eq. 5.3. The great advantage of writing this information in the form of Eq. 5.13 is that this form expresses Eq. 5.3 in terms of an extensive quantity. Because kinetic energy is an extensive quantity, the kinetic energy of a system comprising two objects is the sum of the kinetic energies of the individual objects: $K = K_1 + K_2$. Equation 5.13 thus tells us that the kinetic energy K of a system of objects undergoing an elastic collision does not change:

$$K_i = K_f \quad (\text{elastic collision}). \tag{5.14}$$

This result can also be written in the form

$$\Delta K = 0 \quad (\text{elastic collision}). \tag{5.15}$$

As you know from studying Table 5.1, the SI unit for kinetic energy is $\text{kg}\cdot\text{m}^2/s^2$. Because energy is such an important quantity, we give this combination of units the name **joule** (rhymes with *pool*), after the British physicist James Prescott Joule (1818–1889), who studied energy:



$$1\ \text{kg}\cdot\text{m}^2/\text{s}^2 \equiv 1\ \text{J}.$$

EXAMPLE 5.6 Collision and kinetic energy

A rubber ball of inertia $m_b = 0.050$ kg is fired along a track toward a stationary cart of inertia $m_c = 0.25$ kg. The kinetic energy of the system after the two collide elastically is 2.5 J. (*a*) What is the initial velocity of the ball? (*b*) What are the final velocities of the ball and the cart?

❶ **GETTING STARTED** I organize the problem graphically (**Figure 5.17**). I choose my x axis in the direction of the incoming rubber ball. Only one initial velocity is given. I need to determine the other initial velocity and both final velocities.

Figure 5.17

❷ **DEVISE PLAN** Because the collision is elastic, I know that the kinetic energy of the system doesn't change, which means that the final value (2.5 J) is the same as the initial value. Because the cart is initially at rest, all of this kinetic energy belongs initially to the ball, and so I can use Eq. 5.12 to determine the initial velocity of the ball. Once I have this information, I know the initial velocities of both colliding objects and I can use Eqs. 1 and 2 from Example 5.5 to calculate the final velocities.

❸ **EXECUTE PLAN** (*a*) From Eq. 5.12, I obtain the initial speed of the ball:

$$v_{b,i} = \sqrt{\frac{2K_{b,i}}{m_b}} = \sqrt{\frac{2(2.5\ \text{J})}{0.05\ \text{kg}}} = 10\ \text{m/s}.$$

Because the ball is initially moving in the positive x direction, its initial velocity is given by $v_{bx,i} = +10$ m/s. ✔

(*b*) I can now substitute the two initial velocities and the inertias into Eqs. 1 and 2 of Example 5.5, which gives me $v_{bx,f} = -6.7$ m/s and $v_{cx,f} = +3.3$ m/s. ✔

❹ **EVALUATE RESULT** It makes sense that the velocity of the ball is reversed by the collision because the inertia of the cart is so much greater than that of the ball. Now that I know both the initial and final velocities, I can also check to make sure that the relative speed remains the same. Because the cart is initially at rest, the initial relative speed is 10 m/s; the final relative speed is $v_{bc,f} = |(+3.3\ \text{m/s}) - (-6.7\ \text{m/s})| = 10$ m/s, which is the same, as required for an elastic collision.

5.10 Conservation of momentum tells us that mv_x doesn't change for an isolated system. Now we see that in an elastic collision mv_x^2 also doesn't change. Does this mean that mv_x^3 remains unchanged, too?

QUANTITATIVE TOOLS

5.6 Inelastic collisions

In a totally inelastic collision between two objects, the objects move together after the collision and so the two final velocities are identical. This means that the final relative speed is zero:

$$v_{12f} = 0 \quad (\text{totally inelastic collision}). \tag{5.16}$$

Therefore if you know the inertias m_1 and m_2 of the objects and the x components of their initial velocities $v_{1x,i}$ and $v_{2x,i}$, you can obtain the final velocities from Eq. 5.5 by setting

$$v_{1x,f} = v_{2x,f} \quad (\text{totally inelastic collision}). \tag{5.17}$$

The majority of collisions, however, fall somewhere between the two extremes of elastic and totally inelastic. For these collisions, the final relative speed is between zero and the value of the initial relative speed. For these cases, it is convenient to define the ratio of relative speeds as

$$e \equiv \frac{v_{12f}}{v_{12i}}. \tag{5.18}$$

The unitless quantity e is called the **coefficient of restitution** of the collision. It tells us how much of the initial relative speed is restituted (restored) after the collision. Because it is a ratio of speeds (which are always positive), e is always positive or zero.

In general, it is more convenient to write Eq. 5.18 in terms of components:

$$e = -\frac{v_{2x,f} - v_{1x,f}}{v_{2x,i} - v_{1x,i}} = -\frac{v_{12x,f}}{v_{12x,i}}, \tag{5.19}$$

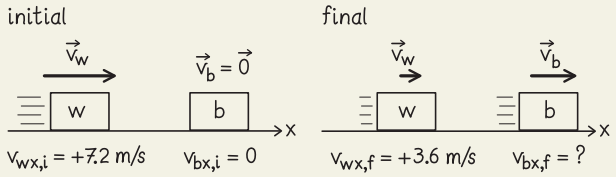
where the minus sign appears because the relative velocity changes sign after the collision (see Figure 5.15).

When $e = 1$, Eq. 5.19 is equal to Eq. 5.4 and the collision is elastic (all of the initial relative speed is restored). A value of $e = 0$ means that v_{12f} must be zero, and so the collision is totally inelastic. For values of e between 0 and 1, the collision is inelastic. This information is summarized in Table 5.4.

In an inelastic collision, therefore, we again have two equations—Eqs. 5.1 and 5.19—but we need to know the value of e to be able to calculate the final velocities. The details of how the states of the objects change in the collision (these state changes depend on the material and structural properties of the objects) are hidden in this coefficient e.

Table 5.4 Coefficient of restitution for various processes

Process	Relative speed	Coefficient of restitution
totally inelastic collision	$v_{12f} = 0$	$e = 0$
inelastic collision	$0 < v_{12f} < v_{12i}$	$0 < e < 1$
elastic collision	$v_{12f} = v_{12i}$	$e = 1$
explosive separation*	$v_{12f} > v_{12i}$	$e > 1$



*See Section 5.8.

EXAMPLE 5.7 Restitution

A white car of inertia 1200 kg that is moving at a speed of 7.2 m/s rear-ends a blue car of inertia 1000 kg that is initially at rest. Immediately after the collision, the white car has a speed of 3.6 m/s. What is the coefficient of restitution for this collision?

❶ **GETTING STARTED** By putting all the information in graphical form (**Figure 5.18**), I see that I do not have a value for the final velocity of the blue car, which I need in order to calculate the coefficient of restitution.

Figure 5.18

❷ **DEVISE PLAN** Because the system of the two colliding cars is isolated, I can use conservation of momentum (Eq. 5.5) to obtain the final velocity of the blue car, $v_{bx,f}$.

❸ **EXECUTE PLAN** I begin by writing Eq. 5.5 with subscripts appropriate to this particular collision:

$$m_w v_{wx,i} + m_b v_{bx,i} = m_w v_{wx,f} + m_b v_{bx,f}$$

or $$m_w v_{wx,i} + 0 = m_w v_{wx,f} + m_b v_{bx,f}.$$

Solving for $v_{bx,f}$ and substituting the values given, I get

$$v_{bx,f} = \frac{m_w}{m_b}(v_{wx,i} - v_{wx,f})$$

$$= \frac{1200\text{ kg}}{1000\text{ kg}}(7.2\text{ m/s} - 3.6\text{ m/s}) = 4.3\text{ m/s}.$$

Now I can substitute the initial and final velocities into Eq. 5.19 to obtain the coefficient of restitution:

$$e = -\frac{v_{wx,f} - v_{bx,f}}{v_{wx,i} - v_{bx,i}}$$

$$= -\frac{(+3.6\text{ m/s}) - (+4.3\text{ m/s})}{(7.2\text{ m/s}) - 0} = 0.097. \checkmark$$

❹ **EVALUATE RESULT** The coefficient of restitution is rather small, but that is to be expected because cars don't bounce like superballs. Indeed, the blue car moves just a little bit faster than the white car after the collision (4.3 m/s versus 3.6 m/s), as I expect.

5.11 In a totally inelastic collision between two objects in an isolated system with one of the objects initially at rest, is it possible to lose *all* of the system's initial kinetic energy?

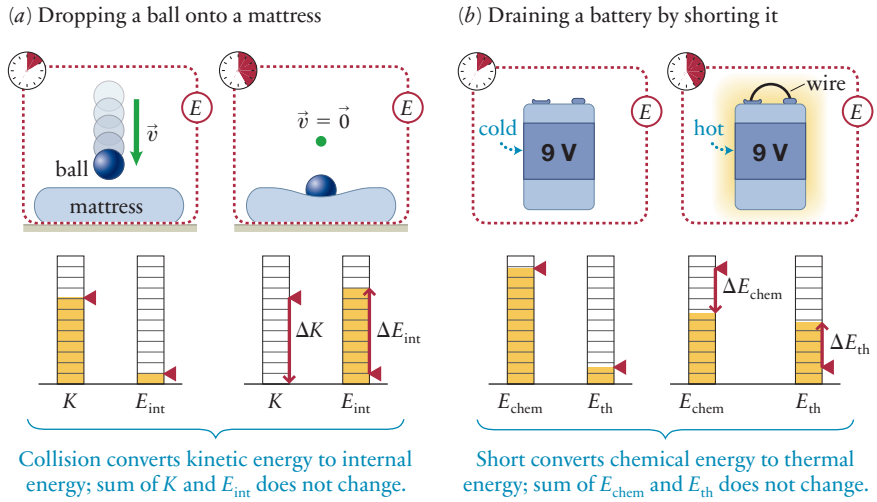
5.7 Conservation of energy

Because no energy is transferred to or from a closed system, conservation of energy requires that any change in the kinetic energy of a closed system be compensated by an equal change in the internal energy so that the sum of the kinetic and internal energies of the system does not change:

$$K_i + E_{int,i} = K_f + E_{int,f} \quad \text{(closed system)}. \tag{5.20}$$

In contrast to Eq. 5.14, which holds for only an elastic collision, Eq. 5.20 holds for any closed system. If we write the sum of the kinetic and internal energies of an object or system as the **energy** of the object or system,

$$E \equiv K + E_{int}, \tag{5.21}$$



then we can rewrite Eq. 5.20 as

$$zE_i = E_f \quad \text{(closed system)} \tag{5.22}$$

or $$\Delta E = 0 \quad \text{(closed system)}. \tag{5.23}$$

Note the parallel between Eq. 4.17, $\Delta\vec{p} = \vec{0}$, and Eq. 5.23. Equation 4.17 embodies conservation of momentum and states that the momentum of an isolated system cannot change. Equation 5.23 embodies conservation

Figure 5.19 Two examples of energy conservation in a closed system. (*a*) The ball's kinetic energy is converted to internal energy in the deformed mattress. (*b*) Chemical energy stored in the battery is converted to thermal energy (the battery gets hot). In both cases, as the bar graphs show, the system's energy remains the same.

of energy: It states that the energy of a closed system cannot change; that is, energy cannot be created or destroyed.

Even though we cannot yet calculate the internal energy E_{int}, Eq. 5.23 allows us to draw a number of important conclusions. First, if the kinetic energy of a closed system changes, then the state of the system must change in such a way that its internal energy changes by an amount

$$\Delta E_{\text{int}} = -\Delta K \quad \text{(closed system)}. \tag{5.24}$$

As an example, consider **Figure 5.19*a***. A ball is dropped onto a mattress, where it comes to rest. During the time interval from the instant just before the ball hits the mattress to the instant at which the ball comes to rest, the motion of the ball changes and the shape of the mattress changes. The ball and mattress constitute a closed system, and so the decrease in kinetic energy must be accompanied by an increase in internal energy. Equation 5.24 requires the loss in kinetic energy to be equal to the gain in internal energy.

The second conclusion we can draw from Eq. 5.23 is that if the kinetic energy of a closed system does not change ($\Delta K = 0$), neither does the internal energy of the system ($\Delta E_{\text{int}} = 0$). Because E_{int} is the sum of the internal energies of all the parts that make up the system, however, $\Delta E_{\text{int}} = 0$ does *not* mean that no changes in state take place. For instance, E_{int} remains constant when internal energy is transferred from one part of a closed system to another:

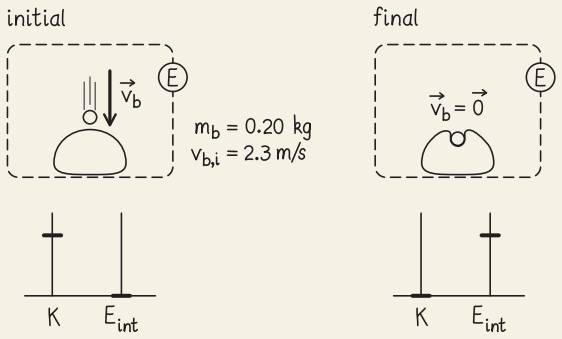
$$\Delta E_{\text{int},1} = -\Delta E_{\text{int},2} \Rightarrow \Delta E_{\text{int}} = 0 \quad \text{(closed system, } \Delta K = 0\text{)} \tag{5.25}$$

or when one form of internal energy is converted to another:

$$\Delta E_{\text{form 1}} = -\Delta E_{\text{form2}} \Rightarrow \Delta E_{\text{int}} = 0 \quad \text{(closed system, } \Delta K = 0\text{)}. \tag{5.26}$$

As an example, consider Figure 5.19*b*. When the battery is drained rapidly, it becomes very hot (as does the wire). Because there is no motion before and after the draining, no change in kinetic energy occurs, but the chemical energy in the battery is converted to thermal energy. Equation 5.26 requires the loss in chemical energy to be equal to the gain in thermal energy:

$$\Delta E_{\text{chem}} + \Delta E_{\text{th}} = 0. \tag{5.27}$$



In practice there are often more than two simultaneous changes of state in a system (see Checkpoint 5.8, for instance), but regardless of how many energy conversions and transfers take place, the law of conservation of energy requires that the *amount of energy* in a closed system never changes.

EXAMPLE 5.8 Making light

A 0.20-kg steel ball is dropped into a ball of dough, striking the dough at a speed of 2.3 m/s and coming to rest inside the dough. If it were possible to turn all of the energy converted in this totally inelastic collision into light, how long could you light a desk lamp? It takes 25 J to light a desk lamp for 1.0 s.

❶ **GETTING STARTED** I begin by applying the procedure for choosing a closed system. Although the problem doesn't specify it explicitly, I'm assuming the dough is at rest both before and after the steel ball is dropped in it; it could, for example, be at rest on a countertop. Only the steel ball has kinetic energy initially, and all of this energy is converted to internal energy as the ball comes to rest in the dough (Figure 5.20). So I have to calculate the initial kinetic energy of the ball and determine how long that amount of energy could light a lamp, given that 25 J lights a lamp for 1.0 s.

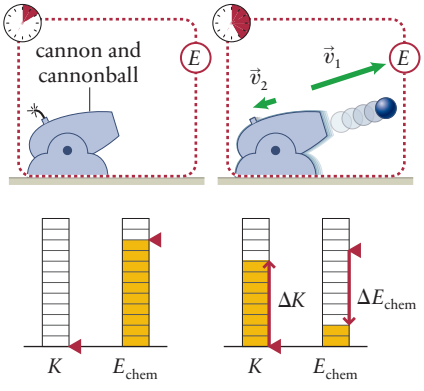
Figure 5.20

❷ **DEVISE PLAN** To determine the initial kinetic energy of the ball, I use Eq. 5.12. Then I divide this result by 25 J to determine how many seconds I can light a lamp.

❸ **EXECUTE PLAN** The initial kinetic energy of the ball is

$$K_{b,i} = \tfrac{1}{2} m_b v_{b,i}^2 = \tfrac{1}{2}(0.20\text{ kg})(2.3\text{ m/s})^2 = 0.53\text{ J}.$$

Given that a desk lamp requires 25 J per second, this 0.53 J lights a lamp for



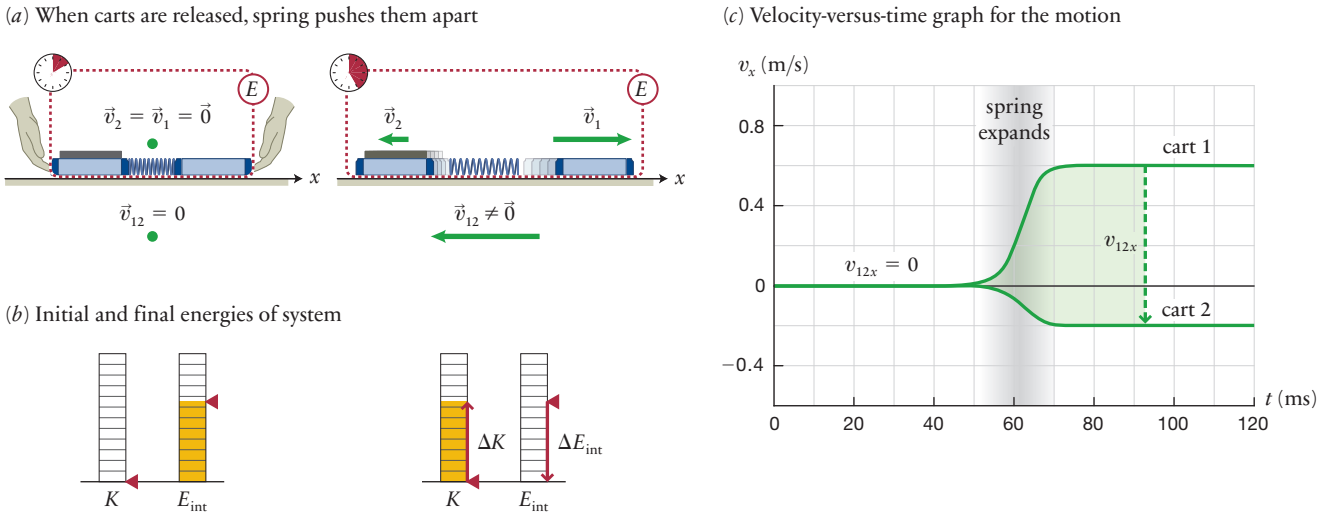
$$\frac{\text{energy available}}{\text{energy needed per second}} = \frac{0.53\text{ J}}{25\text{ J/s}} = 0.021\text{ s}. \checkmark$$

❹ **EVALUATE RESULT** The length of time I obtained, two hundreths of a second, is not very much! However, a 0.20-kg steel ball moving at 2.3 m/s does not have much kinetic energy: I know from experience that a small steel ball's ability to induce state changes—to crumple or deform objects, for example—is very limited. So it makes sense that one can't light a desk lamp for very long.

5.12 A gallon of gasoline contains approximately 1.2×10^8 J of energy. If all of this energy were converted to kinetic energy in a 1200-kg car, how fast would the car go?

5.8 Explosive separations

Figure 5.21 When a cannon is fired, internal (chemical) energy is converted to kinetic energy.



Is it possible to have a process in which kinetic energy is *gained* at the expense of internal energy? Yes, in an *explosion*, or any other type of **explosive separation**, where objects separate or break apart from each other, kinetic energy increases and internal energy decreases. The firing of a cannon is one example (Figure 5.21). Initially the cannon and cannonball are at rest. When the cannon is fired, the cannonball flies out of the barrel, and the cannon *recoils* in the opposite direction. (If it didn't recoil, the momentum of the system would not remain zero.) Both the cannon and cannonball therefore gain kinetic energy at the expense of chemical energy in the gun powder. This situation is the inverse of a totally inelastic collision: In this explosive separation, we start with the two objects together ($v_{12} = 0$) and end with them moving apart ($v_{12} > 0$).

Figure 5.22*a* shows an explosive separation that can be carried out on a low-friction track. Two carts, of inertias m and $3m$, are held against a compressed spring. When the carts are released, they move apart as the

QUANTITATIVE TOOLS

Figure 5.22 Another example of an explosive separation.

spring expands. As it expands, the spring's state changes and so does its internal energy; the decrease in internal energy of the spring causes an increase in the kinetic energy of the carts (Figure 5.22*b*). Notice how the velocity-versus-time graph for this explosive separation (Figure 5.22*c*) is the inverse of the one in Figure 5.2*b*.

To determine the final speeds in Figure 5.22, we need to know how much energy E_{int} the spring releases, a topic not covered until Chapter 9. Once we know ΔE_{int}, we have two equations that allow us to obtain the two final velocities, one a consequence of conservation of momentum:

$$0 = m_1 v_{1x,f} + m_2 v_{2x,f} \tag{5.28}$$

(because $v_{1x,i} = v_{2x,i} = 0$) and the other a consequence of conservation of energy:

$$\Delta K + \Delta E_{int} = \tfrac{1}{2} m_1 v_{1f}^2 + \tfrac{1}{2} m_2 v_{2f}^2 + \Delta E_{int} = 0. \tag{5.29}$$

Note that in this example the *initial* relative speed is zero, making e in Eq. 5.19 infinite. There is no restitution because there is no initial relative speed to be restituted. In the more general case where the two objects have a nonzero initial relative speed, $e > 1$.

EXAMPLE 5.9 Spring energy

A 0.25-kg cart is held at rest against a compressed spring as in Figure 5.8*a* and then released. The cart's speed after it separates from the spring is 2.5 m/s. The spring is then compressed by the same amount between a 0.25-kg cart and a 0.50-kg cart, as shown in Figure 5.22*a*, and the carts are released from rest. What are the carts' speeds after separating from the spring?

❶ **GETTING STARTED** The key point in this problem is the identical compression of the spring in the two cases: The initial state of the spring is therefore the same before both releases. Because the spring ends in the same uncompressed state in both cases, the change in its internal energy must be the same in both cases. In the first case, all of this energy is transferred to the 0.25-kg cart. In the second case, the same amount of energy is distributed between the two carts.

❷ **DEVISE PLAN** To calculate the kinetic energy of the single cart in the first release, I use Eq. 5.12. This gives me the amount of energy stored in the compressed spring. The final velocities of the two carts in the second case are then given by Eqs. 5.28 and 5.29.

❸ **EXECUTE PLAN** From Eq. 5.12, I get

$$K = \tfrac{1}{2} m v^2 = \tfrac{1}{2} (0.25\ \text{kg}) (2.5\ \text{m/s})^2 = 0.78\ \text{J}$$

and so the change in the spring's internal energy is $\Delta E_{int} = -0.78$ J. Next I rewrite Eq. 5.28 as $v_{1x,f} = -(m_2/m_1) v_{2x,f}$. Substituting this result in Eq. 5.29, I get

$$\tfrac{1}{2} m_1 \left(\frac{m_2}{m_1} \right)^2 v_{2x,f}^2 + \tfrac{1}{2} m_2 v_{2x,f}^2 = -\Delta E_{int}.$$

(Continued)

QUANTITATIVE TOOLS

Solving for the final velocity of cart 2 gives

$$v_{2xf} = \sqrt{\frac{-2m_1\Delta E_{int}}{m_2(m_1 + m_2)}}$$

$$v_{2xf} = \sqrt{\frac{-2(0.25\text{ kg})(-0.78\text{ J})}{(0.50\text{ kg})(0.25\text{ kg} + 0.50\text{ kg})}} = 1.0\text{ m/s.}\ \checkmark$$

Substituting this result into my rewritten Eq. 5.28, $v_{1x,f} = -(m_2/m_1)v_{2x,f}$, I get $v_{1x,f} = -2.0$ m/s. ✔

4 EVALUATE RESULT The carts move in opposite directions, as expected. I also note that cart 1 moves at twice the speed of cart 2, as it should to keep the final momentum of the system zero. Finally, because my assignment of m_1 and m_2 is arbitrary, I verify that I get the same result when I substitute $m_1 = 0.50$ kg and $m_2 = 0.25$ kg. (You may want to check this yourself. When you reverse the inertias, why does the velocity of cart 1 reverse to positive and the velocity of cart 2 reverse to negative?)

5.13 Does each cart in Example 5.9 get half of the spring's energy? Why or why not?

Chapter Summary

Kinetic energy (Sections 5.2, 5.5)

Concepts The **kinetic energy** of an object is the energy associated with its motion. Kinetic energy is a positive scalar quantity and is independent of the direction of motion.

Quantitative Tools The **kinetic energy** K of an object of inertia m moving at speed v is

$$K = \tfrac{1}{2}mv^2. \tag{5.12}$$

The SI unit of kinetic energy is the **joule** (J):

$$1\ \text{J} = 1\ \text{kg}\cdot\text{m}^2/\text{s}^2.$$

Relative velocity, states, and internal energy (Sections 5.1, 5.3, 5.5)

Concepts In a collision between two objects, the velocity of one object relative to the velocity of the other object is the **relative velocity** $\vec{v}_{12}$. The magnitude of the relative velocity is the **relative speed** v_{12}.

The **state** of an object is its condition as specified by some complete set of physical parameters. Energy associated with the object's state but not with its motion is called the **internal energy** of the object.

We can consider a system of two colliding objects to be isolated during the collision. Therefore the momentum of the system remains constant during all the collisions we study.

Quantitative Tools The **relative velocity** $\vec{v}_{12}$ of object 2 relative to object 1 is

$$\vec{v}_{12} \equiv \vec{v}_2 - \vec{v}_1. \tag{5.1}$$

The **relative speed** v_{12} of object 2 relative to object 1 is the magnitude of $\vec{v}_{12}$:

$$v_{12} = |\vec{v}_2 - \vec{v}_1|.$$

Because momentum is a conserved quantity, the momentum of a system remains constant during a collision:

$$p_{x,\text{i}} = p_{x,\text{f}}.$$

Types of collisions (Sections 5.5, 5.6, 5.8)

Concepts The **coefficient of restitution** e for a collision is a positive, unitless quantity that tells how much of the initial relative speed is restored after the collision.

For an **elastic collision,** the relative speed is the same before and after the collision, and the coefficient of restitution is equal to 1. The collision is **reversible,** and the kinetic energy of the system made up of the colliding objects is constant.

For an **inelastic collision,** the relative speed after the collision is less than it was before the collision. The coefficient of restitution is between 0 and 1, and the collision is **irreversible.** The kinetic energy of the objects changes during the collision, but the energy of the system does not change. If the objects stick together, the final relative speed is zero; the collision is **totally inelastic,** and the coefficient of restitution is 0.

Quantitative Tools The **coefficient of restitution** e is

$$e = \frac{v_{12\text{f}}}{v_{12\text{i}}} = -\frac{v_{2x,\text{f}} - v_{1x,\text{f}}}{v_{2x,\text{i}} - v_{1x,\text{i}}}. \tag{5.18, 5.19}$$

For an **elastic collision,**

$$v_{12\text{i}} = v_{12\text{f}} \tag{5.3}$$

$$K_\text{i} = K_\text{f} \tag{5.14}$$

$$e = 1.$$

For an **inelastic collision,**

$$v_{12\text{f}} < v_{12\text{i}}$$

$$K_\text{f} < K_\text{i}$$

$$0 < e < 1.$$

For a **totally inelastic collision,**

$$v_{12\text{f}} = 0 \tag{5.16}$$

$$e = 0.$$

For an **explosive separation,** kinetic energy is gained during the collision and the coefficient of restitution is greater than 1.

For an **explosive separation,**

$$v_{12f} > v_{12i}$$
$$K_f > K_i$$
$$e > 1.$$

Conservation of energy (Sections 5.3, 5.4, 5.7)

Concepts The energy of any system is the sum of the kinetic energies and internal energies of all the objects that make up the system.

The law of **conservation of energy** states that energy can be transferred from one object to another or converted from one form to another, but it cannot be destroyed or created.

A **closed system** is one in which no energy is transferred in or out. The energy of such a system remains constant.

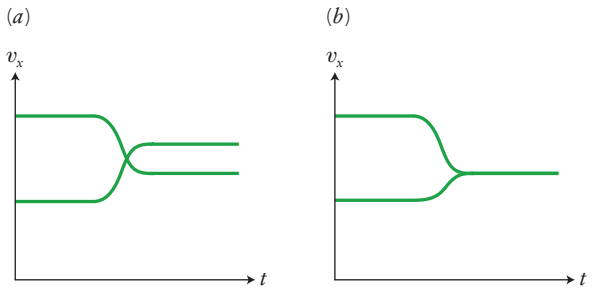
Quantitative Tools The energy of a system is

$$E = K + E_{int}. \tag{5.21}$$

The law of conservation of energy requires the energy of a **closed system** to be constant:

$$E_i = E_f. \tag{5.22}$$

Questions and Problems



For instructor-assigned homework, go to Mastering Physics

Dots indicate difficulty level of problems: • = *easy,* •• = *intermediate,* ••• = *hard;* CR = *context-rich problem.*

5.1 Classification of collisions

1. In a billiard game, two balls collide having inertia 0.25 kg each. Initially, ball 1 with velocity 8 m/s hits the ball 2 at rest. After collision, ball 1 moves with velocity 5 m/s and ball 2 moves with velocity 3 m/s. Comment whether the collision is elastic or inelastic. •
2. Suppose you have an isolated system in which two objects about to collide have equal and opposite momenta. If the collision is totally inelastic, what can you say about the motion after the collision? •
3. Figure P5.3 shows velocity-versus-time graphs for two situations in which a pair of objects collide. For each situation, decide whether the collision is elastic, inelastic, or totally inelastic. ••

Figure P5.3

4. When you drop a tennis ball on the floor from a height, it will bounce back. (*a*) Do you expect the ball to return to the same height? (*b*) Is this collision elastic or inelastic? Justify your answer. ••

5.2 Kinetic energy

5. The ratio of kinetic energies of two moving objects A and B is 1:5. Calculate the ratio of their momenta if the inertia of A is 5 times the inertia of B. •
6. As a result of an elastic collision between carts 1 and 2, the kinetic energy of cart 1 doubles. Does the kinetic energy of cart 2 change? If so, by what amount? •
7. A common energy unit used in food chemistry is the *food calorie* (1 Cal = 1000 cal = 4186 J). What must be the inertia of a person who is moving at a walking pace of 1.0 m/s and has kinetic energy numerically equal to the food energy in a jelly doughnut (300 Cal)? •
8. (*a*) Write an expression for the kinetic energy of an object in terms of its momentum p and inertia m. (*b*) If kinetic energy can be written in terms of momentum, how can the kinetic energy of a system change in an inelastic collision even though the law of momentum conservation forces the system's momentum to remain unchanged? ••
9. If two objects A and B have the same momentum but A has four times the kinetic energy of B, what is the ratio of their inertias? ••
10. The ratio of momenta of two objects A and B is 1: 4. The ratio of the kinetic energies of A and B is 1:2. Find the ratio of their velocities. ••
11. Object X has great inertia, and object Y has much less inertia. If the objects have the same momentum, which has more kinetic energy? If they have the same kinetic energy, which has greater momentum? ••

12. Draw a graph of kinetic energy versus distance fallen for a brick that is falling vertically from the top of a tall building. ••

5.3 Internal energy

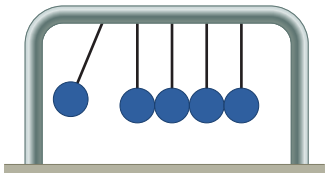
13. You see a book on a table and give the book a push. It slides across the table and then comes to rest. Describe any changes in the physical state of the book-table system. •
14. What is the interaction type in each of the following cases: (*a*) two colliding marbles, (*b*) two cars in a collision in which they move together, (*c*) a bullet fired into and passing through a wooden block, (*d*) a bullet fired into a wooden block that gets embedded in it, and (*e*) one cart hitting another on a low-friction air track. •
15. What physical phenomenon is at work in the launching of a rocket? Is the performance of the rocket engine better on earth or in space? •
16. A small bullet is fired into a large piece of wood. After the bullet penetrates the wood, the assembly moves as one unit along a low-friction track in the direction of travel of the bullet. (*a*) After the bullet is stuck in the piece of wood, is the momentum of the wood (not including the bullet) *greater than, equal to,* or *less than* the initial momentum of the bullet? State any assumptions explicitly. (*b*) Is the combined kinetic energy of the bullet and the wood after the bullet is stuck in the wood *greater than, equal to,* or *less than* the initial kinetic energy of the bullet? ••
17. A block slides with speed v across a low-friction, horizontal surface and collides with and sticks to an identical block at rest. The combination then strikes a spring attached to a fixed wall, bouncing off elastically. (*a*) Choose a system and discuss whether it is isolated. (*b*) Sketch energy bar diagrams for the initial state, the state after the first collision, the state during the collision with the spring, and the state after the final collision. (*c*) Discuss which types of internal energy are involved during this entire sequence of events. (*d*) Determine the final speed of the combined blocks. ••

5.4 Closed systems

18. Light a matchstick by striking at the edge of the match box. If the event takes place in a room that can be considered a closed system, what are the consequences? If the same event occurs inside an isolated system, will there be any change? •
19. Why are most of the massive meteoroids not able to hit the Earth's surface? Explain your answer in terms of energy. •
20. Imagine making two springy devices, each made up of a dozen or so metal blocks loosely connected by springs, and then making the two collide head-on. Do you expect the collision to be elastic, inelastic, or totally inelastic? If the collision is not elastic, where does the kinetic energy go? ••
21. Car A is at rest when an identical car, B, rear-ends it and they move together. What fraction of the kinetic energy of car B is lost? ••
22. In the past, cars were built to be fairly rigid in collisions. Now "crumple zones" (areas designed to crumple or deform during a collision) are deliberately engineered. Why do such zones make a car safer in a collision? ••

5.5 Elastic collisions

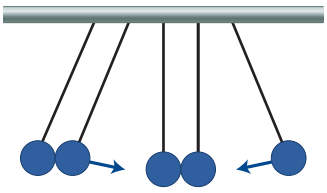
23. A ball of inertia m bounces elastically from the floor. It has x component of velocity $+v$ just before it hits the floor. What is the magnitude of its change in momentum in the collision? What is the change in its kinetic energy? Are your two answers consistent with each other? •
24. A 1200-kg car initially at rest undergoes constant acceleration for 8.8 s, reaching a speed of 10 m/s. It then collides with a stationary car that has a perfectly elastic spring bumper. What is the final kinetic energy of the two-car system? •
25. An elastic collision takes place between a 0.080-kg toy car moving at 10×10^2 m/h and a 0.016-kg toy car moving at 20×10^9 mm/yr. What is the kinetic energy of the system in joules? •
26. You want to give a third-grader a common example that illustrates how much energy a joule is. Show that a 0.1-kg ring of keys falling out of your pocket develops about 1 J of kinetic energy before hitting the ground. Can you think of another example? ••
27. You have an inertia of 52 kg and are standing at rest on an iced-over pond in your skates. Suddenly, your 60-kg brother skates in from the right with a speed of 5.0 m/s and collides elastically with you. (*a*) What is the siblings' relative speed after the collision? (*b*) If your brother's final velocity is 0.36 m/s toward the left, what is your final velocity? (*c*) Is your answer to part *b* consistent with your answer to part *a*? (*d*) What is the change in kinetic energy of the system of you and your brother? ••
28. Block A of inertia 2 kg moving at 5 m/s collides elastically with a stationary block, B, of unknown inertia. After the collision, A is moving in the same direction at 3 m/s. What is the inertia of block B? What is its velocity after the collision? ••
29. An object of inertia m_1 moving at v_{1i} collides elastically with an object of inertia m_2 initially at rest. Show that the following solution for the final velocities of the two objects after the collision conserves momentum and kinetic energy:



$$v_{1f} = \left(\frac{m_1 - m_2}{m_1 + m_2}\right) v_{1i}$$

$$v_{2f} = \left(\frac{2m_1}{m_1 + m_2}\right) v_{1i}$$ ••

30. Use the solutions in Problem 29 to explain the outcome of each of the following collisions:
    (*a*) A moving truck colliding with a bike initially at rest.
    (*b*) A bike colliding with a stationary truck.
    (*c*) A bike colliding with an identical stationary bike. ••



31. The device shown in Figure P5.31 is called a Newton's cradle. Any collision between the balls in the device in Figure P5.31 is elastic. (*a*) If one end ball is pulled back and let go, as shown, would it be a violation of conservation of momentum if two balls at the other end bounced up at half the first ball's speed? (*b*) Would the result in part *a* be a violation of conservation of energy? (*c*) Show that the *only* result consistent with both conservation laws is that for n balls raised and let go, n balls rise on the other side. ●●

Figure P5.31

32. Figure P5.32 shows a pattern for the balls in a Newton's cradle just before collision. The arrows indicate the directions of motion of the balls. All the balls have the same size and inertia, and they collide elastically. Assume that all the collisions happen at the same instant. Sketch the pattern of the balls immediately after the collision. ●●

Figure P5.32

33. A cart of inertia m_1 and velocity $\vec{v}_{1i}$ collides elastically with a cart of inertia m_2 initially moving at velocity $-0.5\vec{v}_{1i}$. What is the speed of each cart after the collision? ●●●
34. Two carts are initially moving to the right on a low-friction track, with cart 1 behind cart 2. Cart 1 has a speed twice that of cart 2 and so moves up and rear-ends cart 2, which has twice the inertia of cart 1. What is the speed of each cart right after the collision if the collision is elastic? ●●●

5.6 Inelastic collisions

35. A Labrador retriever dog with inertia 25 kg and velocity 6 m/s jumps into a trolley at rest and after that both move in the same direction with a velocity 3 m/s. Is the collision elastic, inelastic, or totally inelastic? Calculate the inertia of the trolley. ●
36. A physics student driving a 1200-kg car runs into the rear of a 2000-kg car stopped at a red light. From the fact that the joined vehicles skidded forward 4.0 m, the investigating police officer calculates that the speed after the collision was 6.6 m/s. Based on this information, calculate the student's speed before impact. ●
37. A basketball is thrown horizontally at a heavy door that is free to move. For the two cases in which the ball is (*a*) well inflated and (*b*) flat, sketch a system diagram of the ball and the door, showing momentum vectors and energy bars just before and just after the collision. Make your picture the view from above. ●
38. Draw a velocity-versus-time graph for a collision between a 2-kg object moving at an initial speed of 4 m/s and a 6-kg object initially at rest, if the coefficient of restitution is 0.25. ●●
39. Consider four identical cars. Two of them collide head-on when both are traveling at 34 m/s. The other two collide head-on when both are traveling at 25 m/s. What is the ratio of the amount of kinetic energy converted to internal energy in the two collisions? ●●
40. Take the common case where an object of inertia m_1 collides totally inelastically with a stationary object of inertia m_2. Show that the fraction of kinetic energy converted in the collision is $m_2/(m_1 + m_2)$. Comment on the amount of energy converted for the cases $m_2 \gg m_1$. and $m_2 \ll m_1$, ●●
41. Show that when a moving object collides with an identical stationary object, the ratio of the final and initial kinetic energies is related to the coefficient of restitution e by

$$\frac{K_f}{K_i} = \tfrac{1}{2}(1 + e^2).$$ ●●

42. A 2000-kg truck is sitting at rest (in neutral) when it is rear-ended by a 1000-kg car going 25 m/s. After the collision, the two vehicles stick together. (*a*) What is the final speed of the car-truck combination? (*b*) What is the kinetic energy of the two-vehicle system before the collision? (*c*) What is the kinetic energy of the system after the collision? (*d*) Based on the results of parts *b* and *c*, what can you conclude about which type of collision this is? (*e*) Calculate the coefficient of restitution for this collision. Is this the result you expect for *e*? ●●
43. Which head-on collision between a small car and a large truck causes a larger conversion of kinetic energy: one in which their initial momenta have the same magnitude, or one in which their initial kinetic energies are the same? Assume the same kinetic energy for the two-vehicle system in both cases. ●●●
44. You push a wooden block and friction causes it to stop eventually. If the acceleration during the process is constant, calculate the fraction of its kinetic energy lost as a function of the distance it was pushed through. Check your answer at the middle and end of its path. ●●●

5.7 Conservation of energy

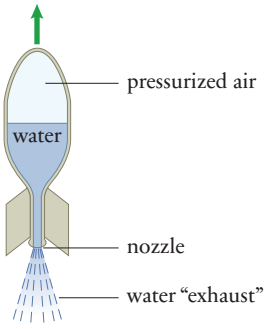
45. An experienced bartender knows just the right initial speed of a glass of beer to get it to come to a stop in front any customer sitting along the bar. Say the initial speed needed to move a glass all the way to the end of the bar is v_{end}. In terms of v_{end}, with what speed should an identical glass of beer be released if it is to stop at a customer sitting three-quarters of the way down the bar? (The kinetic energy converted to thermal energy because of friction is proportional to the distance the glass skids.) •
46. A car goes into a skid and gradually comes to a stop, accelerating at a constant rate. At the midpoint of the skid, how much of its kinetic energy has it lost? •
47. A 2-kg block moving at 4 m/s hits a slower 1-kg block moving at 2 m/s. If the 2-kg block continues in the same direction at 3 m/s, (*a*) what is the speed of the slower block? (*b*) Is the collision elastic? (*c*) By what factor does the internal energy of the system change? ••
48. A 1200-kg car is backing out of a parking space at 5.0 m/s. The unobservant driver of a 1800-kg pickup truck is coasting through the parking lot at a speed of 3.0 m/s and runs straight into the rear bumper of the car. (*a*) What is the change in internal energy of the two-vehicle system if the velocity of the pickup is 1.5 m/s backward after they collide? (*b*) What is the coefficient of restitution for this collision? ••
49. Explain how a police officer at the scene of a car crash can judge whether or not you were speeding when you rear-ended a stopped car, based solely on the length of the skid marks after the collision. Is the speed the officer estimates for your speed just before the collision faster than, equal to, or slower than your actual speed? ••
50. A wagon is coasting along a level sidewalk at 5.00 m/s. Its wheels have very good bearings. You are standing on a low wall, and you drop vertically into the wagon as it passes by. The wagon has an inertia of 100 kg, and your inertia is 50.0 kg. (*a*) Use conservation of momentum to determine the speed of the wagon after you are in it. (*b*) Use conservation of energy to determine that speed. (*c*) After comparing your answers in parts *a* and *b*, explain which method is correct. ••
51. The extinction of the dinosaurs is, by one theory, attributed to a collision between Earth and an asteroid about 10 km in diameter moving at 25 km/s relative to Earth. Assume that the asteroid had about the same density as Earth. Estimate the energy released by such an impact in megatons of TNT, where 1 megaton $= 4.2 \times 10^{15}$ J. •••

5.8 Explosive separations

52. Can you tell from the coefficient of restitution whether a collision has added kinetic energy to a system, taken some away, or left the system's kinetic energy unchanged? •
53. If the video of an explosive separation (like the firing of a gun) is run backward, the event looks like a totally inelastic collision, with two or more originally separate pieces all sticking together. How are the coefficient of restitution for an explosive separation and that for a totally inelastic collision related to each other? •
54. At the peak of its vertical flight, a fireworks shell explodes into two pieces. Piece 1 has three times the speed of piece 2. What is the ratio of the inertias of the pieces? What is the ratio of their kinetic energies? ••
55. A 52-kg ice skater (this value includes her body, her clothing, and several 1.0-kg snowballs she is carrying) is at rest on the ice. She throws a snowball to the right at 10 m/s. (*a*) What is her speed after the throw? Is her velocity to the left or to the right? (*b*) Calculate the coefficient of restitution for this event. She next throws a second snowball but this time at a speed of 20 m/s to the left. (*c*) What is her speed after this throw? Is her velocity to the left or to the right? (*d*) Calculate the coefficient of restitution for this event. (*e*) Calculate the change in kinetic energy in this second event. Where does the added kinetic energy come from? (*f*) If one food calorie equals 4184 J, how many food calories does the skater burn when she throws the second snowball? ••
56. A mysterious crate has shown up at your place of work, Firecracker Company, and you are told to measure its inertia. It is too heavy to lift, but it rolls smoothly on casters. Getting an inspiration, you lightly tape a 0.60-kg iron block to the side of the crate, slide a firecracker between the crate and the block, and light the fuse. When the firecracker explodes, the block goes one way and the crate rolls the other way. You measure the crate's speed to be 0.055 m/s by timing how long it takes to cross floor tiles. You look up the specifications of the firecracker and find that it releases 9.0 J of energy. That's all you need, and you quickly calculate the inertia of the crate. What is that inertia? ••
57. A mysterious explosion in an unmanned 6000-kg spaceship coasting at 5000 m/s breaks the ship into two unequal parts, one twice as massive as the other. The smaller piece recoils in the direction opposite to the original path at 3000 m/s. (*a*) What is the velocity of the larger piece after the explosion? (*b*) Discuss the energy changes resulting from the explosion. ••
58. A system consists of a 4.0-kg cart and a 1.0-kg cart attached to each other by a compressed spring. Initially, the system is at rest on a low-friction track. When the spring is released, an explosive separation occurs at the expense of the internal energy of the compressed spring. If the change in the spring's internal energy during the separation is 1.0 kJ, what is the speed of each cart right after the separation? ••
59. A space shuttle of inertia m is attached to a booster rocket that has an inertia nine times greater. This system is moving at a speed of 800 m/s in outer space, as seen

by observers in a nearby space station. Then explosive bolts are detonated, separating the shuttle from the rocket and thrusting the shuttle forward at a speed of 100 m/s relative to the rocket. What are the velocities of the rocket and the shuttle right after the explosion? ••

60. A uranium-238 atom can break up into a thorium-234 atom and a particle called an *alpha particle*, α-4. The numbers indicate the inertias of the atoms and the alpha particle in *atomic mass units* ($1\text{ amu} = 1.66 \times 10^{-27}\text{ kg}$). When a uranium atom initially at rest breaks up, the thorium atom is observed to recoil with an x component of velocity of -2.5×10^5 m/s. How much of the uranium atom's internal energy is released in the breakup? ••



61. A stationary 5.0-kg ball explodes into two pieces due to a firecracker inside. One piece with inertia 2.0 kg travels to the left at 10 m/s. (*a*) What is the speed of the second fragment? (*b*) How much energy was released in the explosion? ••

62. An assembled system consists of cart A of inertia m_A, cart B of inertia m_B, and a spring of negligible inertia, clamped together so that the fully compressed spring is aligned between the front end of cart B and the back end of cart A. The internal energy of the system, stored in the compressed spring, is E_{spring}. The system is put on a low-friction track and given a small shove so that it moves to the right at speed v_i, with cart A in front. Once the system is moving, the clamp is released (by remote control, so that the motion of the system as a whole is not affected in any way). As the spring expands, the carts move apart. What are their final speeds? •••

63. Consider the same initial system of spring and carts A and B as in Problem 62. After the system is set in motion with common speed v_i, the clamp is again released. What is the speed of cart A at the instant when the spring is still partially compressed and stores one-fourth of its initial internal energy E_{spring}? •••

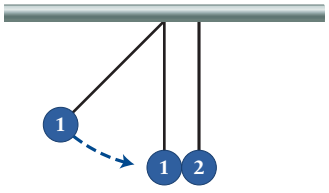
64. A toy water-rocket consists of an elongated plastic tank with a nozzle at one end (Figure P5.64). A hand pump is used to get pressurized air into the tank. If there is nothing but air in the tank, the performance is lackluster. If some water is put in the tank before it is pumped up with air, however, the flight is dramatically better. Why? •••

Figure P5.64

65. A fictional subatomic particle, the solarino, is initially at rest. It then explodes into three particles: two lightons and a heavyon. The inertia of a heavyon is twice the inertia of a lighton. In the explosive separation, the three particles can be kicked out in either direction along a straight line, but the internal energy of the solarino is always entirely converted to the kinetic energy of the three particles. (*a*) Draw the paths of the three particles for the case in which the heavyon has the greatest possible speed. (*b*) Draw the paths of the particles for the case in which one of the lightons has the greatest possible speed. •••

Additional Problems

66. Which has more kinetic energy: A 163-g cricket ball travelling at 150 km/h or a 58-g tennis ball travelling at 230 km/h? •



67. In javelin throw, an athlete usually runs a certain distance before the throw. Why does the athlete not throw their javelin from a stand-still position? •

68. You and a friend are playing catch with a medicine ball. The game has gotten a little unfriendly, and you'd like to knock your friend down with the next throw. To achieve this, should you suggest that your friend catch the ball with his hands or bounce it elastically back to you with his fists? ••

69. Your uncle works at the railroad freight yard, and he has asked you to watch the yard hands couple 20,000-kg boxcars together. As he leaves to get a sandwich, he tells you, "Whatever you do, don't let those cars bang together too hard. The couplings will take only 10,000 J on a hit before they shatter." You ask how hard is too hard, but your uncle has already ducked out. How fast can one moving car bump into a stationary (but free-to-move) car without the coupling shattering? ••• CR

70. Two solid spheres hung by thin threads from a horizontal support (Figure P5.70) are initially in contact with each other. Sphere 1 has inertia $m_1 = 0.050$ kg, and sphere 2 has inertia $m_2 = 0.10$ kg. When pulled to the left and released, sphere 1 collides elastically with sphere 2. At the instant just before the collision takes place, sphere 1 has kinetic energy $K_1 = 0.098$ J. (*a*) What is the velocity of sphere 1 right before the collision? (*b*) What is the kinetic energy of the system before the collision? (*c*) What is the velocity of each sphere after the collision? (*d*) From part *c*, calculate the kinetic energy after the collision. Does the value you get equal the result of part *b*? Explain why or why not. (*e*) Calculate the coefficient of restitution of the collision. Is this the result you expect? ••

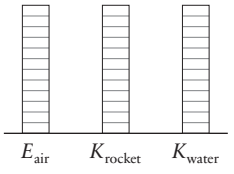


Figure P5.70

71. Repeat Problem 70 for two spheres made of modeling clay. All the data remain the same, but this time the two spheres stick together upon collision. ••

72. In the toy water-rocket of Problem 64, the pressurized air can store internal energy. Assume you have a rocket that expels water at a speed of 15.0 m/s and the opening through which the water leaves is 10.0 mm in diameter. (*a*) Using Figure P5.72 as a template, sketch energy bar graphs for three instants: when the rocket is fully pressurized but has not been launched, after the launch when half the water has been expelled, and after all the water has been expelled. (*b*) What is the approximate inertia of the water expelled in the first second of flight? (*c*) Does the rocket accelerate at a constant rate? ••

Figure P5.72

73. Suppose that, as it slides across the floor of a basketball arena, a hockey puck loses kinetic energy because of friction. The amount of energy lost is directly proportional to the distance the puck slides. Sketch a graph of kinetic energy versus time during this slide and then verify with a calculation. ●●●

74. While bowling one day, you begin to wonder about the inertia of a bowling pin. You know that balls and pins generally make elastic collisions and that your 6.5-kg bowling ball continues to move forward after a collision, even when you hit several pins to make a strike. As it happens, you have just managed to knock down nine of the ten pins, leaving only one pin upright at the end of the lane. You ask your friend to make a video of your next shot so that you can later carefully observe the initial and final velocities of your ball. Sure enough, you hit the remaining pin head-on (make the spare), and after a little video analysis you decide that your ball lost about 40% of its initial speed when it hit the pin. What is the inertia of that pin? ●●● CR

75. For a system of two identical cars, A and B, of the same inertia m but moving at two different velocities, v_A and v_B, show that the kinetic energy of the two-car system can be expressed as the sum of two terms: the kinetic energy of a double car moving with one-half the sum of their velocities, plus the kinetic energy of a double car moving with one-half the difference of their velocities:

$$K_{sum} = \tfrac{1}{2}(2m)\left[\frac{v_A + v_B}{2}\right]^2$$

$$K_{dif} = \tfrac{1}{2}(2m)\left[\frac{v_A - v_B}{2}\right]^2.$$

Interpret the meaning of each of these terms. ●●●

76. A 1000-kg car traveling with an x component of velocity of +20 m/s collides head-on with a 1500-kg light truck traveling with an x component of velocity of −10 m/s. (*a*) If 10% of the system's kinetic energy is converted to internal energy during the collision, what are the final speeds of the car and truck? (*b*) If the car had instead rear-ended the same truck moving with an x component of velocity of +10 m/s, how would your answer to part *a* change? ●●●

77. Your little brother is outside squirting a basketball with the stream of water from a garden hose. As the ball rolls across the yard, you begin to wonder what you would need to know in order to determine the rate at which momentum is transferred from the water to the ball. It should not be hard to measure both the radius r of the hose and the flow rate Q of water out of the hose in cubic meters per second. The density of water is certainly known, but you aren't sure whether the collision is elastic or inelastic. ●●● CR

78. Two hockey players push off from a clinch, recoiling from rest. Jean-Claude has an inertia that is 50% greater than Pierre's inertia. After they push off and move across the ice in opposite directions, they lose kinetic energy at the same rate until they come to a stop. (*a*) Who travels farther? (*b*) How much farther? ●●●

QUANTITATIVE TOOLS

6.5 Galilean relativity
6.6 Center of mass
6.7 Convertible kinetic energy
6.8 Conservation laws and relativity

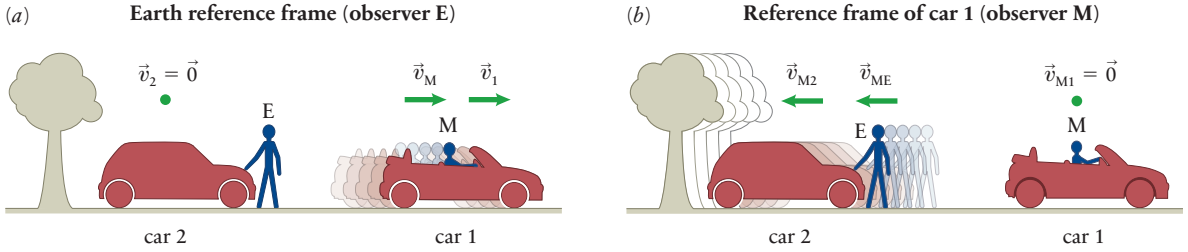
Did you ever, sitting in a car at a red light and looking at the car next to you, slam on the brakes because you thought you were starting to roll but it turned out your car never moved? If you did, you experienced the relativity of motion, first described quantitatively by Galileo. You may have heard the term *relativity* in the context of Albert Einstein's famous theories of general relativity and special relativity. We'll touch upon one basic aspect of general relativity in Chapter 13 and discuss special relativity in Chapter 14. Underlying all of relativity is something we have so far ignored in our discussion of motion: the fact that the velocity measured for any object depends on the **observer** (the person doing the measuring). For example, to a person sitting in a moving train, a suitcase on the overhead rack is at rest, but to a person standing on a station platform watching the train speed by, the suitcase is not at rest. According to the person in the train, the suitcase has zero momentum $(m\vec{v})$ and zero kinetic energy $\left(\frac{1}{2}mv^2\right)$. According to the person on the platform, the suitcase has nonzero momentum and nonzero kinetic energy. In this chapter we investigate whether or not the laws of conservation of momentum and conservation of energy depend on the velocity of the observer. In other words, if these laws are valid for one observer, are they also valid for an observer who is moving relative to the first observer?

6.1 Relativity of motion

Remember from Chapter 2 that whenever we talk about motion, we must specify a reference axis along which the motion occurs and an origin. Together, the axis and origin are called a **reference frame.** In our study of motion thus far, we have considered the motion of carts along a low-friction track, collecting our data using a ruler affixed to the track; that is to say, we collected our data while standing in a reference frame at rest relative to the surface of Earth (this is called an **Earth reference frame**).

What happens to the data if we are moving as we collect them—in other words, if we are in a reference frame that is moving relative to Earth? Imagine that we are moving alongside the track and want to describe a collision between two carts. Do the conservation laws hold in a reference frame that is moving relative to Earth? Or, to put the question another way, does the behavior of the carts change if we are in motion as we study that behavior?

Consider, for example, the situation depicted in **Figure 6.1*a***: two observers watching the motions of two cars. Car 1 is moving at constant velocity $\vec{v}_1$, and car 2 is at rest relative to Earth. Observer E is at rest relative to Earth, while observer M is inside car 1. The velocity $\vec{v}_M$ of observer M is the same as the velocity of car 1: $\vec{v}_M = \vec{v}_1$.



Relative to observer M, the position of car 1 is not changing; that is, car 1 is at rest relative to observer M. The distance to car 2, however, is steadily increasing, and so relative to observer M, car 2, observer E, and all the surroundings move to the left (Figure 6.1*b*). To distinguish quantities measured by different observers, we add a capital letter subscript to denote the observer. For instance, $\vec{v}_{M2}$ represents observer M's measurement of the velocity of car 2, also called the velocity of car 2 *relative to* observer M. When we are comparing quantities in various reference frames, quantities measured relative to Earth are given the subscript E. For example, relative to Earth the velocity of car 1 is represented by $\vec{v}_{E1}$ (When the Earth reference frame is the only reference frame, we drop the subscript E, recovering the notation we have used before: $\vec{v}_{E1} = \vec{v}_1$.)

To determine a relationship between the quantities measured by two observers moving relative to each other, let's start with a simple example. **Figure 6.2** on the next page shows five frames of a video of two carts on a low-friction track. In Figure 6.2*a* the positions of the two carts are measured with ruler A, which is affixed to the track (that is, in the Earth reference frame). Relative to ruler A, cart 1 is at rest and its left end remains fixed at 22.5 mm. Cart 2 is moving to the right, and the position of its right end on ruler A changes from 0 to 14.4 mm.

In Figure 6.2*b* the positions of the two carts are measured with ruler B, which moves along with cart 2: The zero mark on ruler B remains aligned with the front of cart 2. The position of cart 2 therefore remains fixed at

CONCEPTS

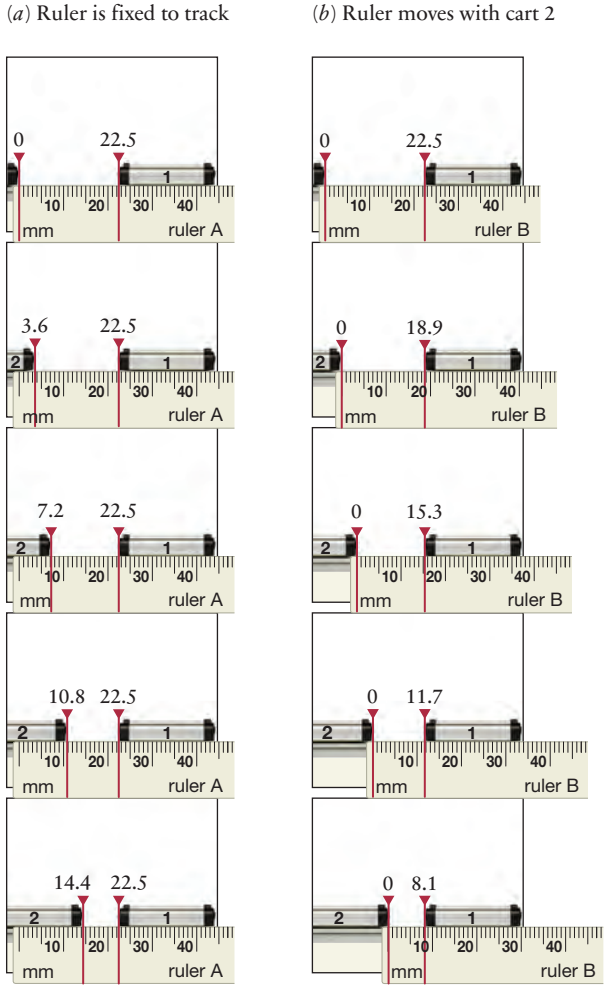


Figure 6.1 The motion you perceive depends on your reference frame.

Relative to observer E, car 2 is at rest and car 1 moves to the right.

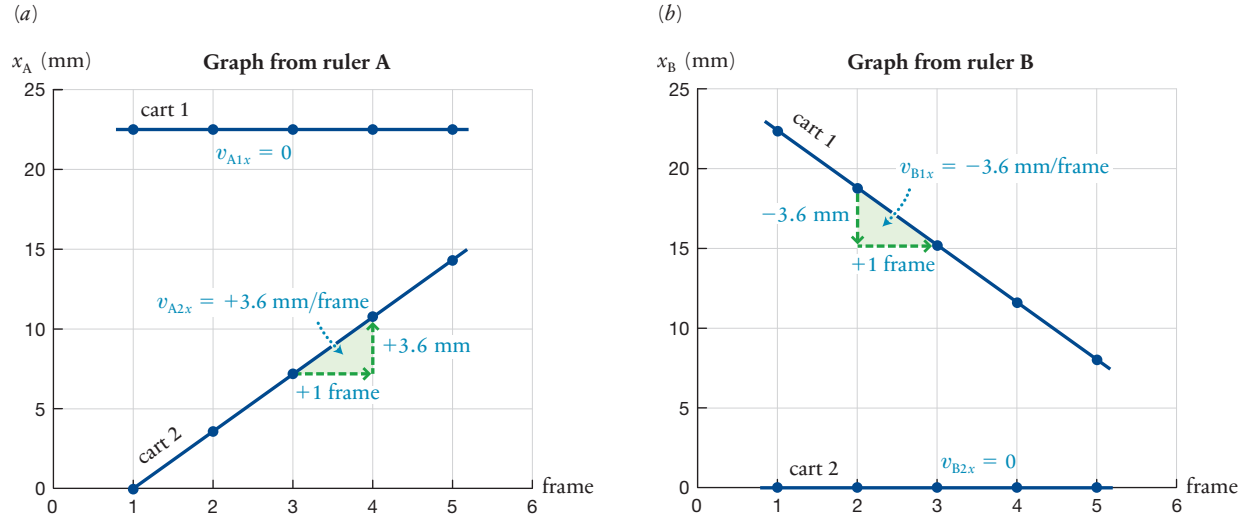
But relative to observer M, car 1 is at rest while car 2, observer E, and Earth move to the left.

Figure 6.2 Two identical carts on a low-friction track. The positions of the carts are measured with (*a*) a ruler affixed to the track and (*b*) a ruler moving along with cart 2. In the Earth reference frame, cart 1 is at rest and cart 2 is moving to the right.

a ruler reading of 0, and so, relative to ruler B, cart 2 is at rest. On this ruler, the position of cart 1 does *not* remain fixed, however—the reading for this cart's position decreases from 22.5 mm to 8.1 mm over the five frames. That is to say, cart 1 moves 22.5 mm − 8.1 mm = 14.4 mm *to the left* along ruler B.

Figure 6.3*a* shows a position-versus-frame graph for the two carts drawn from the readings on ruler A in Figure 6.2*a*. What is shown in the graph corresponds to what an observer at rest alongside the track sees: cart 1 at rest and the x component of the velocity of cart 2 a constant +3.6 mm/frame. These are the observations taken in the Earth reference frame.

Figure 6.3*b* is the position-versus-frame graph for the two carts drawn from the readings on ruler B in Figure 6.2*b*. What is shown in the graph corresponds to what an observer M sitting on top of cart 2 sees: cart 2 at rest and the x component of the velocity of cart 1 a constant −3.6 mm/frame (the negative sign indicates that the cart moves to the left in the figure).



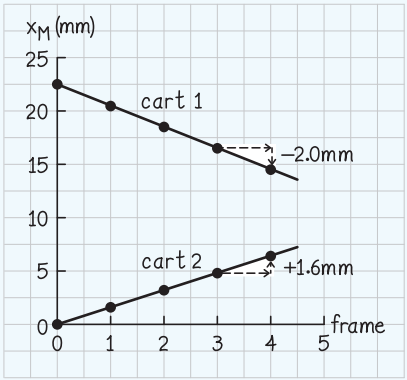
EXAMPLE 6.1 Moving at my own speed

Suppose that in the situation shown in Figure 6.2, a third ruler is affixed to some device (not shown) that moves to the right along the track at a speed of 2.0 mm/frame. If in the Earth reference frame cart 2 again moves at +3.6 mm/frame and cart 1 is again at rest, what are the cart velocities according to an observer moving along with ruler C?

1 GETTING STARTED If I arbitrarily let ruler C start in the position shown in frame 1 of Figure 6.2*b*—the zero mark on ruler C aligned with the front of cart 2—this ruler is shifted 2.0 mm to the right in the second frame and another 2.0 mm to the right in each successive frame. I

CONCEPTS

Figure 6.3 Position-versus-frame graphs for the carts of Figure 6.2 as determined from readings on (*a*) ruler A and (*b*) ruler B.



have to use the readings from this ruler to determine the cart velocities.

2 DEVISE PLAN I begin by making a table showing the position of each cart in each frame according to an observer moving along with ruler C. Because the ruler moves 2.0 mm to the right in each frame, I can obtain the readings on this ruler by subtracting 2.0 mm from each cart position in frame 2 of Figure 6.2*a*, subtracting 4.0 mm from each cart position in frame 3, subtracting 6.0 mm from each cart position in frame 4, and so on. I can then use these positions to make a position-versus-frame graph like the ones in Figure 6.3 and determine the velocities of the carts from the slopes of the curves.

3 EXECUTE PLAN My table of the cart positions measured with ruler C is shown in **Figure 6.4**. By plotting these data, I see that the x component of the velocity of cart 1 is -2.0 mm/frame and that of cart 2 is $+1.6$ mm/frame. ✔

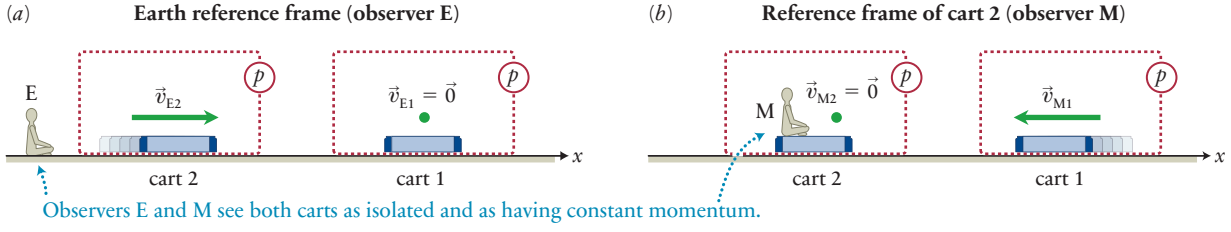
Figure 6.4

x_{M2} (mm)	x_{M1} (mm)
0	22.5
1.6	20.5
3.2	18.5
4.8	16.5
6.4	14.5

4 EVALUATE RESULT The observer moving with ruler C sees cart 1 moving to the left, meaning that the x component of its velocity should be negative, as I found. This observer and cart 2 both move in the positive x direction in the Earth reference frame, but the speed of cart 2 is higher than that of ruler C, and so cart 2 moves to the right relative to the observer. Therefore the x component of its velocity should be positive, in agreement with what I found. Because the velocity of ruler C is different from the velocity of either cart, neither cart is at rest relative to ruler C.

This example and the text preceding it show that motion is a relative concept. In the Earth reference frame, cart 1 is at rest and cart 2 is moving. Relative to the moving ruler in Figure 6.2*b*, cart 1 is moving and cart 2 is at rest. And relative to the ruler of Example 6.1, both carts are moving. In all three reference frames, however, we discover that the carts move at constant velocity. We could just as well have used a ruler moving at $+1.0$ mm/frame, $+4.0$ mm/frame, -0.1 mm/frame, or any other constant velocity. In each case, we would reach the same conclusion: The carts move at constant velocity. So, if an object moves at constant velocity in the Earth reference frame, its motion observed from *any reference frame moving at constant velocity relative to Earth* is also at constant velocity.

Comparing Figures 6.3*a* and 6.3*b*, we see that the x component of each cart's velocity according to ruler A (Figure 6.3*a*) is 3.6 mm/frame higher than the velocity according to ruler B (Figure 6.3*b*). So, an object's velocity $\vec{v}_{Ao}$ determined from the readings on ruler A is equal to the sum of the velocity $\vec{v}_{AB}$ of ruler B relative to ruler A and the velocity $\vec{v}_{Bo}$ of the object relative to ruler B: $\vec{v}_{Ao} = \vec{v}_{AB} + \vec{v}_{Bo}$. For cart 1, we have $0 = +3.6$ mm/frame $+ (-3.6$ mm/frame); for cart 2, $+3.6$ mm/frame $= +3.6$ mm/frame $+ 0$. You can readily verify that the same is true for the velocities determined with ruler C in Example 6.1.



6.1 What is the velocity of each cart in Figure 6.2 measured by an observer moving at -3.0 mm/frame in the Earth reference frame?

6.2 Inertial reference frames

How does the choice of reference frame affect our accounting methods for momentum and energy? To answer this question, let's consider the two carts of Figure 6.2 from the point of view of two observers. To an observer E, who is at rest relative to Earth, cart 1 is at rest and cart 2 is moving at constant velocity (**Figure 6.5a**). To an observer M, who is moving along with cart 2, cart 2 is at rest and cart 1 is moving at constant velocity (Figure 6.5*b*). Even though the observers obtain different values for the carts' velocities, these

CONCEPTS

Figure 6.5 The carts of Figure 6.2 seen by (*a*) an observer in the Earth reference frame and (*b*) an observer moving along with cart 2.

values are constant, and therefore both observers conclude that the momentum of each cart is constant. Both observers also agree that the two carts are isolated, which means that conservation of momentum yields $\Delta\vec{p} = \vec{0}$ (Eq. 4.17) for each cart, in agreement with their observations.

6.2 From the point of view of each observer in Figure 6.5, (*a*) is the energy of each cart constant? (*b*) Is the isolated system containing cart 1 closed? (*c*) Is the isolated system containing cart 2 closed?

Although we checked for only the simple case of carts moving at constant velocity on a low-friction track, Figure 6.5 and Checkpoint 6.2 suggest that the accounting procedures and principles we introduced in the preceding two chapters can be applied in any reference frame moving at constant velocity relative to Earth. Indeed, when we are moving at constant velocity relative to Earth, things around us behave the same way they behave when we are at rest on the ground. For example, imagine being in a plane flying at a constant speed of 260 m/s in a straight line. The surface of the coffee in the cup in front of you looks no different from the way it looks at home. If you drop your keys, they fall straight down just as they would if the plane were at rest on the ground. And when the flight attendant pours coffee into your cup while you all move at 260 m/s, you don't expect him to spill it on you any more than you do when a waiter pours your coffee in a restaurant.

In fact, if the engines are very quiet, the ride is smooth, the cabin is closed, and the window shades are down, it is impossible for you to determine whether or not the plane is moving. Here is the simplest possible experiment: Put a marble on the floor of the plane. Provided the floor is level relative to the ground, the marble remains at rest where you placed it. This is true whether the plane is at rest or cruising at a constant 260 m/s. When the plane is sitting at the gate, inertia keeps the marble at rest relative to the floor (which is at rest relative to the ground), and so $\vec{a} = \vec{0}$. In the air, inertia keeps the marble moving along with the plane at a constant velocity relative to the ground (or, put differently, inertia keeps the marble at rest relative to the floor), and so again $\vec{a} = \vec{0}$.

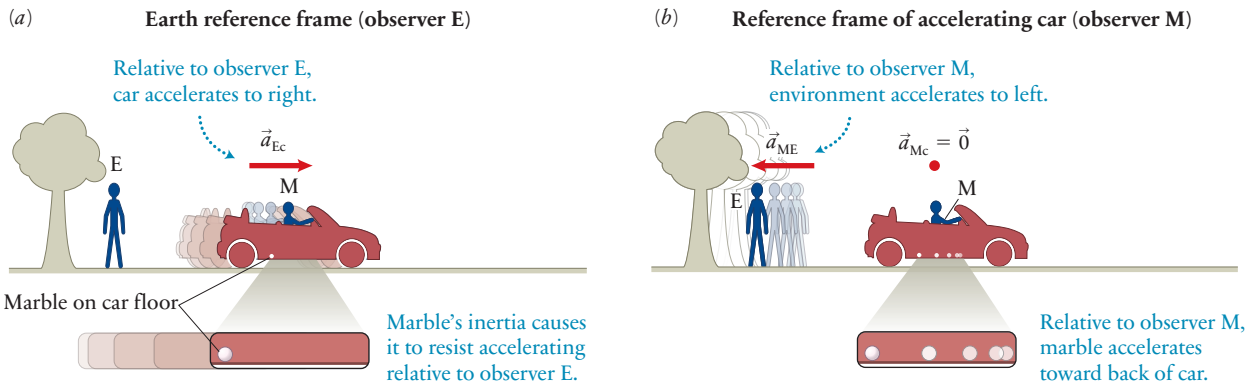
The Earth reference frame or any reference frame moving at constant velocity relative to Earth is called an **inertial reference frame.** We can tell whether or not a reference frame is inertial by testing whether or not the **law of inertia** holds:

> **In an inertial reference frame, any isolated object that is at rest remains at rest, and any isolated object in motion keeps moving at a constant velocity.**

The law of inertia does not hold in a reference frame that is accelerating relative to Earth. For example, imagine sitting in the passenger seat of a car moving at constant velocity with a marble on the floor near your feet. As long as the car is on a horizontal surface and keeps going straight at a constant speed, the marble remains at rest. When the driver suddenly accelerates forward, however, everything in the car lurches backward, with the marble probably ending up somewhere in the back of the car. According to an observer at rest in the Earth reference frame (**Figure 6.6*a***), the marble resists being accelerated forward because of its inertia, and unless you have glued it to the floor or restrained it in some other way, it fails to keep up with the accelerating car. Seen from inside the car, the isolated marble suddenly accelerates backward, and so the law of inertia does not hold in the reference frame of the accelerating car (Figure 6.6*b*). Reference frames in which the

CONCEPTS

Figure 6.6 Motion of a marble in an accelerating car viewed from (*a*) the Earth reference frame and (*b*) a reference frame affixed to the car. $\vec{a}_{Ec}$ is the Earth observer's measurement of the car's acceleration, $\vec{a}_{ME}$ is the moving observer's measurement of Earth's acceleration, and $\vec{a}_{Mc}$ is the moving observer's measurement of the car's acceleration.



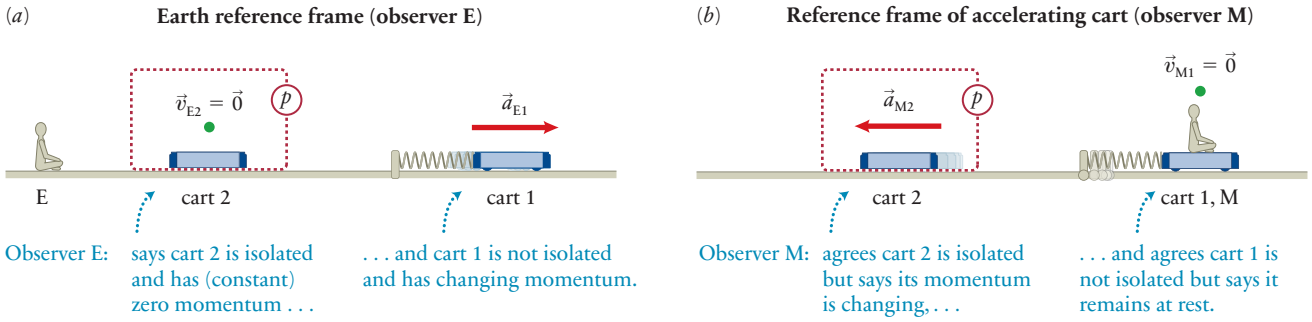


Figure 6.7 A stationary cart and an accelerating cart viewed from (*a*) the Earth reference frame and (*b*) a reference frame affixed to the accelerating cart.

law of inertia does not hold are called *noninertial reference frames*.

We have singled out the Earth reference frame as the basic inertial reference frame. There is nothing fundamentally special about the Earth reference frame, however, other than that we perform most experiments in this frame. Strictly speaking, Earth is not an inertial reference frame because it revolves around a north-south axis and orbits the Sun in a nearly circular orbit. Because motion on a curved path means that the direction of the velocity is changing and so the velocity is not constant, Earth is accelerating and therefore is a noninertial reference frame. For most cases, the acceleration is too small to be noticeable, and so we may, for most practical purposes, consider the Earth reference frame to be inertial.

EXERCISE 6.2 Inertial or not?

Which of these reference frames are inertial: one affixed to (*a*) a merry-go-round, (*b*) the space shuttle orbiting Earth, (*c*) an airplane taking off, (*d*) a train moving at constant speed along a straight track?

SOLUTION (*b*) and (*d*). If I imagine placing a marble at rest in each reference frame and then observing the marble's motion, I can tell whether the law of inertia holds in that reference frame. From experience, I know that a marble remains at rest on the floor of a train moving at constant speed along a straight track, and so the train's reference frame is inertial. I also know that a marble moves away from where I place it on a merry-go-round and in an airplane taking off, so those reference frames are noninertial. Having never been on the space shuttle, I have no direct experience with such a reference frame. However, I have seen astronauts and objects floating in the space shuttle, and this motion suggests that objects stay at rest or keep moving as the law of inertia states, suggesting that the reference frame of the shuttle is inertial.* ✔

*Just like the Earth reference frame, the shuttle reference frame is only approximately inertial.

Our accounting procedures for momentum and energy cannot be used in noninertial reference frames. Consider, for example, the two carts shown in **Figure 6.7**. Cart 1 is being accelerated by a spring, and cart 2 is at rest in the Earth reference frame. Cart 2 constitutes an isolated system, but cart 1 is not isolated because it interacts with the spring. To observer E in the Earth reference frame (Figure 6.7*a*), the behavior of both carts is in agreement with the momentum law: The momentum of the nonisolated cart 1 changes, while the momentum of the isolated cart 2 is constant. For observer M, however, who is accelerating along with cart 1 (Figure 6.7*b*), things don't quite add up. From this observer's perspective, cart 1 remains at rest even though it interacts with the spring, and the momentum of cart 2 changes even though that cart is isolated. Equations 4.17 ($\Delta\vec{p} = \vec{0}$) and 5.23 ($\Delta E = 0$), which embody the laws of conservation of momentum and energy, do not hold in the noninertial reference frame of observer M in Figure 6.7*b*.

Are we going to run into problems because the laws of the universe are different in noninertial reference frames? No, because nothing prescribes the reference frame; we get to choose it. So for now we just avoid using noninertial reference frames. For the accelerating car, for instance, we would choose not a reference frame affixed to the car but the Earth reference frame.

6.3 From the point of view of each observer in Figure 6.7, (*a*) is the energy of each cart constant? (*b*) Is the isolated system containing cart 1 closed? (*c*) Is the isolated system containing cart 2 closed? (*d*) Do the observations made by each observer agree with the conservation of energy law?

6.3 Principle of relativity

In the preceding section, we saw that the conservation laws apply for single objects in inertial reference frames. Let us now test the conservation laws for interacting objects.

CONCEPTS

Figure 6.8 Velocity-versus-time graphs for two carts colliding on a low-friction track as seen (*a*) from the Earth reference frame and (*b*) from a reference frame moving along the track at $v_{EMx} = -0.20$ m/s relative to Earth. The inertias are 0.36 kg for cart 1 and 0.12 kg for cart 2.

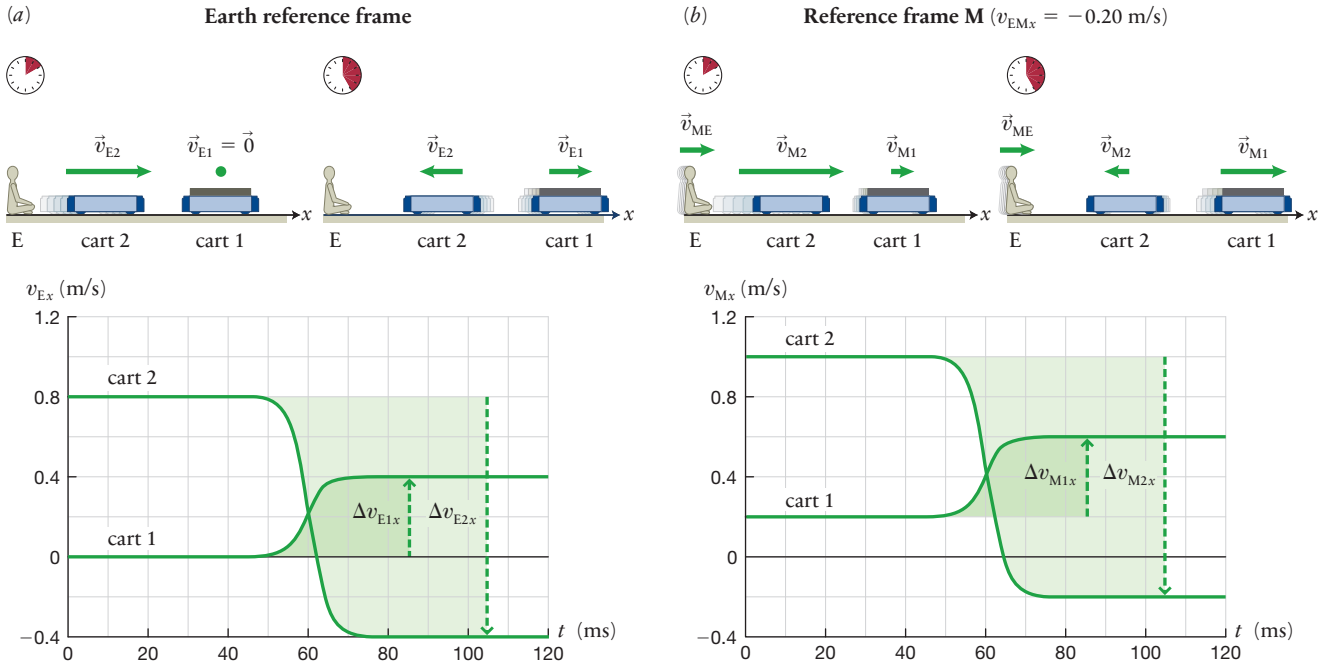

Figure 6.8 shows velocity-versus-time graphs for two-cart collisions. The values in Figure 6.8*a* were measured by an observer in the Earth reference frame. As you saw in Checkpoint 6.1, we can obtain the velocities of the carts in reference frame M of Figure 6.8*b* by subtracting the velocities in reference frame M from the velocities in the Earth reference frame. Because reference frame M in Figure 6.8*b* moves at a constant −0.20 m/s relative to Earth, we must subtract −0.20 m/s (that is, add 0.20 m/s) from the x component of each velocity in the Earth reference frame to obtain the corresponding velocity in reference frame M.

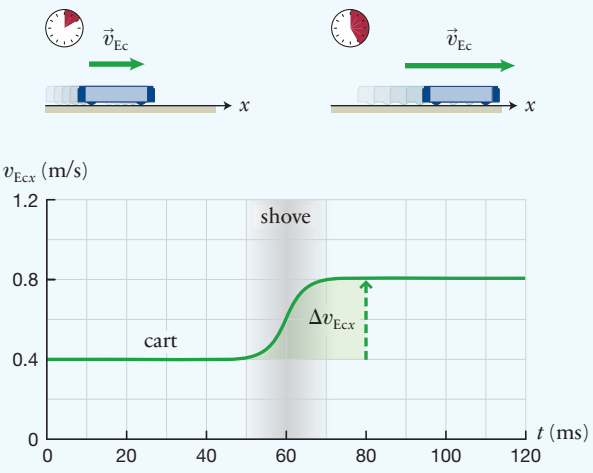
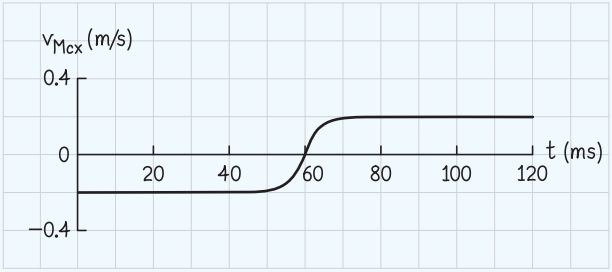
The only difference between Figures 6.8*a* and 6.8*b* is that the curves in Figure 6.8*b* are shifted upward by 0.20 m/s, the relative speed of the two reference frames. However, the *changes* in the x components of the cart's velocities, Δv_{1x} and Δv_{2x}, are not affected by the velocity of reference frame M. Because the inertia of any object is not affected by the motion of an observer studying the object, we observe that the changes in the x component of the carts' momenta, $\Delta p_{1x} = m_1 \Delta v_{1x}$ and $\Delta p_{2x} = m_2 \Delta v_{2x}$, are the same in both reference frames. So, because conservation of momentum requires that $\Delta \vec{p} = \vec{0}$ in the Earth reference frame, we also obtain $\Delta \vec{p} = \vec{0}$ in reference frame M.



If reference frame M in Figure 6.8*b* had moved at any other constant velocity relative to Earth, the vertical shift of the curves would be different but the shape of the curves would be the same. Again we would obtain the same momentum changes for the two carts, and again we would conclude that the collision does not change the momentum of the system. So, if the change in the system momentum is zero in the Earth reference frame, it must be zero in all reference frames moving at a constant velocity relative to Earth. Experiments show that this statement can be extended to any inertial reference frame, not just the Earth reference frame.

CONCEPTS

EXAMPLE 6.3 Momentum shove



A 0.12-kg cart moving on a straight, low-friction track gets a shove so that its speed changes. Its initial and final speeds measured in the Earth reference frame are 0.40 m/s and 0.80 m/s (**Figure 6.9**). Determine the change in the cart's momentum as seen from (*a*) the Earth reference frame and (*b*) a reference frame M moving in the same direction as the cart at a speed of 0.60 m/s relative to the track.

Figure 6.9 Example 6.3.

1 GETTING STARTED To determine the momentum change in either case, I need to know the cart's initial and final velocities in the two reference frames. In the Earth reference frame, $v_{\mathrm{Ec}x,\mathrm{i}} = +0.40$ m/s and $v_{\mathrm{Ec}x,\mathrm{f}} = +0.80$ m/s. In reference frame M, which moves at $v_{\mathrm{ME}x} = +0.60$ m/s relative to Earth, these values are 0.60 m/s lower: $v_{\mathrm{Mc}x,\mathrm{i}} = -0.20$ m/s and $v_{\mathrm{Mc}x,\mathrm{f}} = +0.20$ m/s. I then make a velocity-versus-time graph for the cart as viewed from reference frame M (**Figure 6.10**).

Figure 6.10

2 DEVISE PLAN Now that I have the x components of the initial and final velocities in both reference frames, I can calculate the x components of the initial and final momenta and determine the change in momentum.

3 EXECUTE PLAN (*a*) In the Earth reference frame, the x components of the initial and final momenta are $p_{\mathrm{Ec}x,\mathrm{i}} = mv_{\mathrm{Ec}x,\mathrm{i}} = (0.12\ \mathrm{kg})(+0.40\ \mathrm{m/s}) = +0.048\ \mathrm{kg \cdot m/s}$ and $p_{\mathrm{Ec}x,\mathrm{f}} = mv_{\mathrm{Ec}x,\mathrm{f}} = (0.12\ \mathrm{kg})(+0.80\ \mathrm{m/s}) = +0.096\ \mathrm{kg \cdot m/s}$. So the x component of the change in momentum is $\Delta p_{\mathrm{Ec}x} = (+0.096\ \mathrm{kg \cdot m/s}) - (+0.048\ \mathrm{kg \cdot m/s}) = +0.048\ \mathrm{kg \cdot m/s}$. ✔

(*b*) In reference frame M, $p_{\mathrm{Mc}x,\mathrm{i}} = mv_{\mathrm{Mc}x,\mathrm{i}} = (0.12\ \mathrm{kg}) \times (-0.20\ \mathrm{m/s}) = -0.024\ \mathrm{kg \cdot m/s}$ and $p_{\mathrm{Mc}x,\mathrm{f}} = mv_{\mathrm{Mc}x,\mathrm{f}} = (0.12\ \mathrm{kg})(+0.20\ \mathrm{m/s}) = +0.024\ \mathrm{kg \cdot m/s}$. So $\Delta p_{\mathrm{Mc}x} = (+0.024\ \mathrm{kg \cdot m/s}) - (-0.024\ \mathrm{kg \cdot m/s}) = +0.048\ \mathrm{kg \cdot m/s}$. ✔

4 EVALUATE RESULT The momentum change is the same in the two reference frames, as I expect. In reference frame M, the $v_x(t)$ curve shifts up or down, but its shape does not change, and therefore the values of $\Delta\vec{v}$ and $\Delta\vec{p}$ must also remain the same.

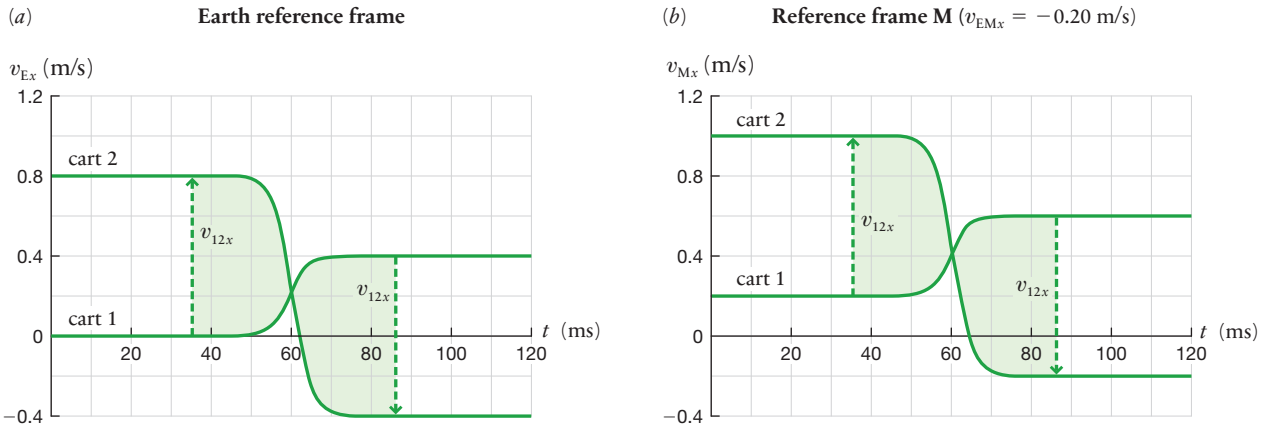
Example 6.3 reaffirms what we have already seen:

The change in a system's momentum is the same in any inertial reference frame.

6.4 In Example 6.3, what is the change in the cart's kinetic energy due to the shove (*a*) in the Earth reference frame, (*b*) in a reference frame moving in the same direction as the cart at 0.60 m/s relative to Earth, and (*c*) in a reference frame moving in the same direction as the cart at 0.80 m/s relative to Earth?

Unlike changes in momentum, changes in kinetic energy are not the same in two reference frames moving relative to each other. As Checkpoint 6.4 shows, the cart's kinetic energy increases, decreases, or stays the same depending on the reference frame.

The observation that changes in kinetic energy depend on the reference frame is disturbing. What does this result imply about conservation of energy? To begin addressing this question, let's look first at an elastic collision, such as the one in Figure 6.8. In **Table 6.1** I have listed the velocities and kinetic energy of both carts. Note that even though the change in velocity Δv_x for each cart is the same in the two reference frames, the change in kinetic energy ΔK for each cart is not. In a given reference frame, however, the absolute value of ΔK is the same for both carts, and so the change in the kinetic energy K of the two-cart system is zero in each frame.



A simple way of arguing that the kinetic energy of the two-cart system *has* to remain unchanged in elastic

CONCEPTS

Table 6.1 An elastic collision seen from two reference frames

		v_x (m/s)				Kinetic energy (10^{-3} J)		
Cart	Inertia (kg)	*before*	*after*	Δv_x		*before*	*after*	ΔK
Earth reference frame								
1	0.36	0	+0.40	+0.40		0	29	+29
2	0.12	+0.80	−0.40	−1.2		38	9	−29
					K	38	38	0
Reference frame moving at −0.20 m/s relative to Earth								
1	0.36	+0.20	+0.60	+0.40		7	65	+58
2	0.12	+1.0	−0.20	−1.2		60	2	−58
					K	67	67	0

Figure 6.11 The relative velocity of the two colliding carts of Figure 6.8 is the same in (*a*) the Earth reference frame and (*b*) a reference frame moving along the track at $v_{EMx} = -0.20$ m/s relative to Earth.

collisions in any inertial reference frame is to look at how we formulated kinetic energy in Chapter 5 in terms of the relative velocities of two objects in a collision. As we saw earlier, differences in velocity do not depend on the velocity of the reference frame (Figure 6.11). In particular, our experimental observation that the relative speed of two colliding objects is unchanged in an elastic collision holds when we measure that relative speed in a reference frame that is moving at constant velocity. More generally, we observe:

The kinetic energy of a system of two elastically colliding objects does not change in any inertial reference frame.

Even though K does not change in elastic collisions, the fact that the individual ΔK values depend on the reference frame could be a big problem for conservation of energy in inelastic collisions. This reference-frame dependence for the individual ΔK values could mean that ΔK for the system also depends on the reference frame. Recall from Section 5.3 that in inelastic collisions some kinetic energy is converted to internal energy, which is a measure of the state of the system. Because changes in kinetic energy are reference-frame-dependent, the amount that gets converted could be reference-frame-dependent as well and that would mean that the final state of the system would depend on the reference frame! To determine whether or not this is the case, we examine an inelastic collision in the next example.

CONCEPTS

EXAMPLE 6.4 Energy conversion

Consider a collision between the two carts of Table 6.1, starting from the same initial velocities, but with $v_{E1x,f} = +0.30$ m/s. Make a table like Table 6.1 for this situation, and compare the amount of kinetic energy converted to internal energy in the Earth reference frame and in a reference frame M moving at -0.20 m/s relative to the track.

1 GETTING STARTED Because all the initial values are the same, I can copy all the "before" values from Table 6.1. I am given the final velocity of cart 1, and so I need to determine the final velocity of cart 2 in the Earth reference frame, then determine the final velocities in reference frame M, calculate the corresponding kinetic energies, and determine the change in kinetic energy in each reference frame.

2 DEVISE PLAN To determine $v_{E2x,f}$, I apply conservation of momentum to the isolated system of the two carts, which tells me that $\Delta\vec{p} = \vec{0}$. To calculate the two final velocities in reference frame M, I subtract the velocity of this reference frame from the carts' velocities in the Earth reference frame. Then I determine the kinetic energies from $K = \frac{1}{2}mv^2$ and complete the table by determining the changes in kinetic energy.

3 EXECUTE PLAN Because $\vec{p}_i = \vec{p}_f$, I have

$$m_1 v_{E1x,i} + m_2 v_{E2x,i} = m_1 v_{E1x,f} + m_2 v_{E2x,f}.$$

Substituting $v_{E1x,i} = 0$ and solving for $v_{E2x,f}$, I get

$$v_{E2x,f} = \frac{m_2 v_{E2x,i} - m_1 v_{E1x,f}}{m_2}.$$

Substituting the given values into this expression, I obtain $v_{E2x,f} = -0.10$ m/s.

Because $v_{EMx} = -0.20$ m/s, I must add 0.20 m/s to the x components of the carts' velocities in the Earth reference frame to determine the corresponding values in reference frame M:

$$v_{M1x,i} = 0 + (+0.20\text{ m/s}) = +0.20\text{ m/s}$$

$$v_{M2x,i} = (+0.80\text{ m/s}) + (+0.20\text{ m/s}) = +1.00\text{ m/s}$$

$$v_{M1x,f} = (+0.30\text{ m/s}) + (+0.20\text{ m/s}) = +0.50\text{ m/s}$$

$$v_{M2x,f} = (-0.10\text{ m/s}) + (+0.20\text{ m/s}) = +0.10\text{ m/s}.$$

Now I can calculate all the kinetic energies and complete the table (Table 6.2). ✔

Table 6.2 An inelastic collision seen from two reference frames

Cart	Inertia (kg)	v_x (m/s) before	v_x (m/s) after	Δv_x	Kinetic energy (10^{-3} J) before	Kinetic energy (10^{-3} J) after	ΔK
Earth reference frame							
1	0.36	0	+0.30	+0.30	0	16	+16
2	0.12	+0.80	−0.10	−0.90	38	1	−37
				K	38	17	−21
Reference frame moving at −0.20 m/s relative to Earth							
1	0.36	+0.20	+0.50	+0.30	7	45	+38
2	0.12	+1.0	+0.10	−0.90	60	1	−59
				K	67	46	−21

4 **EVALUATE RESULT** Each cart's kinetic energy change is different in the two reference frames because, as just noted in the text, changes in kinetic energy are reference-frame-dependent. However, the change in the *system's* kinetic energy is the same in the two reference frames: −21 mJ in both cases. This tells me that the amount of kinetic energy converted to internal energy—and therefore the final state of the two carts—does not depend on the reference frame, as I expect.

6.5 Repeat Example 6.4 but let the collision be totally inelastic.

The results of Example 6.4 and Checkpoint 6.5 are reassuring. Imagine that the converted kinetic energy becomes thermal energy, with the result that the temperature of each cart increases. You wouldn't expect these temperature changes to be different when you view the collision from reference frames that are moving at constant speed relative to each other. Likewise, in a collision between two cars, where the converted kinetic energy goes into crushing the fenders, you wouldn't expect the bending of the metal to depend on the reference frame. The amount of kinetic energy converted to internal energy during an inelastic collision does not depend on the velocity of the reference frame relative to the colliding objects.

These observations, together with the results we obtained in the examples in this section, tell us that the same laws and principles we discussed in Chapters 4 and 5 hold in any inertial reference frame. In particular, the momentum and energy laws can be used in any inertial reference frame. Earlier we saw that it is not possible to tell the difference between various inertial reference frames—that is, reference frames in which the law of inertia holds. It is an experimental fact that things behave the same way in all inertial reference frames. We should therefore expect the laws that describe that behavior to be the same too. This leads us to formulate the **principle of relativity:**

The laws of the universe are the same in all inertial reference frames, which move at constant velocity relative to each other.

The principle of relativity provides a criterion for judging theories: For a theory to be valid, it must prescribe the same behavior in all inertial reference frames. Although observers in different inertial reference frames record different values for the velocities of carts involved in a collision and therefore different momenta and kinetic energies, they agree that the momentum and energy of the two-cart system do not change.

It follows from the principle of relativity that no experiment carried out entirely in one inertial reference frame can tell what the motion of that reference frame is relative to another reference frame. Returning to the example of Section 6.2: Sitting in a very quiet airplane during a smooth, turbulence-free ride, it is impossible to tell if you are flying or if the airplane is sitting on the runway with its engines running. Of course, you can tell you are moving relative to Earth's surface by peeking out of the window and observing the landscape move by. By timing the motion of some reference points on Earth, you could even determine the velocity of the airplane relative to Earth. By peeking out of the window, however, your observations are no longer confined to a single reference frame. To determine your velocity relative to Earth's surface, you need to take measurements in two reference frames.

A consequence of the principle of relativity is that it is not possible to deduce from measurements taken entirely in one reference frame the motion of that reference frame relative to other reference frames.

This statement also means that no inertial reference frame is preferred over any other; it is not possible to determine the *absolute* velocity of any reference frame or object. The laws of the universe are the same in all inertial reference frames, and there is no reference frame that is "at rest" in some absolute sense.

CONCEPTS

When you are standing on Earth's surface, are you "at rest" or moving at 30 km/s (the speed of Earth in its orbit around the Sun), or is your speed higher still—say, the speed of the Sun in its galactic orbit? None of these statements is meaningful because no experiments can be done to determine your speed in empty space. You can only speak of your velocity or speed *relative to something else*.

When specifying the velocity of an object, we must therefore always state relative to what we measure that velocity. For simplicity, when the Earth reference frame is the only reference frame of interest, we will omit this relative statement and the subscript E. The phrase "his velocity was $\vec{v}$" will be understood to mean the velocity is measured relative to Earth.

6.6 Is the coefficient of restitution e different in two inertial reference frames, which are moving at constant velocity relative to each other? (See Eq. 5.18 if you have forgotten the definition of e.)

6.4 Zero-momentum reference frame

Let me end this first part of the chapter by addressing a practical question. If you can choose whichever inertial reference frame you wish, is any choice better than another? The reference frame you are in (usually one at rest relative to Earth) is a logical choice. By choosing some other reference frame, however, you could adjust the value of the momentum of a system up or down by some fixed amount without violating the conservation laws. You could, for instance, adjust the velocity of your reference frame in such a way that the momentum of the system you are observing becomes zero. Such a reference frame is called the system's **zero-momentum reference frame.** To distinguish the zero-momentum reference frame from other reference frames, we'll refer to quantities measured in that reference frame with the capital letter Z. As we shall see, examining collisions from this reference frame often simplifies things.

The prescription for calculating the velocity of the zero-momentum reference frame is as follows:

The velocity $\vec{v}_{EZ}$ of a system's zero-momentum reference frame relative to Earth is equal to the momentum of the system in the Earth reference frame divided by the inertia of the system.

EXAMPLE 6.5 Zeroing out the momentum

For the colliding carts in Figure 6.8, (*a*) determine the velocity of the zero-momentum reference frame relative to Earth and (*b*) show that the system momentum measured in the zero-momentum reference frame is zero both before and after the collision.

1 GETTING STARTED This example requires me to apply the prescription for calculating the velocity of the zero-momentum reference frame and then verify that the system momentum is indeed zero in that reference frame.

2 DEVISE PLAN To determine the velocity of the zero-momentum reference frame relative to Earth, I calculate the momentum of the two-cart system in the Earth reference frame and then divide this result by the sum of the inertias of the two carts.

Once I have determined the velocity of the zero-momentum reference frame, I subtract it from the carts' velocities in the Earth reference frame to obtain their velocities in the zero-momentum reference frame. I then use these velocities to calculate the carts' initial and final momenta.

3 EXECUTE PLAN (*a*) In the Earth reference frame, cart 1 (inertia 0.36 kg) is initially at rest and cart 2 (inertia 0.12 kg) is moving at +0.80 m/s. The x component of the combined momentum of the two carts is therefore $(0.12\ \text{kg})(+0.80\ \text{m/s}) = +0.096\ \text{kg}\cdot\text{m/s}$. The x component of the velocity of the zero-momentum reference frame is thus

$$\frac{0.096\ \text{kg}\cdot\text{m/s}}{0.36\ \text{kg} + 0.12\ \text{kg}} = +0.20\ \text{m/s}. \checkmark$$

(*b*) To obtain the x component of the velocities of the carts in the zero-momentum reference frame, I must subtract 0.20 m/s from their values in the Earth reference frame: $v_{Z1x,i} = -0.20\ \text{m/s}$ and $v_{Z2x,i} = +0.60\ \text{m/s}$. Then $p_{Z1x,i} = -0.072\ \text{kg}\cdot\text{m/s}$ and $p_{Z2x,i} = +0.072\ \text{kg}\cdot\text{m/s}$, making the initial momentum of the system measured from this reference frame zero. ✔

For the x component of the final velocities in the zero-momentum reference frame, I get $v_{Z1x,f} = +0.20\ \text{m/s}$ and $v_{Z2x,f} = -0.60\ \text{m/s}$. So $p_{Z1x,f} = +0.072\ \text{kg}\cdot\text{m/s}$ and $p_{Z2x,f} = -0.072\ \text{kg}\cdot\text{m/s}$, making the system's final momentum measured from this reference frame zero. ✔

4 EVALUATE RESULT In the zero-momentum reference frame, the momentum of the two-cart system before the collision is zero, as it must be from the definition of the zero-momentum frame. I also observe that it is zero after the collision, as I expect given that the system is isolated.

Figure 6.12 and Table 6.3 summarize the results of Example 6.5. Note how the shift from the Earth reference frame to the zero-momentum reference frame increases symmetry in the momentum-versus-time graph. In the zero-momentum reference frame, the velocity and momentum of each cart simply change sign in the collision. In this frame, the system as a whole is at rest, allowing us to concentrate on the motion of the objects within the system.

6.7 Is the kinetic energy of the two-cart system in Figure 6.12 in the zero-momentum reference frame less than, equal to, or greater than the system's kinetic energy in the Earth reference frame?

CONCEPTS

Figure 6.12 Collision between two carts as seen (*a*) from the Earth reference frame and (*b*) from the zero-momentum reference frame. The inertias of the carts are $m_1 = 0.36$ kg and $m_2 = 0.12$ kg and the x axis points to the right in the diagrams.

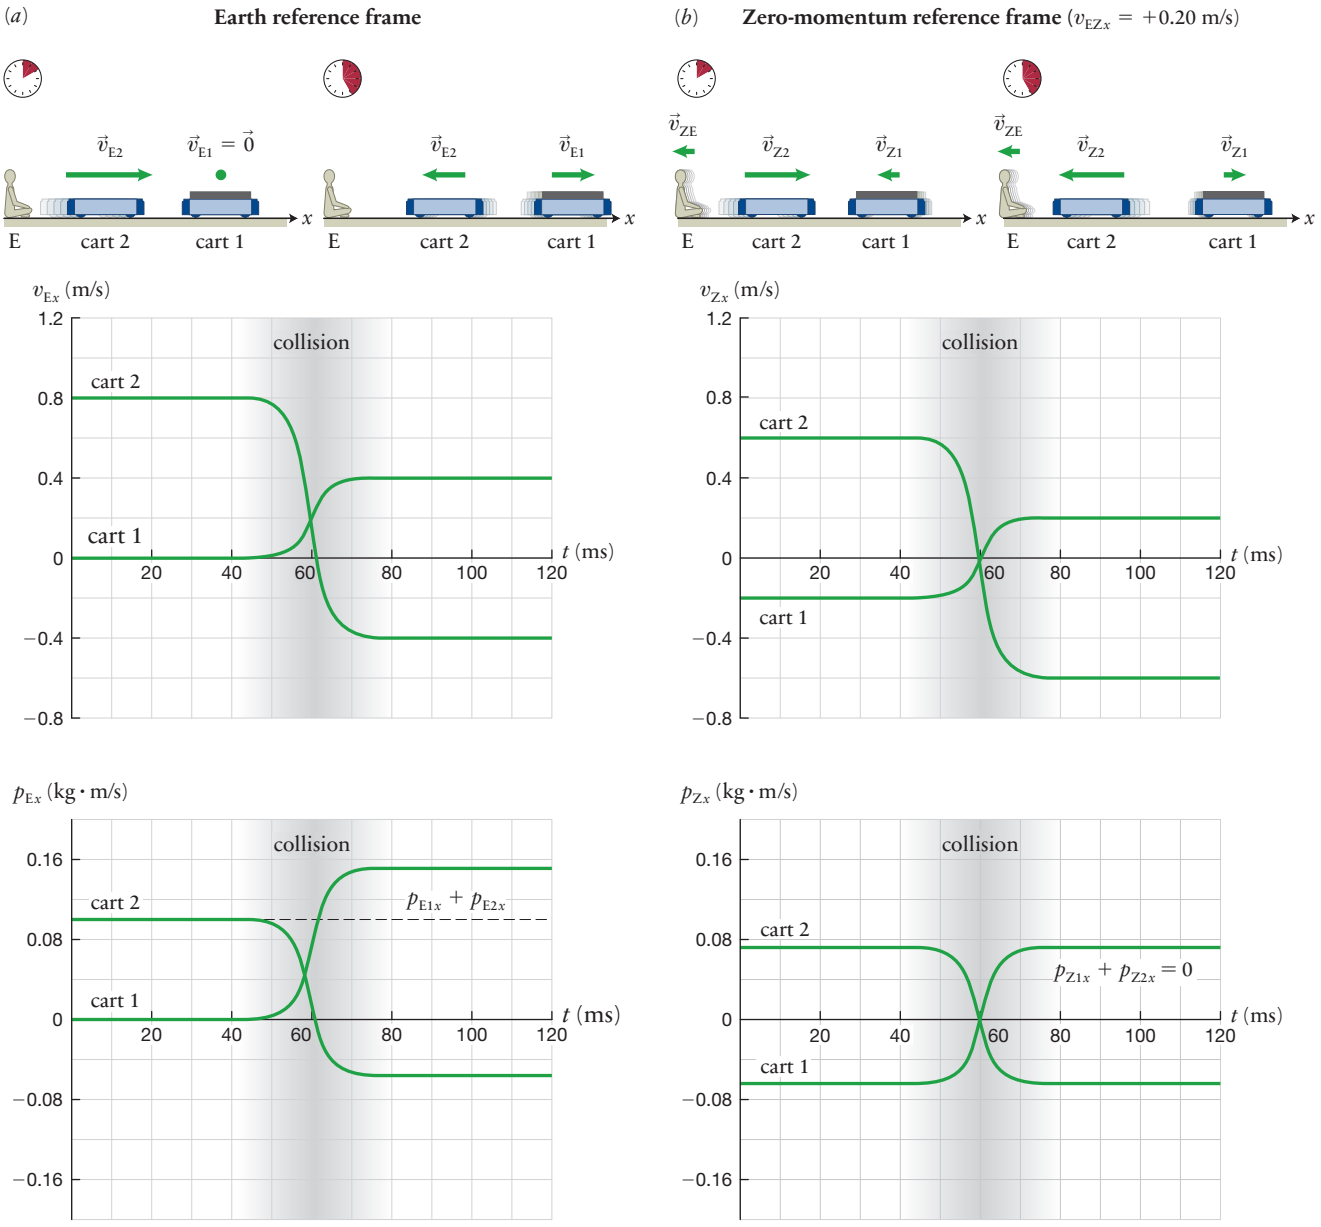


Table 6.3 Symmetry in a zero-momentum reference frame

	Velocity change (m/s)		Momentum change (kg · m/s)	
Cart	Earth reference frame	Zero-momentum reference frame	Earth reference frame	Zero-momentum reference frame
1	$0 \rightarrow +0.40$	$-0.20 \rightarrow +0.20$	$0 \rightarrow +0.14$	$-0.072 \rightarrow +0.072$
2	$+0.80 \rightarrow -0.40$	$+0.60 \rightarrow -0.60$	$+0.096 \rightarrow -0.048$	$+0.072 \rightarrow -0.072$

Self-quiz

1. A space traveler discovers an object that accelerates in her reference frame. Which conclusion is correct? (*a*) Her reference frame is noninertial. (*b*) The object is not isolated. (*c*) You cannot tell.
2. A jogger starts from rest along a straight track. Consider the jogger-Earth system to be isolated. As the jogger's speed increases, does the speed of Earth change or remain constant?
3. A driver slams on the brakes of a car in which a marble is glued to the dashboard. To an observer standing by the side of the road, the marble slows down and has a nonzero acceleration. This happens because (*a*) the observer is in a noninertial reference frame, (*b*) the marble is not isolated, (*c*) some other reason.
4. Is it always possible to choose a zero-momentum reference frame for an isolated system that contains more than two objects?
5. On a low-friction track, two carts with unequal inertias move toward each other. After the collision, the two stick together and are at rest relative to the track. Before the collision, a zero-momentum reference frame would (*a*) move in the direction of the cart that has the greater inertia, (*b*) move in the direction of the faster cart, (*c*) not move relative to the track. (*d*) Can't tell—you need to know the carts' inertias and velocities.

Answers

1. (*c*). To claim that her reference frame is inertial, you need to know whether or not an *isolated* object remains at rest in that reference frame. From the information given, you don't know whether the object is accelerating because it is not isolated or because the reference frame is noninertial.
2. It changes. Strange as it sounds, Earth's velocity does change every time you start moving! Otherwise, conservation of momentum would not hold. Can you verify this statement experimentally? Not for the jogger-Earth case, because the ratio $\Delta v_{\text{jogger}}/\Delta v_{\text{Earth}}$ is equal to the inverse ratio of the inertias. Because Earth's inertia is enormous, its velocity change is infinitesimally small. This being so, how can you be sure you have the correct answer? Certainty comes from knowing that the law of conservation of momentum has been found to hold everywhere it has ever been tested—including on a cosmic scale.
3. (*b*). From the point of view of the observer, if the marble were not glued to the dashboard, the inertia of the marble would keep it moving at the velocity it had before the driver hit the brakes. The marble slows down only because the car's dashboard holds it in place. In other words, the dashboard and the marble interact with each other, and therefore the marble is not isolated.
4. Yes. The momentum of any system of objects is the sum of the individual momenta. To obtain the momentum of an object of inertia m_o in a reference frame moving at velocity $\vec{v}_{\text{EM}}$ relative to Earth, we must subtract $m_o\vec{v}_{\text{EM}}$ from the momentum of that object in the Earth reference frame. The system's momentum in that reference frame is then equal to the momentum of the system in the Earth reference frame minus the product $(m_1 + m_2 + m_3 + \cdots)\vec{v}_{\text{EM}}$. We can always choose a velocity $\vec{v}_{\text{EM}}$ such that the magnitude of this product is equal to the magnitude of the momentum of the system in the Earth reference frame and the algebraic signs are opposites.
5. (*c*). After the collision, both carts come to rest in the reference frame of the track, which means that the momentum of the two-cart system after the collision is zero. This means that the system's momentum before the collision was also zero. Therefore the reference frame of the track is a zero-momentum reference frame.

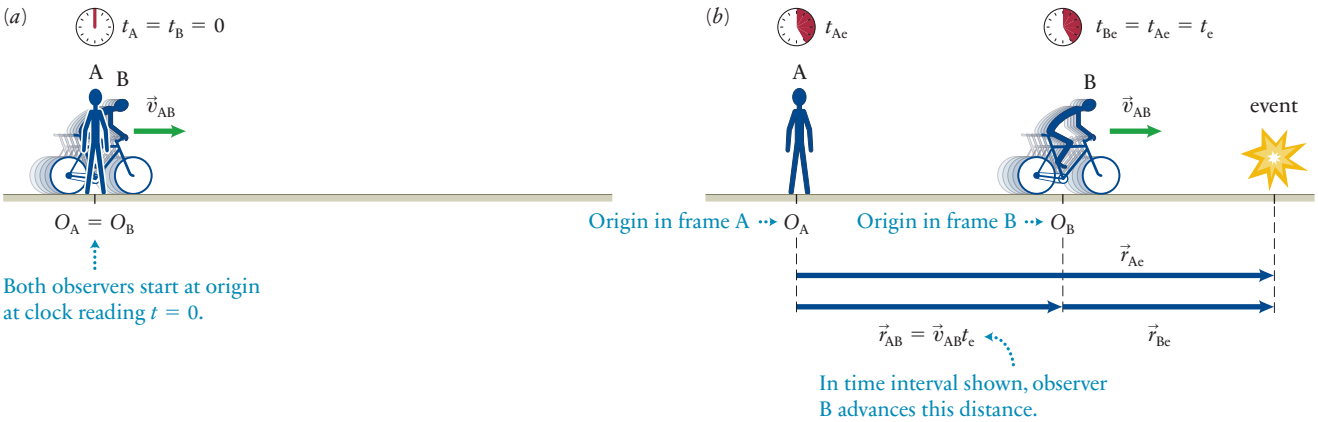
6.5 Galilean relativity

Consider two observers, A and B, moving at constant velocity relative to each other. Suppose they observe the same *event*—such as a firecracker exploding—and describe it relative to their respective reference frames and clocks (**Figure 6.13**). Let the origins of the two observers' reference frames coincide at $t = 0$ (Figure 6.13*a*). Observer A sees the event as happening at position $\vec{r}_{Ae}$ at clock reading t_{Ae} (Figure 6.13*b*).* Observer B sees the event at position $\vec{r}_{Be}$ at clock reading t_{Be}. What is the relationship between these clock readings and positions?

If, as we discussed in Chapter 1, we assume time is absolute—the same everywhere—and if the two observers have synchronized their (identical) clocks, they both observe the event at the same clock readings, which means

$$t_{Ae} = t_{Be}. \tag{6.1}$$

Because the clock readings of the two observers always agree, we can omit the subscripts referring to the reference frames:



$$t_A = t_B = t. \tag{6.2}$$

From Figure 6.13 we see that the position $\vec{r}_{AB}$ of observer B in reference frame A at instant t_e is equal to B's displacement over the time interval $\Delta t = t_e - 0 = t_e$, and so $\vec{r}_{AB} = \vec{v}_{AB}t_e$ because B moves at constant velocity $\vec{v}_{AB}$. Therefore

$$\vec{r}_{Ae} = \vec{r}_{AB} + \vec{r}_{Be} = \vec{v}_{AB}t_e + \vec{r}_{Be}. \tag{6.3}$$

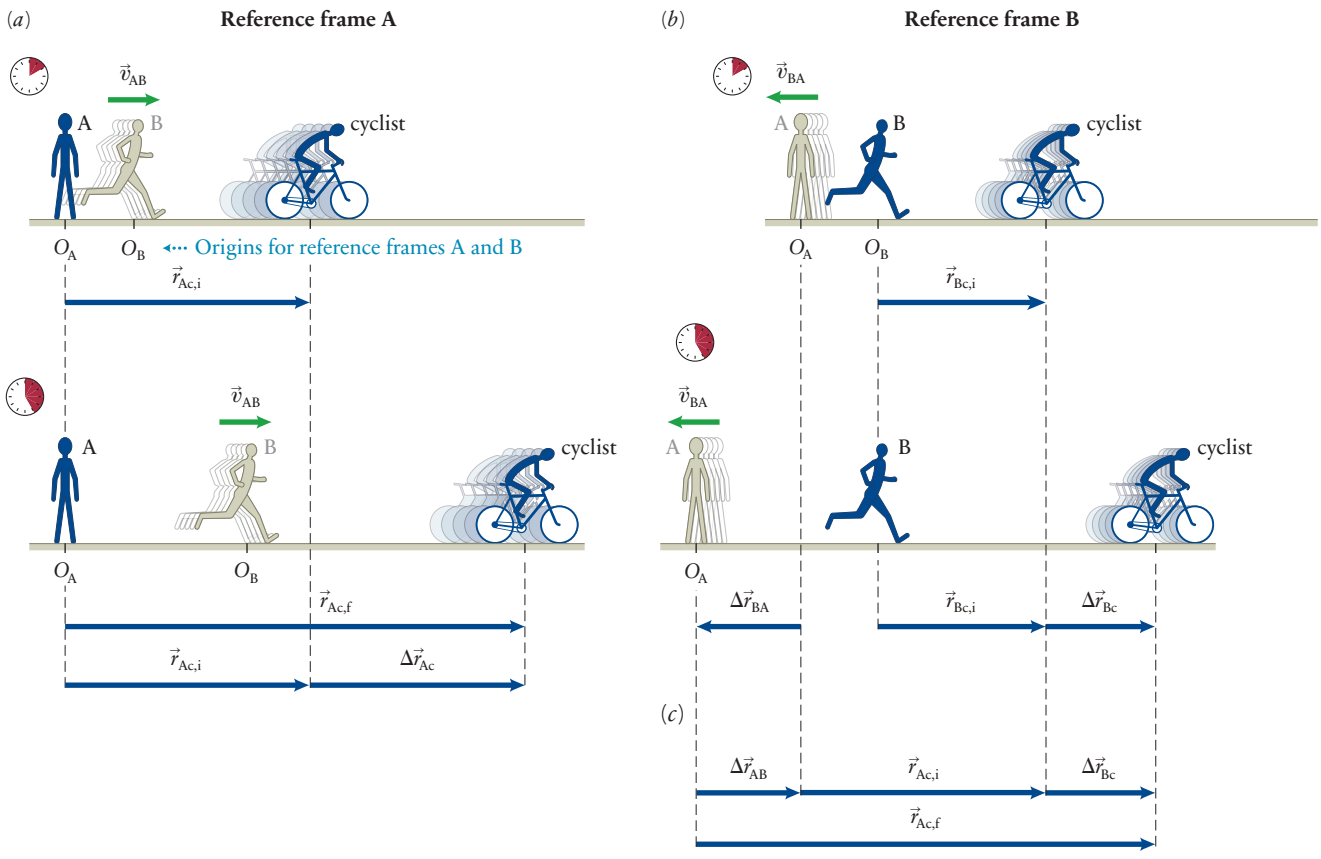
Equations 6.2 and 6.3 allow us to relate event data collected in one reference frame to data on the same event e collected in a reference frame that moves at constant velocity relative to the first one (neither of these has to be at rest relative to Earth, but their origins must coincide at $t = 0$). To this end we

Figure 6.13 Two observers moving relative to each other observe the same event. Observer B moves at constant velocity $\vec{v}_{AB}$ relative to observer A. (*a*) The origins *O* of the two reference frames overlap at instant $t = 0$. (*b*) At instant t_e, when the event occurs, the origin of observer B's reference frame has a displacement $\vec{v}_{AB}t_e$ relative to reference frame A.

*Remember our subscript form: The capital letter refers to the reference frame; the lowercase e is for "event." Thus the vector $\vec{r}_{Ae}$ represents observer A's measurement of the position at which the event occurs.

rewrite these equations so that they give the values of time and position in reference frame B in terms of quantities measured in reference frame A:

$$t_B = t_A = t \tag{6.4}$$



$$\vec{r}_{Be} = \vec{r}_{Ae} - \vec{v}_{AB}t_e. \tag{6.5}$$

These two equations, called the **Galilean transformation equations,** form the basis for *Galilean relativity*; they allow us to relate observations made in different reference frames. The Galilean transformation equations are predicated on the assumption that measurements of time intervals and lengths are not affected by motion. Even though this assumption sounds reasonable, it has been invalidated by experimental confirmation of the theory of special relativity (see Chapter 14). For most everyday phenomena, however, when speeds are much lower than the speed of light (about 3.0×10^8 m/s, see Section 1.3), Eqs. 6.4 and 6.5 remain excellent approximations.

6.8 A jogger runs in place on a treadmill whose belt moves at $v_{EBx} = +2.0$ m/s relative to Earth. Let the origins of the Earth reference frame and the reference frame B moving along with the top surface of the belt coincide at $t = 0$. (*a*) What is the jogger's position in the reference frame of the belt at $t = 10$ s? (*b*) Use Eq. 6.3 to show that an Earth observer's measurement of the jogger's position is $r_{Ejx} = 0$ at all instants.

Now that we have determined the relationship between positions in two reference frames, let us examine the relationship between the velocities of a cyclist relative to two observers, A and B, who are moving at constant velocity $\vec{v}_{AB}$ relative to each other (**Figure 6.14**). Each observer

Figure 6.14 The cyclist's displacement $\Delta\vec{r}_{Ac}$ measured by observer A is different from the displacement $\Delta\vec{r}_{Bc}$ measured by observer B, who is moving relative to observer A.

determines the velocity of the cyclist by measuring the cyclist's displacement during a certain time interval Δt.

According to observer A, the bicycle undergoes a displacement $\Delta\vec{r}_{Ac}$ in the time interval Δt (Figure 6.14*a*). The bicycle's displacement $\Delta\vec{r}_{Bc}$ measured by observer B, however, is different because B undergoes a displacement $\Delta\vec{r}_{AB}$ relative to A (Figure 6.14*b*). Comparing the displacements, we obtain (Figure 6.14*c*)

$$\vec{r}_{Ac,f} - \vec{r}_{Ac,i} = \Delta\vec{r}_{Ac} = \Delta\vec{r}_{AB} + \Delta\vec{r}_{Bc}. \tag{6.6}$$

If we divide the two sides of this equation by the time interval Δt, we obtain

$$\frac{\Delta\vec{r}_{Ac}}{\Delta t} = \frac{\Delta\vec{r}_{AB}}{\Delta t} + \frac{\Delta\vec{r}_{Bc}}{\Delta t}, \tag{6.7}$$

and if we let Δt approach zero, we get

$$\vec{v}_{Ac} = \vec{v}_{AB} + \vec{v}_{Bc}. \tag{6.8}$$

Rewriting this equation so that it gives the velocity of an object o in reference frame B in terms of quantities measured in reference frame A, we get

$$\vec{v}_{Bo} = \vec{v}_{Ao} - \vec{v}_{AB}. \tag{6.9}$$

Equation 6.8 tells us that velocities obtained in different reference frames are additive. If an object moves at a velocity $\vec{v}_{Bo}$ in a reference frame that is moving at a velocity $\vec{v}_{AB}$ relative to some observer A, then the velocity $\vec{v}_{Ao}$ of that object in A's reference frame is the sum $\vec{v}_{AB} + \vec{v}_{Bo}$.

As an example, imagine walking in a train that moves along a straight track at 25 m/s relative to Earth. If you are walking forward at 1.0 m/s relative to the train, what is your velocity relative to Earth? In 1.0 s, the train moves 25 m relative to Earth, and in that same time interval you move that same 25 m plus an additional 1.0 m. Because you move (25 m) + (1.0 m) = 26 m each second, your velocity relative to Earth is 26 m/s.

To determine the relationship between an object's acceleration in the two reference frames, we begin by writing what a change in the object's velocity in reference frame B corresponds to in reference frame A. Using Eq. 6.8 and keeping in mind that the relative velocity $\vec{v}_{AB}$ of the two reference frames is constant, we get

$$\begin{aligned}\Delta\vec{v}_{Ao} &= \vec{v}_{Ao,f} - \vec{v}_{Ao,i} = (\vec{v}_{AB} + \vec{v}_{Bo,f}) - (\vec{v}_{AB} + \vec{v}_{Bo,i}) \\ &= \vec{v}_{Bo,f} - \vec{v}_{Bo,i} = \Delta\vec{v}_{Bo}.\end{aligned} \tag{6.10}$$

In words, *changes in velocity are the same in any two reference frames moving at constant relative velocity*—a conclusion we reached in Section 6.3.

Dividing both sides of Eq. 6.10 by Δt and taking the limit as Δt approaches zero, we determine that the accelerations in the two reference frames are identical, too:

$$\vec{a}_{Ao} \equiv \lim_{\Delta t \to 0} \frac{\Delta\vec{v}_{Ao}}{\Delta t} = \lim_{\Delta t \to 0} \frac{\Delta\vec{v}_{Bo}}{\Delta t} \equiv \vec{a}_{Bo}. \tag{6.11}$$

In particular, if an object moves at constant velocity in the Earth reference frame ($\vec{a}_{Eo} = \vec{0}$), then it moves at constant velocity ($\vec{a}_{Mo} = \vec{0}$) in any reference frame M that moves at constant velocity relative to Earth, confirming what we concluded in Section 6.1.

Two bullet trains passing each other. If each train has a speed of 50 m/s relative to the track, at what speed does the oncoming train approach the one from which the photo is taken?

Answer: 100 m/s.

QUANTITATIVE TOOLS

To simplify working with quantities in various reference frames, note from Figure 6.13*b* that

$$\vec{r}_{Ae} = \vec{r}_{AB} + \vec{r}_{Be} \tag{6.12}$$

The first and last subscripts on either side of this equation are the same, as indicated by the arrows. Moreover, if you imagine canceling the two identical subscripts B that follow each other on the right side and contracting the two vectors $\vec{r}$ into one, you get

$$\vec{r}_{AB} + \vec{r}_{Be} = \vec{r}_{Ae}, \tag{6.13}$$

which is the same as Eq. 6.12. This "subscript cancellation" works with any relative quantity. For example, observer A's measurement of the velocity of an object is equal to observer A's measurement of the velocity of observer B plus observer B's measurement of the velocity of the object:

$$\vec{v}_{Ao} = \vec{v}_{AB} + \vec{v}_{Bo}, \tag{6.14}$$

which is the same as Eq. 6.8.

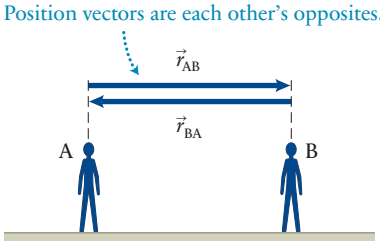


Figure 6.15 shows another useful subscript operation: Reversing the order of the subscripts reverses the direction of a relative vector $\vec{r}_{AB}$. The vector describing the position of observer B relative to A has the same magnitude as the vector $\vec{r}_{BA}$ describing the position of observer A relative to B, but it points in the opposite direction:

$$\vec{r}_{AB} = -\vec{r}_{BA}, \tag{6.15}$$

and by taking the derivative with respect to time of this equation, we obtain a similar expression for the velocity:

$$\vec{v}_{AB} = -\vec{v}_{BA}. \tag{6.16}$$

Figure 6.15 The position vectors of two observers relative to each other are of equal magnitude and point in opposite directions.

PROCEDURE: Applying Galilean relativity

In problems dealing with more than one reference frame, you need to keep track not only of objects, but also of reference frames. For this reason, each quantity is labeled with two subscripts. The first subscript denotes the observer; the second denotes the object of interest. For example, if we have an observer on a train and also a car somewhere on the ground but in sight of the train, then $\vec{a}_{Tc}$ is the train observer's measurement of the acceleration of the car. Once you understand this notation and a few basic operations, working with relative quantities is easy and straightforward.

observer A's measurement of velocity of car:

$$\vec{v}_{Ac}$$

observer ..... object of interest

1. Begin by listing the quantities given in the problem, using this double-subscript notation.
2. Write the quantities you need to determine in the same notation.
3. Use subscript cancellation (Eq. 6.13) to write an equation for each quantity you need to determine, keeping the first and the last subscripts on each side the same. For example, in a problem where you need to determine $\vec{v}_{Tc}$ involving a moving observer B, write

$$\vec{v}_{Tc} = \vec{v}_{TB} + \vec{v}_{Bc}.$$

4. If needed, use subscript reversal (Eq. 6.15) to eliminate any unknowns.
5. Use the kinematics relationships from Chapters 2 and 3 to solve for any remaining unknowns, making sure you stay in one reference frame.

You can use this procedure and the subscript operations for any of the three basic kinematic quantities (position, velocity, and acceleration).

QUANTITATIVE TOOLS

EXAMPLE 6.6 Who is moving?

You are driving at 25 m/s on a straight, horizontal road when a truck going 30 m/s in the same direction overtakes you. Let the positive x direction point in the direction of travel, and let the origins of the reference frames affixed to your car and the truck coincide at the instant the truck overtakes you. (*a*) What is your car's velocity as measured by someone in the truck? (*b*) What is the velocity of the truck relative to your car? (*c*) What is your car's position as measured by someone in the truck 60 s after overtaking you?

❶ **GETTING STARTED** This example involves two reference frames: the Earth reference frame (E) and the reference frame moving along with the truck (T). The velocities of the car and the truck are given in the Earth reference frame: $v_{\mathrm{Ec}x} = +25$ m/s and $v_{\mathrm{ET}x} = +30$ m/s. I need to determine the velocity of my car $\vec{v}_{\mathrm{Tc}}$ relative to the truck, the velocity of the truck $\vec{v}_{\mathrm{cT}}$ relative to my car, and my car's position $\vec{r}_{\mathrm{Tc}}$ relative to the truck 60 s after the overtaking.

❷ **DEVISE PLAN** I begin by using subscript cancellation to write an equation that gives the velocity $\vec{v}_{\mathrm{Tc}}$ of my car relative to the truck in terms of velocities involving the Earth reference frame: $\vec{v}_{\mathrm{Tc}} = \vec{v}_{\mathrm{TE}} + \vec{v}_{\mathrm{Ec}}$. The value of $\vec{v}_{\mathrm{Ec}}$ is given (+25 m/s), but I don't have a value for $\vec{v}_{\mathrm{TE}}$. However, I can use subscript reversal to write $v_{\mathrm{TE}x} = -v_{\mathrm{ET}x} = -30$ m/s. Once I have $\vec{v}_{\mathrm{Tc}}$, I can use subscript reversal once more to determine $\vec{v}_{\mathrm{cT}}$. The product of $\vec{v}_{\mathrm{Tc}}$ and the 60-s time interval gives me $\vec{r}_{\mathrm{Tc}}$ (from Eq. 2.16, $\Delta x = v_x \Delta t$).

❸ **EXECUTE PLAN** (*a*) Using subscript cancellation and reversal, I get $\vec{v}_{\mathrm{Tc}} = \vec{v}_{\mathrm{TE}} + \vec{v}_{\mathrm{Ec}} = -\vec{v}_{\mathrm{ET}} + \vec{v}_{\mathrm{Ec}}$ or, in terms of x components,

$$v_{\mathrm{Tc}x} = -v_{\mathrm{ET}x} + v_{\mathrm{Ec}x} = -(+30\ \mathrm{m/s}) + (+25\ \mathrm{m/s})$$

$$= -5.0\ \mathrm{m/s}. \checkmark$$

(*b*) $v_{\mathrm{cT}x} = -v_{\mathrm{Tc}x} = +5.0$ m/s ✔

(*c*) My displacement in the truck's reference frame is $\Delta x_{\mathrm{Tc}} = (-5.0\ \mathrm{m/s})(60\ \mathrm{s}) = -300$ m. Thus 60 s after the truck passes you, a person in the truck measures your position as $r_{\mathrm{Tc}x} = 300$ m behind the truck. ✔

❹ **EVALUATE RESULT** The truck is moving faster than my car, and so relative to the truck my car moves in the negative x direction, confirming the minus sign on my answers to parts *a* and *c*. Relative to me, the truck moves in the positive x direction, in agreement with the plus sign of my answer to part *b*.

6.9 In a train moving due north at 3.1 m/s relative to Earth, a passenger carrying a suitcase walks due north down the aisle at 1.2 m/s relative to the train. A spider crawls along the bottom of the suitcase at 0.5 m/s due south relative to the suitcase. What is the velocity of the spider relative to Earth?

6.6 Center of mass

To relate momentum in two reference frames moving relative to each other, we must examine inertia. Equation 4.2 told us how to obtain the inertia m_{o} of an object by letting the object collide with the standard inertia:

$$m_{\mathrm{o}} \equiv -\frac{\Delta v_{\mathrm{s}x}}{\Delta v_{\mathrm{o}x}} m_{\mathrm{s}}. \tag{6.17}$$

Suppose this inertia m_{o} is measured by two observers, A and B, who are moving at constant velocity $\vec{v}_{\mathrm{AB}}$ relative to each other. Even though the velocity values measured by the two observers differ, Eq. 6.10 tells us that the moving observer obtains the same velocity changes $\Delta v_{\mathrm{s}x}$ and $\Delta v_{\mathrm{o}x}$ as those measured in the Earth reference frame. This means that we can omit the subscript referring to the reference frame and write

$$m_{\mathrm{Ao}} = m_{\mathrm{Bo}} = m_{\mathrm{o}}. \tag{6.18}$$

Therefore the momenta of an object measured in two reference frames A and B are related by

$$\vec{p}_{\mathrm{Ao}} \equiv m_{\mathrm{o}} \vec{v}_{\mathrm{Ao}} = m_{\mathrm{o}}(\vec{v}_{\mathrm{AB}} + \vec{v}_{\mathrm{Bo}}) \equiv m_{\mathrm{o}} \vec{v}_{\mathrm{AB}} + \vec{p}_{\mathrm{Bo}}, \tag{6.19}$$

where we have used Eq. 6.8 to relate the velocities in the two reference frames. Equation 6.19 shows that the momentum measured in reference

frame B is different from the momentum measured in reference frame A. In particular, if the velocity of reference frame B relative to reference frame A is $\vec{v}_{AB} = \vec{p}_{Ao}/m_o$, the momentum measured in reference frame B is zero: $\vec{p}_{Bo} = \vec{0}$ (and so reference frame B is a zero-momentum reference frame for that object).

We can make the momentum of a system of objects zero in the same way. Suppose we have a system made up of objects that have inertias $m_1, m_2, \ldots$, and we let the momentum of the system in reference frame A be $\vec{p}_{A\,sys}$. Using Eq. 6.19, we can write for the momentum of the system

$$\begin{aligned}\vec{p}_{A\,sys} &= \vec{p}_{A1} + \vec{p}_{A2} + \cdots \\ &= (m_1\vec{v}_{AB} + \vec{p}_{B1}) + (m_2\vec{v}_{AB} + \vec{p}_{B2}) + \cdots \\ &= (m_1 + m_2 + \cdots)\vec{v}_{AB} + (\vec{p}_{B1} + \vec{p}_{B2} + \cdots) = m\vec{v}_{AB} + \vec{p}_{B\,sys}, \quad (6.20)\end{aligned}$$

where $m = m_1 + m_2 + \cdots$ is the inertia of the system. If we adjust the velocity $\vec{v}_{AB}$ of reference frame B relative to reference frame A such that

$$\vec{v}_{AB} = \frac{\vec{p}_{A\,sys}}{m}, \quad (6.21)$$

then, according to Eq. 6.20, reference frame B is a zero-momentum reference frame:

$$\vec{p}_{B\,sys} = \vec{p}_{A\,sys} - m\vec{v}_{AB} = \vec{p}_{A\,sys} - m\frac{\vec{p}_{A\,sys}}{m} = \vec{0}. \quad (6.22)$$

Equations 6.21 and 6.22 show that relative to Earth the velocity of the zero-momentum reference frame Z for a system of objects is equal to the system's momentum measured in the Earth reference frame divided by the inertia of the system (as we stated in Section 6.4):

$$\vec{v}_{EZ} = \frac{\vec{p}_{E\,sys}}{m} = \frac{m_1\vec{v}_{E1} + m_2\vec{v}_{E2} + \cdots}{m_1 + m_2 + \cdots} \quad \begin{matrix}\text{(zero-momentum} \\ \text{reference frame)}\end{matrix}. \quad (6.23)$$

The velocity of the zero-momentum reference frame is related to the position of the **center of mass** of a system. This position is defined as

$$\vec{r}_{cm} \equiv \frac{m_1\vec{r}_1 + m_2\vec{r}_2 + \cdots}{m_1 + m_2 + \cdots}, \quad (6.24)$$

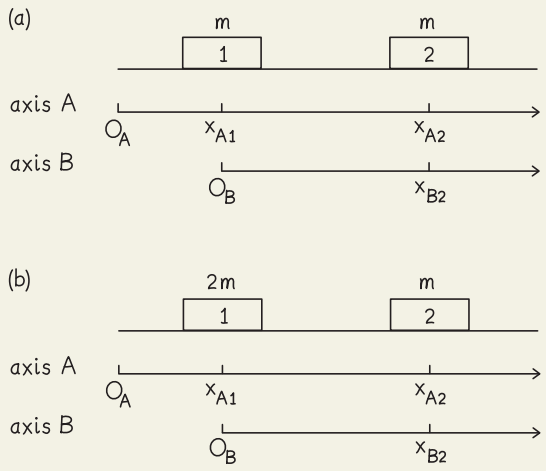
where $\vec{r}_1, \vec{r}_2, \ldots$ represent the positions of the objects of inertia $m_1, m_2, \ldots$ in the system.* Equation 6.24 applies to the values of the positions measured in *any* reference frame (and for this reason we can omit the reference-frame subscripts). To show the relationship between the velocity of the zero-momentum reference frame and the position of the center of mass, we take the derivative of the left and right sides of Eq. 6.24 with respect to time:

$$\frac{d\vec{r}_{cm}}{dt} = \frac{m_1(d\vec{r}_1/dt) + m_2(d\vec{r}_2/dt) + \cdots}{m_1 + m_2 + \cdots}. \quad (6.25)$$

*Even though I pointed out in Chapter 4 that *mass* and *inertia* are related and they are essentially synonyms, we should—to be consistent with our use of the word *inertia* for the quantity m—call $\vec{r}_{cm}$ the position of the *center of inertia*. Historically, however, $\vec{r}_{cm}$ has always been called the position of the *center of mass*, a tradition we shall follow.

Because $d\vec{r}/dt = \vec{v}$ (Eq. 2.25), we can rewrite Eq. 6.25 in the form

$$\vec{v}_{\text{cm}} \equiv \frac{d\vec{r}_{\text{cm}}}{dt} = \frac{m_1\vec{v}_1 + m_2\vec{v}_2 + \cdots}{m_1 + m_2 + \cdots}, \tag{6.26}$$



where $\vec{v}_{\text{cm}}$ is the system's **center-of-mass velocity.** Note that this velocity is precisely the velocity of the zero-momentum reference frame in Eq. 6.23. Thus we conclude that, when measured from a reference frame moving at the same velocity as the center of mass of a system, the system's momentum is automatically zero. (In other words, such a reference frame is a zero-momentum reference frame.) In figures we shall denote the center of mass by a circle with a cross in it: ⊗.

EXAMPLE 6.7 Two-cart center of mass

The positions of two identical carts at rest on a low-friction track are measured relative to two axes oriented in the same direction along the track. On axis A, cart 1 is at x_{A1} and cart 2 is at x_{A2}. On axis B, cart 1 is at the origin and cart 2 is at x_{B2}. (*a*) Determine the position of the center of mass of the two-cart system relative to each axis. (*b*) If instead of identical carts you have $m_1 = 2m_2$, what is the position of the center of mass on each axis?

❶ **GETTING STARTED** I begin by making a sketch of the situation (**Figure 6.16**). Each axis corresponds to a reference frame that is at rest relative to Earth. Because the origins of the two axes don't coincide, the x components of the cart positions on axis A are different from those on axis B. I have to use these x components to determine the position of the system's center of mass on each axis for two cases: when the cart inertias are identical and when they are not. (For simplicity, the carts are treated as points; the positions given are the positions of these points.)

Figure 6.16

❷ **DEVISE PLAN** The position of the center of mass of a system of objects is given by Eq. 6.24. To use this equation in this problem, I must write it in terms of components. For axis A, I have

$$x_{\text{Acm}} = \frac{m_1x_{\text{A1}} + m_2x_{\text{A2}}}{m_1 + m_2}, \tag{1}$$

and for axis B I replace the subscripts A with B. To solve this problem, I substitute the given values into this equation.

❸ **EXECUTE PLAN** (*a*) Substituting $m_1 = m_2 = m$ into Eq. 1, I get for axis A

$$x_{\text{Acm}} = \frac{mx_{\text{A1}} + mx_{\text{A2}}}{m + m} = \frac{m(x_{\text{A1}} + x_{\text{A2}})}{2m} = \frac{x_{\text{A1}} + x_{\text{A2}}}{2}. \checkmark$$

This position is halfway between the the two carts (see Figure 6.16). For axis B, I get

$$x_{\text{Bcm}} = \frac{mx_{\text{B1}} + mx_{\text{B2}}}{m + m} = \frac{m(0 + x_{\text{B2}})}{2m} = \frac{x_{\text{B2}}}{2}, \checkmark$$

which is again the position midway between the two carts.

(*b*) Now I have $m_1 = 2m_2 = 2m$, and so for axis A,

$$x_{\text{Acm}} = \frac{2mx_{\text{A1}} + mx_{\text{A2}}}{2m + m} = \frac{2x_{\text{A1}} + x_{\text{A2}}}{3}. \checkmark$$

This position is one-third of the way from x_{A1} to x_{A2} on axis A because $(2x_{\text{A1}} + x_{\text{A2}})/3 = x_{\text{A1}} + (x_{\text{A2}} - x_{\text{A1}})/3$. For axis B,

$$x_{\text{Bcm}} = \frac{2m \cdot (0) + mx_{\text{B2}}}{2m + m} = \frac{x_{\text{B2}}}{3}, \checkmark$$

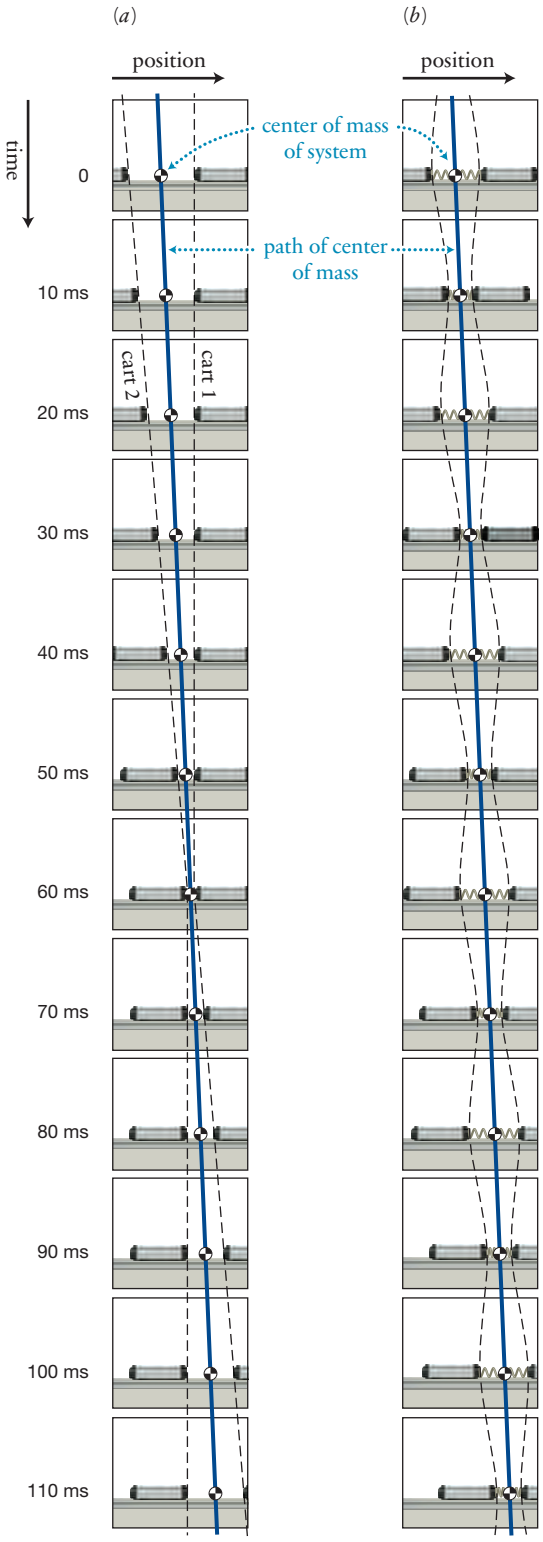
which is one-third of the way between the origin of axis B and cart 2. If you go back to the carts in Figure 6.16*b* and mark the center-of-mass position on both axes, you'll see that the position $x_{\text{Bcm}} = x_{\text{B2}}/3$ is aligned with the position $x_{\text{Acm}} = (2x_{\text{A1}} + x_{\text{A2}})/3$, as it must be. The center of mass of any given system can be at one position only, regardless of which reference frame is used to locate that position.

❹ **EVALUATE RESULT** When $m_1 = m_2$, the center of mass lies at the center of the system (midway between the carts) regardless of the choice of axis, which makes sense. When $m_1 = 2m_2$, the center of mass lies twice as close to cart 1 as to cart 2. This makes sense because I expect the center of mass to shift toward the object with the larger inertia. If, for example, the inertia of cart 1 were so large that the inertia of cart 2 was negligible, I could drop the second term in the numerator and denominator of Eq. 1, which would make the position of the center of mass be that of cart 1.

6.10 In Example 6.7, let $m_1 = 3m_2$. (*a*) Where on axis A is the center of mass of the two-cart system? (*b*) Where on axis A would you need to place a third cart of inertia $m_3 = m_1$ so that the center of mass of the three-cart system is at the position of cart 2?

Example 6.7 demonstrates an important point: The position of the center of mass of a system is a property of the system that is independent of the choice of reference frame. Equation 6.24 suggests that the center of mass represents a sort of "average" position of a system, but the center of mass is more important than that. Back in Chapter 2 we began our study of motion by specifying the position of an object at each instant by the position vector $\vec{r}$. Real objects, however, are *extended* rather than *point-like,* and so to say "the position" of a system or of a real object is not a precise statement unless we specify a fixed reference point in the system or on the object. For example, the statement "I parked my car 3 m from the fire hydrant" could mean that the front end of the car is 3 m away from the hydrant, or the midpoint of the car is 3 m from the hydrant, or any other point on the car is 3 m from the hydrant. The center of mass allows us to specify a fixed position in a system according to an exact prescription given by Eq. 6.24.

For extended objects, we can apply Eq. 6.24 by dividing the object into small pieces and substituting the position and inertia of each piece into the equation. This method is described in Appendix D. For symmetrical objects that have a uniformly distributed inertia, however, we don't need to carry out the calculation because the center of mass lies on an axis of symmetry and on any plane of symmetry. For example, the center of mass of a uniform rod lies at the center of the rod, midway between its ends, and the center of mass of a uniform sphere or cube lies at the geometric center of the sphere or cube.



Center of mass is also an important tool in our quest for simplification: It allows us to be precise even for systems where the motion is complex. To take a specific example, consider the motions shown in **Figure 6.17**. Because the two carts are identical, the center of mass of the two-cart system is always halfway between them. Notice that the center-of-mass motion is unaffected by the collision in Figure 6.17*a*. This is so because the momentum of the system doesn't change, and so the motion of the system must be constant. The center of mass of the system moves at velocity $\vec{v}_{\text{cm}}$ both before and after the collision.

The importance of the center of mass becomes even more evident in Figure 6.17*b*. Now the carts bounce back and forth because of the action of the spring while the two-cart system as a whole moves to the right. The motion of the center of mass of the system is entirely independent of the motion of the carts relative to each other and independent of the interactions between the carts. Even though the system continuously changes shape (the distance between the carts keeps changing), the center of mass provides a fixed reference point that moves at constant velocity.

6.11 (*a*) Determine the center-of-mass velocity of the two carts in Figure 6.8*a* before and after the collision, and verify that it is equal to the velocity of the carts at the point where the two $v_x(t)$ curves intersect. (*b*) Is the velocity of the carts at the point where the two $v_x(t)$ curves intersect always equal to the center-of-mass velocity? (*c*) Determine the velocities of the two carts in the zero-momentum reference frame, before and after the collision, and show that in this reference frame the momentum of the system is always zero.

QUANTITATIVE TOOLS

Figure 6.17 Two identical carts moving on a low-friction track. (*a*) The carts collide elastically. (*b*) The carts are connected by a spring and bounce back and forth about the center of mass. In both cases, the center of mass moves at constant velocity, so that the $x(t)$ curve for the center of mass is always a straight line.

6.7 Convertible kinetic energy

We can derive some additional useful expressions involving the center-of-mass velocity. Keeping in mind that $\vec{v}_{\text{Eo}} = \vec{v}_{\text{EZ}} + \vec{v}_{\text{Zo}}$ (Eq. 6.8) and that for the zero-momentum reference frame $\vec{v}_{\text{EZ}} = \vec{v}_{\text{cm}}$ (Eqs. 6.23 and 6.26), we can derive an expression that gives, for a system of objects, the kinetic energy $K_{\text{E sys}}$ measured in the Earth reference frame in terms of the corresponding kinetic energy $K_{\text{Z sys}}$ measured in the zero-momentum reference frame:

$$\begin{aligned} K_{\text{E sys}} &= \tfrac{1}{2}m_1 v_{\text{E1}x}^2 + \tfrac{1}{2}m_2 v_{\text{E2}x}^2 + \cdots \\ &= \tfrac{1}{2}m_1 (v_{\text{cm}x} + v_{\text{Z1}x})^2 + \tfrac{1}{2}m_2 (v_{\text{cm}x} + v_{\text{Z2}x})^2 + \cdots . \end{aligned} \tag{6.27}$$

Working out the first term on the right gives

$$\tfrac{1}{2}m_1 (v_{\text{cm}x} + v_{\text{Z1}x})^2 = \tfrac{1}{2}m_1 v_{\text{cm}}^2 + m_1 v_{\text{cm}x} v_{\text{Z1}x} + \tfrac{1}{2}m_1 v_{\text{Z1}}^2, \tag{6.28}$$

where I dropped the subscripts x on the terms that contain squares of the x component of the velocity because $v_x^2 = v^2$. Working out the other terms in Eq. 6.27 and gathering terms that contain equal powers of $v_{\text{cm}x}$, we obtain

$$\begin{aligned} K_{\text{E sys}} &= \tfrac{1}{2}(m_1 + m_2 + \cdots)v_{\text{cm}}^2 + (m_1 v_{\text{Z1}x} + m_2 v_{\text{Z2}x} + \cdots)v_{\text{cm}x} \\ &\quad + \left(\tfrac{1}{2}m_1 v_{\text{Z1}}^2 + \tfrac{1}{2}m_2 v_{\text{Z2}}^2 + \cdots\right). \end{aligned} \tag{6.29}$$

From the definition of the zero-momentum reference frame, we have

$$m_1 v_{\text{Z1}x} + m_2 v_{\text{Z2}x} + \cdots = p_{\text{Z1}x} + p_{\text{Z2}x} + \cdots = (p_{\text{Z sys}})_x = 0, \tag{6.30}$$

so that the middle term on the right in Eq. 6.29 disappears. The last term in Eq. 6.29 is the kinetic energy $K_{\text{Z sys}}$ of the system measured in the zero-momentum reference frame, and so substituting $m = m_1 + m_2 + \cdots$, we have

$$K_{\text{E sys}} = \tfrac{1}{2}mv_{\text{cm}}^2 + K_{\text{Z sys}}. \tag{6.31}$$

The first term on the right in this equation, called the system's **translational kinetic energy,** is the kinetic energy associated with the motion of the center of mass of the system:

$$K_{\text{cm}} \equiv \tfrac{1}{2}mv_{\text{cm}}^2. \tag{6.32}$$

This term has the form of the kinetic energy of an object of inertia m moving at speed v_{cm}.

For an isolated system, the translational kinetic energy K_{cm} is *nonconvertible*, which means that it cannot be converted to internal energy. To see why this is true, note that this kinetic energy is a function of the system's center-of-mass velocity, which cannot change for an isolated system (see Section 6.8).

The remainder of the kinetic energy—the $K_{\text{Z sys}}$ term in Eq. 6.31—is the system's **convertible kinetic energy,** the amount that can be converted to internal energy without changing the momentum of the system. It is equal to the system's kinetic energy minus the (nonconvertible) translational kinetic energy:

$$\begin{aligned} K_{\text{conv}} \equiv K_{\text{Z sys}} &= K_{\text{E sys}} - \tfrac{1}{2}mv_{\text{cm}}^2 \\ &= \left(\tfrac{1}{2}m_1 v_{\text{E1}}^2 + \tfrac{1}{2}m_2 v_{\text{E2}}^2 + \cdots\right) - \tfrac{1}{2}(m_1 + m_2 + \cdots)v_{\text{cm}}^2. \end{aligned} \tag{6.33}$$

With this last equation, we can eliminate any reference to the zero-momentum reference frame in Eq. 6.31, leaving only quantities measured in the Earth reference frame:

$$K_{\text{E sys}} = K_{\text{cm}} + K_{\text{conv}}. \tag{6.34}$$

If we had started not from an expression for the kinetic energy in the Earth reference frame (Eq. 6.27) but from the corresponding expression in any other inertial reference frame A, we would have obtained the same results, with A substituted for all the subscripts E. For this reason, we can omit the subscript E and rewrite Eqs. 6.31–6.34 in a form that holds in any inertial reference frame:

$$K = K_{\text{cm}} + K_{\text{conv}}, \tag{6.35}$$

where
$$K_{\text{conv}} = \left(\tfrac{1}{2}m_1v_1^2 + \tfrac{1}{2}m_2v_2^2 + \cdots\right) - \tfrac{1}{2}mv_{\text{cm}}^2. \tag{6.36}$$

The kinetic energy of a system can be split into a convertible part and a nonconvertible part. The nonconvertible part is the system's translational kinetic energy $K_{\text{cm}} = \frac{1}{2}mv_{\text{cm}}^2$. The remainder of the kinetic energy is convertible.

For a system of two colliding objects, the convertible kinetic energy is

$$K_{\text{conv}} = K - \tfrac{1}{2}mv_{\text{cm}}^2 = \left(\tfrac{1}{2}m_1v_1^2 + \tfrac{1}{2}m_2v_2^2\right) - \tfrac{1}{2}(m_1 + m_2)v_{\text{cm}}^2. \tag{6.37}$$

With some algebra (see Checkpoint 6.12), substituting the Eq. 6.26 form of v_{cm} into this expression yields

$$K_{\text{conv}} = \tfrac{1}{2}\left(\frac{m_1m_2}{m_1 + m_2}\right)v_{12}^2 \quad \text{(two-object system)}. \tag{6.38}$$

If I now write

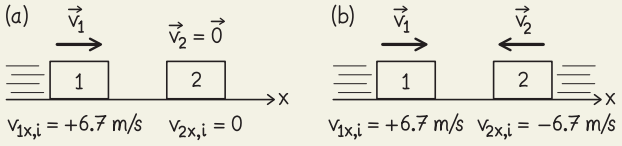
$$\mu \equiv \frac{m_1m_2}{m_1 + m_2}, \tag{6.39}$$

then the convertible kinetic energy for two objects takes the simple form

$$K_{\text{conv}} = \tfrac{1}{2}\mu v_{12}^2 \qquad \text{(two-object system)}, \tag{6.40}$$

where $\vec{v}_{12} = \vec{v}_2 - \vec{v}_1$ is the relative velocity of the two objects (see Eq. 5.1). The right side of this expression has the form of the kinetic energy of an object of inertia μ moving at a speed v_{12}. The quantity represented by the Greek letter μ (mu), which we introduced to simplify our notation, thus has the same units as inertia. It is called the **reduced inertia,** or *reduced mass*, because it is less than the inertia of either of the two colliding objects.

6.12 Verify that Eq. 6.38 is valid by substituting Eq. 6.26 for v_{cm} into Eq. 6.37 and working through the algebra.



EXAMPLE 6.8 Crash test

Two collisions are carried out to crash-test a 1000-kg car. (*a*) While moving at 15 mi/h, the car strikes an identical car initially at rest. (*b*) While moving at 15 mi/h, the car strikes an identical car moving toward it and also traveling at 15 mi/h. For each collision, how much kinetic energy can be converted to internal energy, and what fraction of the initial kinetic energy of the two-car system does this represent?

❶ **GETTING STARTED** I am given the inertias of two cars and their initial velocities in two collisions. I must calculate two values for each collision: the amount of kinetic energy converted during the collision and what fraction of the system's energy this converted amount is. I begin by making a sketch of the situation before each collision (**Figure 6.18**). I assume that the car that is initially at rest is free to roll (its parking brake is not on), and I ignore any friction so that I can consider the two-car system to be isolated. I also convert the speed from miles per hour to meters per second:

$$\frac{15 \text{ miles}}{1 \text{ hour}} \times \frac{1 \text{ hour}}{3600 \text{ s}} \times \frac{1609 \text{ m}}{1 \text{ mile}} = 6.7 \text{ m/s}.$$

Figure 6.18

❷ **DEVISE PLAN** The amount of energy that can be converted is given by Eq. 6.40, which requires me to calculate the reduced inertia of the two-car system (Eq. 6.39) and the relative speed of the two cars (Eq. 5.1). To determine the fraction of the initial kinetic energy that this converted amount of energy represents, I divide the converted amount by the sum of the initial kinetic energies $\frac{1}{2}mv^2$ of the two cars.

❸ **EXECUTE PLAN** (*a*) Substituting $m_1 = m_2 = 1000$ kg into Eq. 6.39, I obtain the reduced inertia of the two-car system: $\mu = 500$ kg. The initial relative speed of the two cars is

$$v_{12} = |v_{2x} - v_{1x}| = |0 - (+6.7 \text{ m/s})| = 6.7 \text{ m/s}$$

and so

$$K_{\text{conv}} = \tfrac{1}{2}(500 \text{ kg})(6.7 \text{ m/s})^2 = 11 \text{ kJ}. \checkmark$$

The initial kinetic energy of the system is $K_i = K_{1,i} = \frac{1}{2}(1000 \text{ kg})(6.7 \text{ m/s})^2 = 22$ kJ, and so the fraction of energy converted is $K_{\text{conv}}/K_i = (11 \text{ kJ})/(22 \text{ kJ}) = 0.50$. ✔

(*b*) The initial relative speed of the two cars is

$$v_{12} = |v_{2x} - v_{1x}| = |6.7 \text{ m/s} - (-6.7 \text{ m/s})| = 13.4 \text{ m/s}$$

and so $K_{\text{conv}} = \frac{1}{2}(500 \text{ kg})(13.4 \text{ m/s})^2 = 45$ kJ. ✔

The initial kinetic energy of the system is $K_i = K_{1,i} + K_{2,i} = \frac{1}{2}(1000 \text{ kg})(6.7 \text{ m/s})^2 + \frac{1}{2}(1000 \text{ kg})(6.7 \text{ m/s})^2 = 45$ kJ, and so all of the initial kinetic energy is convertible: $K_{\text{conv}}/K_i = (45 \text{ kJ})/(45 \text{ kJ}) = 1.0$. ✔

❹ **EVALUATE RESULT** When both cars move at 15 mi/h, the system has twice as much kinetic energy as when only one car moves at that speed, which makes sense. When only one car moves, however, the momentum of the system is nonzero, which means that not all the kinetic energy can be converted, as I found. In the second collision, the momentum of the system is zero, and so all of the kinetic energy can be converted, in agreement with my answer.

For an inelastic collision, v_{12} changes and so K changes, too. Using Eq. 6.35, we can write for the change in the kinetic energy of the system:

$$\Delta K = \Delta K_{\text{cm}} + \Delta K_{\text{conv}}. \tag{6.41}$$

The first term on the right is zero because the system is isolated, and so its translational kinetic energy cannot change. Substituting Eq. 6.40 into the last term, we have

$$\Delta K = \tfrac{1}{2}\mu v_{12f}^2 - \tfrac{1}{2}\mu v_{12i}^2 = \tfrac{1}{2}\mu(v_{12f}^2 - v_{12i}^2). \tag{6.42}$$

If we pull v_{12i}^2 out of the parentheses, we can write this expression in terms of the coefficient of restitution e (see Eq. 5.18):

$$\Delta K = \tfrac{1}{2}\mu v_{12i}^2\left(\frac{v_{12f}^2}{v_{12i}^2} - 1\right) = \tfrac{1}{2}\mu v_{12i}^2(e^2 - 1). \tag{6.43}$$

This value represents the amount of kinetic energy converted to internal energy during the inelastic collision. The maximum change in the system's kinetic energy occurs in a totally inelastic collision ($e = 0$):

$$\Delta K = -\tfrac{1}{2}\mu v_{12i}^2 \qquad \text{(totally inelastic collision)}. \tag{6.44}$$

So, when two colliding objects stick together, their relative velocity becomes zero and all of the convertible kinetic energy is converted to internal energy (compare Eqs. 6.40 and 6.44). Even though the collision is totally inelastic, however, the two-object system still has some kinetic energy because the nonconvertible part of the system's kinetic energy ($\frac{1}{2}mv_{\text{cm}}^2$) is unaffected by the collision.

For an elastic collision, $e = 1$, and so Eq. 6.43 becomes $\Delta K = 0$: The kinetic energy is the same before and after the collision, as expected.

6.13 A moving object that has inertia m strikes a stationary object that has inertia $0.5m$. (*a*) What fraction of the initial kinetic energy of the system is convertible? (*b*) Why can't the rest be converted?

6.8 Conservation laws and relativity

In Section 6.3 we introduced the principle of relativity, which states that the laws of the universe are the same in any inertial reference frame. In this section we prove this statement for the momentum and energy laws, which embody the laws of conservation of momentum and energy.

Let us consider a system from two reference frames, A and B, that are moving at velocity $\vec{v}_{\text{AB}}$ relative to each other. In Section 6.6 we saw that the momentum of an object is different in two reference frames that are moving relative to each other (Eq. 6.19), but now we are interested in *changes* in momentum. For an object of inertia m_{o}, we can write

$$\Delta\vec{p}_{\text{Ao}} = m_{\text{o}}\Delta\vec{v}_{\text{Ao}}. \tag{6.45}$$

Because a change in velocity in reference frame A is the same as a change in reference frame B (Eq. 6.10), we have

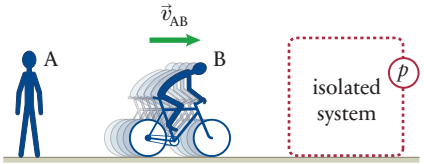
$$\Delta\vec{p}_{\text{Ao}} = m_{\text{o}}\Delta\vec{v}_{\text{Ao}} = m_{\text{o}}\Delta\vec{v}_{\text{Bo}} = \Delta\vec{p}_{\text{Bo}}, \tag{6.46}$$

which tells us that the change in momentum of an object is the same in reference frames A and B. So, for the momentum of a system of objects, we have

$$\Delta\vec{p}_{\text{A sys}} = \Delta\vec{p}_{\text{B sys}}. \tag{6.47}$$

In words, *changes in the momentum of a system are the same in any two reference frames moving at constant velocity relative to each other.*

Equation 6.47 tells us that if the change in momentum of a system is zero in reference frame A, then it is also zero in reference frame B. So, if a system is isolated in reference frame A, it is also isolated in reference frame B, as required by the principle of relativity (**Figure 6.19**).



Next we examine changes in the energy of a system. Let us first consider a change in the system's internal energy. In Section 5.3 we introduced internal energy as a quantitative measure of a change in state. Given that the state of any object or system cannot depend on the motion of the observer, we must conclude that any change in internal energy must be independent of the reference frame:

$$\Delta E_{\text{A int}} = \Delta E_{\text{B int}}. \tag{6.48}$$

Unfortunately, the situation is not so simple for a change in kinetic energy, as we saw in Section 6.3. If an object's velocity in reference frame A increases to $v_{\text{Ao}x,\text{i}} + \Delta v_{\text{Ao}x}$ from an initial value $v_{\text{Ao}x,\text{i}}$, its kinetic energy increases by an amount

$$\begin{aligned}\Delta K_{\text{Ao}} &= \tfrac{1}{2}m_{\text{o}}[(v_{\text{Ao}x,\text{i}} + \Delta v_{\text{Ao}x})^2 - (v_{\text{Ao}x,\text{i}})^2] \\ &= m_{\text{o}}v_{\text{Ao}x,\text{i}}\Delta v_{\text{Ao}x} + \tfrac{1}{2}m_{\text{o}}(\Delta v_{\text{Ao}x})^2.\end{aligned} \tag{6.49}$$

Figure 6.19 Whether or not a system is isolated does not depend on the motion of the observer, as long as the reference frames are inertial relative to each other.

Substituting Eqs. 6.8 and 6.10 into the right side, we get

$$\Delta K_{\mathrm{Ao}} = m_{\mathrm{o}}(v_{\mathrm{AB}x} + v_{\mathrm{Bo}x,\mathrm{i}})\Delta v_{\mathrm{Bo}x} + \tfrac{1}{2}m_{\mathrm{o}}(\Delta v_{\mathrm{Bo}x})^2. \tag{6.50}$$

Applying Eq. 6.49 to reference frame B, we have

$$\Delta K_{\mathrm{Bo}} = m_{\mathrm{o}}v_{\mathrm{Bo}x,\mathrm{i}}\Delta v_{\mathrm{Bo}x} + \tfrac{1}{2}m_{\mathrm{o}}(\Delta v_{\mathrm{Bo}x})^2. \tag{6.51}$$

When we expand Eq. 6.50, we get

$$\Delta K_{\mathrm{Ao}} = m_{\mathrm{o}}v_{\mathrm{AB}x}\Delta v_{\mathrm{Bo}x} + m_{\mathrm{o}}v_{\mathrm{Bo}x,\mathrm{i}}\Delta v_{\mathrm{Bo}x} + \tfrac{1}{2}m_{\mathrm{o}}(\Delta v_{\mathrm{Bo}x})^2. \tag{6.52}$$

Because the second and third terms on the right are exactly what we have on the right in Eq. 6.51, we see that

$$\Delta K_{\mathrm{Ao}} = m_{\mathrm{o}}v_{\mathrm{AB}x}\Delta v_{\mathrm{Bo}x} + \Delta K_{\mathrm{Bo}} \neq \Delta K_{\mathrm{Bo}} \qquad (\text{single object}), \tag{6.53}$$

which means that the change in an object's kinetic energy depends on the reference frame in which that change is measured.

To investigate whether or not ΔK, the change in the kinetic energy of a system made up of two colliding objects, is independent of the reference frame in which the energy is measured, let us examine the kinetic energy converted to internal energy, given by Eq. 6.42. In reference frame A we have

$$\Delta K_{\mathrm{A}} = \tfrac{1}{2}\mu(v_{A12,\mathrm{f}}^2 - v_{A12,\mathrm{i}}^2) \qquad (\text{two-object system}). \tag{6.54}$$

Because the relative velocities are *differences* in velocities, Eq. 6.10 tells us that $v_{\mathrm{B12}} = v_{\mathrm{A12}}$, and so the change in the system's kinetic energy must also be the same in any two inertial reference frames:

$$\Delta K_{\mathrm{B}} = \Delta K_{\mathrm{A}} \tag{6.55}$$

(in spite of the fact that the changes in kinetic energy are different for the individual objects!). Combining Eqs. 6.55 and 6.48 and generalizing the result to a system of more than two objects, we obtain

$$\Delta K_{\mathrm{B}} + \Delta E_{\mathrm{B\,int}} = \Delta K_{\mathrm{A}} + \Delta E_{\mathrm{A\,int}} \tag{6.56}$$

or

$$\Delta E_{\mathrm{A\,sys}} = \Delta E_{\mathrm{B\,sys}}. \tag{6.57}$$

In words, *changes in the energy of a system are the same in any two reference frames moving at constant velocity relative to each other*.

Equation 6.57 tells us that if the change in energy of a system is zero in reference frame A, then it is also zero in reference frame B. So, if a system is closed in reference frame A, it is also closed in reference frame B, as required by the principle of relativity.

QUANTITATIVE TOOLS

6.14 Objects 1 ($m_1 = 1.0$ kg) and 2 ($m_2 = 3.0$ kg) collide inelastically. The velocities are $v_{1x,\mathrm{i}} = +4.0$ m/s, $v_{2x,\mathrm{i}} = 0$, $v_{1x,\mathrm{f}} = -0.50$ m/s, and $v_{2x,\mathrm{f}} = +1.5$ m/s. (*a*) What is the coefficient of restitution e? (*b*) Make a table like Table 6.1 showing the kinetic energy converted to internal energy both in the Earth reference frame and in a reference frame moving at $v_{\mathrm{EM}x} = -1.0$ m/s relative to Earth.

Chapter Summary

Inertial reference frames (Sections 6.1–6.4, 6.6)

Concepts A **reference frame** is a combination of a reference axis that defines a direction in space and a reference point that defines the origin from which motion is measured. The **Earth reference frame** is a reference frame at rest relative to Earth.

An **inertial reference frame** is one in which the **law of inertia** holds, which means a reference frame in which an isolated object remains either at rest or in motion at constant velocity.

The **principle of relativity** states that the laws of the universe are the same in all inertial reference frames.

The **zero-momentum reference frame** for a system of objects is the reference frame in which the momentum of the system is zero. The velocity of this reference frame is equal to the velocity of the center of mass of the system.

Quantitative Tools The position $\vec{r}_{cm}$ of the **center of mass** of a system of objects of inertias $m_1, m_2, \ldots$ located at positions $\vec{r}_1, \vec{r}_2, \ldots$ is

$$\vec{r}_{cm} \equiv \frac{m_1\vec{r}_1 + m_2\vec{r}_2 + \cdots}{m_1 + m_2 + \cdots}. \tag{6.24}$$

The **center-of-mass velocity** of a system of objects is

$$\vec{v}_{cm} \equiv \frac{d\vec{r}_{cm}}{dt} = \frac{m_1\vec{v}_1 + m_2\vec{v}_2 + \cdots}{m_1 + m_2 + \cdots}. \tag{6.26}$$

This is also the velocity of the **zero-momentum reference frame** for this system.

Relative motion (Section 6.5)

Concepts The **Galilean transformation equations** allow us to transform quantities measured in one inertial reference frame into their values in another inertial reference frame when the two reference frames are moving at constant relative velocity. The transformation equations tell us that *time intervals*, *lengths*, and *accelerations* are the same in any two inertial reference frames moving at constant relative velocity.

Quantitative Tools The **Galilean transformation equations** relate the time t and position $\vec{r}_e$ for an event (e) measured in an inertial reference frame A to these quantities measured for the event in any other inertial reference frame B. If the reference frames have a constant relative velocity $\vec{v}_{AB}$ and have their origins coinciding at $t = 0$, the transformation equations are

$$t_B = t_A = t \tag{6.4}$$

and

$$\vec{r}_{Be} = \vec{r}_{Ae} - \vec{v}_{AB}t_e. \tag{6.5}$$

As a consequence of these equations, the velocity $\vec{v}_{Ao}$ of an object (o) measured in an inertial reference frame A is related to the object's velocity measured in any other inertial reference frame B by

$$\vec{v}_{Ao} = \vec{v}_{AB} + \vec{v}_{Bo}. \tag{6.14}$$

The transformation equations also give the relationship between accelerations measured in any two inertial reference frames A and B:

$$\vec{a}_{Ao} \equiv \vec{a}_{Bo}. \tag{6.11}$$

Convertible kinetic energy (Section 6.7)

Concepts The **translational kinetic energy** of a system is the kinetic energy associated with the motion of its center of mass. For an isolated system, this kinetic energy is **nonconvertible** because it cannot be converted to internal energy (if it were, the momentum of the system would not be constant).

The **convertible kinetic energy** of an isolated system is the portion of the

Quantitative Tools The **translational (nonconvertible) kinetic energy** K_{cm} of a system is

$$K_{cm} \equiv \tfrac{1}{2}mv_{cm}^2, \tag{6.32}$$

where m is the system's inertia and v_{cm} is the speed of its center of mass.

The **convertible kinetic energy** of a two-particle system is

$$K_{conv} = \tfrac{1}{2}\mu v_{12}^2, \tag{6.40}$$

system's kinetic energy that can be converted to internal energy. This energy is the same in all inertial reference frames.

The **kinetic energy** of a system can be split into a convertible part K_{conv} and a nonconvertible part. The nonconvertible part is the system's translational kinetic energy K_{cm}.

where μ is the **reduced inertia** (or *reduced mass*) of the system, given by

$$\mu \equiv \frac{m_1 m_2}{m_1 + m_2}. \tag{6.39}$$

The kinetic energy of a system is

$$K = K_{cm} + K_{conv}. \tag{6.35}$$

Conservation laws and relativity (Section 6.8)

Concepts Changes in the momentum and energy of a system are the same in any two inertial reference frames.

Quantitative Tools If A and B are any two reference frames moving at constant velocity relative to each other, then the changes in the momentum and energy of any system are

$$\Delta \vec{p}_{A\,sys} = \Delta \vec{p}_{B\,sys} \tag{6.47}$$

$$\Delta K_B + \Delta E_{B\,int} = \Delta K_A + \Delta E_{A\,int}. \tag{6.56}$$

Questions and Problems

For instructor-assigned homework, go to Mastering Physics

Dots indicate difficulty level of problems: • = *easy*, •• = *intermediate*, ••• = *hard*; CR = *context-rich problem.*

6.1 Relativity of motion

1. Moving sidewalks are commonplace at large airports, but you must use caution getting on and off them. What should you do to make the transition easy when stepping onto one of these sidewalks? When stepping off? •
2. A flying bug hits the helmet of a coasting bicyclist. (What kind of collision do you expect this to be?) Draw the momentum vectors for the bug and the bicyclist before and after the collision (*a*) in the reference frame in which the bug is initially at rest and (*b*) in the reference frame in which the bicyclist is initially at rest. •
3. The data in the table were recorded for two race cars, A and B, driving down a straight stretch of track. Determine the average velocity of car B as measured by an observer in car A. ••

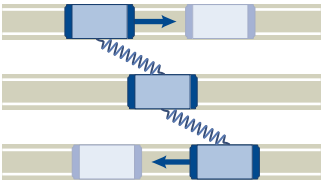
Time (s)	Car A position (m)	Car B position (m)
1	40	20
2	65	50
3	90	80
4	115	110
5	140	140
6	165	170
7	190	200
8	215	230
9	240	260
10	265	290

4. An observer in the Earth reference frame observes cart A and cart B moving toward each other with the same speed until they collide and come to rest. Consider this event as seen by observer A moving along with cart A. Assume that this observer matches cart A's initial velocity but does not collide with cart B (that is, observer A continues along at the same velocity that cart A had initially). Would the observer in the Earth reference frame and observer A obtain the same value for (*a*) the initial velocity of cart A, (*b*) the final velocity of cart B after the collision, and (*c*) the relative velocity of the two carts after the collision? ••
5. As you are standing on the platform, a boy in a train moving to the right extends his hand outside the window and releases a ball. In what direction is the ball moving according to (*a*) you, and (*b*) the boy? Ignore air resistance. ••
6. Two objects, A and B, of equal inertia approach each other with relative velocity $\vec{v}_{AB}$ and collide elastically. For each object, draw a velocity-versus-time graph for the interval starting a few seconds before the collision and ending a few seconds after the collision (*a*) from the reference frame in which A is initially at rest, (*b*) from the reference frame in which B is initially at rest, and (*c*) from the zero-momentum reference frame. ••

6.2 Inertial reference frames

7. You are watching a race while sitting on a bench. An athlete speeds up from 0 to 7 m/s to the right. Describe his motion from the point of view of another athlete going at (*a*) 5 m/s to the right, (*b*) 5 m/s to the left, and (*c*) accelerating from 0 to 5m/s to the right. •

8. On a long bus ride, you walk from your seat to the back of the bus to use the restroom. If the bus is driving at 100 km/h, and you walk at 2.0 m/s from your seat to the restroom, how quickly are you moving relative to the ground? •
9. A pickup truck has several empty soda cans loose in the bed. Why do the cans roll forward in the bed when the truck slows down? •
10. Does a man standing in an elevator that is moving upward at a constant speed of 10 m/s feel heavier or lighter? What if the elevator is moving downward at the same speed? If the elevator slows down to a stop? ••
11. Train A, $m_A = 150{,}000$ kg, is traveling west at 60 km/h. Train B, $m_B = 100{,}000$ kg, behind train A on the same track, is traveling west at 88 km/h and so is gaining on train A. Because the engineer driving B fails to slow down, B runs into the back of A. The two trains stick together and then move as a single unit after the collision. What is the momentum of each train before the collision and after the collision according to (*a*) an observer standing alongside the tracks and (*b*) an observer in a westbound automobile traveling at 100 km/h on a road that parallels the tracks? ••
12. A 1000-kg car traveling east at 50 km/h passes over the top of a hill and hits a 3000-kg truck stalled in the middle of the lane. The impact causes the truck to roll eastward at 15 km/h. (*a*) What is the coefficient of restitution for the collision? During the collision, how much kinetic energy is converted to internal energy (*b*) in the Earth reference frame and (*c*) in a reference frame moving at 5 km/h eastward along the road? ••
13. You are riding a 450-kg horse at 14.4 km/h east along a desert road. You have inertia equal to 60.0 kg. A police officer driving past (whom you know and who knows your inertia and the horse's inertia) measures your speed relative to the police car and calculates your kinetic energy to be 16.32 kJ. What possible speed(s) could the police car have been driving at the instant the officer measured your speed? •••



6.3 Principle of relativity

14. Two cars collide head-on on a busy street. An observer standing on the street witnesses the accident and calculates how much of the cars' initial kinetic energy went into deforming the cars upon collision, E_{def}. A police officer was driving next to one of the cars at a matching speed when the cars collided. Would this officer calculate a higher value of E_{def}, a lower value of E_{def}, or the same value of E_{def} if he used the velocities of the cars measured in his reference frame? •
15. A horizontal escalator connecting airport terminals is 1 km long. Two kids start from opposite ends and run toward each other at 3 m/s and meet 600 m from the start of the escalator. What is the speed of the escalator? How long do they take to reach each other? •
16. Do the laws of the universe change if the clocks in two inertial reference frames, A and B, are not synchronized (in other words, if $t_A = t_B + \Delta\tau$, where $\Delta\tau$ is some constant time interval)? ••
17. You place a 0.10-kg sonic ranger on a low-friction track in front of a 0.50-kg cart to measure the cart's velocity in the Earth reference frame, which turns out to be $+(1.0\ \text{m/s})\,\hat{\imath}$. You are distracted, the cart hits the ranger in a totally inelastic collision, and the two objects then move forward together. A friend is running toward the cart with a velocity of $-(3.0\ \text{m/s})\,\hat{\imath}$ with her sonic ranger on and pointed at the cart. (*a*) What is the momentum of the cart, with the ranger stuck to it, in your friend's reference frame? (*b*) What velocity does her sonic ranger measure for the cart after the collision? ••
18. At the roller rink, two 20-kg girls accelerate toward each other until they are each moving at 2.0 m/s in the Earth reference frame. They then collide stomach-to-stomach, grab on to each other, and fall to the floor. Calculate the momentum of each girl before the collision and after the collision (*a*) in the Earth reference frame and (*b*) in the reference frame of a mother who started skating with one of the girls and then continued on after the collision without changing speed. (*c*) The fathers decide the collision looks like fun and give it a try. Explain, in terms of energy, why they don't enjoy it nearly as much as their daughters do. ••
19. Carts A and B are identical and are moving toward each other on a track. The speed of cart A is v, while the speed of cart B is $2v$. In the Earth reference frame, the system of the two carts has kinetic energy K. Is there any other reference frame in which the two-cart system has the same kinetic energy K? If so, describe this reference frame. Otherwise, explain why no such reference frame exists. •••

6.4 Zero-momentum reference frame

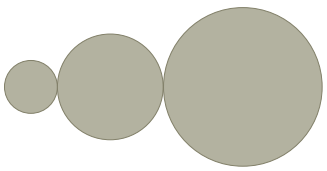
20. Two identical cars approach each other head-on while traveling at the same speed. What does an observer in the Earth reference frame measure for the speed of the zero-momentum reference frame of this two-car system? Suppose the same cars are traveling in the same direction. Now what does an observer in the Earth reference frame measure for the speed of the zero-momentum reference frame? •
21. Two identical particles of inertia m collide elastically on a low-friction table. Calculate the kinetic energy of the system before and after the collision in the zero-momentum frames. •
22. Two identical particles, A and B, collide elastically. In the zero-momentum reference frame, what can you say about the ratios of the final and initial speeds, $v_{A,f}/v_{A,i}$ and $v_{B,f}/v_{B,i}$? •
23. Figure P6.23 shows three identical carts placed on rails (so that they can slide easily left and right) and connected to one another by springs. There are two simple, symmetrical ways for this system to vibrate in the zero-momentum reference frame. One way is the sweeping-X pattern shown in the figure. Draw the other way. ••

Figure P6.23

24. Two objects A and B having inertias $m_a = m$ and $m_b = 3m$ are moving with velocities $v_a = v$ and $v_b = 3v$. Find the velocities of the two objects in the zero-momentum frame of reference. ••
25. A 4000-kg dump truck is parked on a hill. The parking brake fails, and the truck rolls down the hill. It then coasts briefly along a horizontal stretch of road at 36 km/h before hitting a stationary 1000-kg car. The car sticks to the grill of the truck, and the two vehicles continue moving forward. (*a*) What is the speed of the combined unit immediately after the collision? (*b*) What is the momentum of the combined unit in the reference frame of a jogger approaching the collision at 2.0 m/s and moving in the direction opposite the direction of the velocity of the moving unit? (*c*) How fast, and in which direction, must the jogger be running in order for the momentum of the combined unit to be zero in his reference frame? ••
26. In the Earth reference frame, box 1 is approaching box 2, which is initially at rest on a low-friction floor, with velocity v. Box 1 has five times the inertia of box 2. They collide elastically. Calculate the velocities before and after collision in (*a*) the Earth reference frame and (*b*) the zero-momentum reference frame. •••
27. In an elastic collision between a lightweight object and a heavy object, which one carries away more of the kinetic energy? Does the answer depend on the initial speeds? (Hint: Begin with the zero-momentum reference frame for clarity.) •••

6.5 Galilean relativity

28. When two identical objects traveling at the same speed collide head-on, an observer standing in the Earth reference frame sees both objects changing direction. Do observers in every inertial reference frame that is moving relative to the Earth reference frame also see both objects changing direction? •
29. You toss a ball into the air and note the time interval between the ball leaving your hand and reaching its greatest height above you. While you are doing this, a construction worker being lifted on a hydraulic platform at constant speed also notes the time interval needed for the ball to reach its greatest height relative to himself. Is the time interval reported by the worker *longer, shorter,* or *the same as* the interval you report? ••
30. A student runs an experiment with two carts on a low-friction track. As measured in the Earth reference frame, cart 1 ($m = 0.36$ kg) moves from left to right at 1.0 m/s as the student walks along next to it at the same velocity. (*a*) What velocity $\vec{v}_{E2,i}$ in the Earth reference frame must cart 2 ($m = 0.12$ kg) have before the collision if, in the student's reference frame, cart 2 comes to rest right after the collision and cart 1 reverses direction and travels from right to left at 0.33 m/s? (*b*) What does the student measure for the momentum of the two-cart system? (*c*) What does a person standing in the Earth reference frame measure for the momentum of each cart before the collision? ••
31. Notice that in Figure 6.12 the time intervals of the interaction are all the same, regardless of the reference frame shown. Is this true in all reference frames? Why or why not? ••
32. In a three-car crash, car A bumps into the back end of car B, which then goes forward and bumps into the back end of car C. Is the distance that car B moves between the collisions the same in all inertial reference frames? ••
33. Riding up an escalator while staying on the same step for the whole ride takes 30 s. Walking up the same escalator takes 20 s. How long does it take to walk down the up escalator? ••
34. You run at 4 m/s in the same direction as a river flowing at 2 m/s. This speed is enough to keep you chatting with your friend who is steering a slow boat on the river. How fast is your friend going? How fast should your friend go, and in what direction, if the river suddenly speeds up to 3 m/s? ••
35. Airline pilots who fly round trips know that their round-trip travel time increases if there is any wind. To see this, suppose that an airliner cruises at speed v relative to the air. (*a*) For a flight whose one-way distance is d, write an expression for the interval Δt_{calm} needed for a round trip on a windless day. Ignore any time spent on the ground, and assume that the airliner flies at cruising speed for essentially the whole trip. (*b*) Now assume there is a wind of speed w. It doesn't matter which way the wind is blowing; all that matters is that it is a head wind in one direction and a tail wind in the opposite direction. Write an expression for the time interval Δt_{wind} needed for a round trip on the day this wind is blowing. Then show that your expression reduces to



$$\Delta t_{\text{wind}} \approx \Delta t_{\text{calm}}\left[1 + \left(\frac{w}{v}\right)^2\right]$$

provided that $w \ll v$. (For the last step, you may need to know that $(1 \pm z)^b \approx 1 \pm bz$ when $z \ll 1$.) •••

6.6 Center of mass

36. The inertia of an object is m measured when the object is at rest in the Earth reference frame. According to Galilean relativity, what is its inertia measured by an observer moving past the object with a constant velocity $\vec{v}$ in the positive x direction? What is the object's momentum according to this observer? •
37. Jupiter, with an inertia 317.83 times that of Earth, is at an average distance of 7.784×10^{11} m from the Sun. At what distance from the centre of the Sun is the center of mass of the Sun-Jupiter system if the Sun's inertia is 333,000 times that of Earth, and its mean equatorial diameter is $\approx 1.392 \times 10^9$ m? •
38. Figure P6.38 shows three solid spheres of radii a, $2a$, and $3a$ made of materials with densities ρ, 2ρ, and 3ρ. Find the position of the center of mass of the system. ••

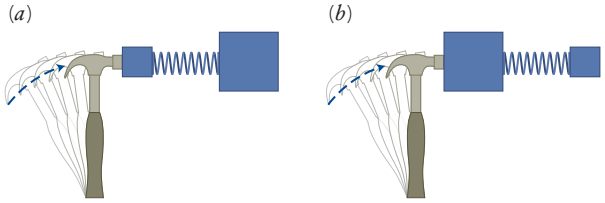


Figure P6.38

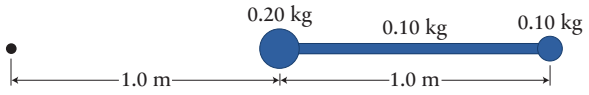
39. A boy and a girl are resting on separate rafts 10 m apart in calm water when the girl notices a small beach toy floating midway between the rafts. The girl and her raft have twice the inertia of the boy and his raft. The rafts are connected by a rope 12 m long, so she decides to pull on the rope, drawing the rafts together until she can reach the toy. Which raft gets to the toy first? How much distance is there between the two rafts when the first one reaches the toy? (Ignore the widths of the rafts.) ••

40. The two cubes in Figure P6.40 have different inertias. The cubes are connected to each other by a spring, and a hammer strikes them in the two ways, (*a*) and (*b*), shown in the figure. Assuming that the same impulse is transferred from the hammer, does the center-of-mass motion after the collision depend on which cube is struck first? ••

Figure P6.40

41. Determine the position of the center of mass of the baton shown in Figure P6.41, taking the origin of your coordinate axis to be (*a*) the center of the larger ball, (*b*) the center of the smaller ball, and (*c*) a point 1.0 m to the left of the larger ball. How much calculation was required for each of the three parts of this problem? ••

Figure P6.41



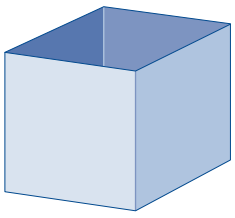


Figure P6.42

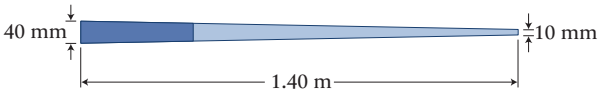


42. The empty cubical box shown in Figure P6.42 has no top face; that is, the box is made up of only five square faces. If all five faces have the same inertia, at what height above the bottom of the box is the center of mass? ••

43. How can you tell from the motion of the center of mass of an isolated system whether the reference frame from which the motion is measured is inertial? ••

44. Determine the center of mass of a pool cue whose diameter decreases smoothly from 40 mm to 10 mm over its 1.40-m length (Figure P6.44). Assume that the cue is made from solid wood, with no hidden weights inside. (Hint: See Appendix D for the center-of-mass computation for extended objects. You will find it easier to do the integral for a complete cone. The pool cue is a truncated cone—that is, a cone with its conical tip removed. Slicing off a piece is like adding negative inertia.) •••

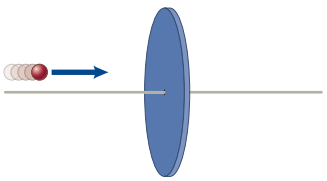
Figure P6.44

6.7 Convertible kinetic energy

45. A bullet of speed v and inertia m strikes and gets embedded in a wooden block of inertia M, initially at rest on a low-friction floor. Plot k_f/k_i as a function of M/m from $M/m = 0$ to $M/m = 10$, and discuss your result. •

46. A 3.0-g particle is moving toward a stationary 7.0-g particle at 3.0 m/s. What percentage of the original kinetic energy is convertible to internal energy? •

47. Think of a system of two objects of different inertias $m_1 < m_2$. How much larger than m_1 can the reduced inertia μ of the pair be? How much smaller than m_1 can it be? •



48. (*a*) Is there a reference frame in which the kinetic energy of a system is a minimum? If so, what is this reference frame? (*b*) Is there a reference frame in which the kinetic energy of a system is a maximum? If so, what is this reference frame? ••

49. You hit a pitched baseball with a bat. In which reference frame is the translational (nonconvertible) kinetic energy greater: the reference frame in which the bat is at rest immediately before the collision or the reference frame in which the ball is at rest immediately before the collision? ••

50. What is the ratio K_1/K_2 when K_1 is the kinetic energy converted to internal energy when two cars each initially traveling at 88 km/h collide head-on and K_2 is the kinetic energy converted to internal energy when a car moving at 88 km/h hits a stationary car? Assume that both cars have the same inertia and that the collisions are totally inelastic. (Hint: Determine how much of the energy is required to move the center of mass in each case.) ••

51. A 0.075-kg disk initially at rest in the Earth reference frame is free to move parallel to a horizontal bar through a hole at the disk's center. The disk is struck face-on by a 0.050-kg paintball traveling at 11 m/s, as illustrated in Figure P6.51. (*a*) What is the initial relative velocity of the disk and the paintball? (*b*) What is their reduced inertia? (*c*) If all the paint stays on the disk, what percentage of the original kinetic energy is converted to internal energy? (*d*) What is the change in kinetic energy measured by someone riding a bicycle at the velocity of the paintball before the collision? (*e*) Confirm your answer to part *d* by calculating the final and initial kinetic energies in the cyclist's reference frame. ••

Figure P6.51

52. Take the common case where a moving object of inertia m_{moving} collides with a stationary object of inertia m_{rest}. (*a*) Show that the fraction of kinetic energy not convertible in the collision is $m_{\text{moving}}/(m_{\text{moving}} + m_{\text{rest}})$. Interpret for the case where $m_{\text{rest}} \gg m_{\text{moving}}$ and for the case where $m_{\text{rest}} \ll m_{\text{moving}}$. (*b*) Does the value of the fraction depend on the elasticity of the collision? (*c*) Why is this energy not convertible? ●●

53. Ball 1 is moving toward you at 10 m/s, and you decide to throw ball 2 at it to make it reverse its velocity. The balls collide head-on, and the coefficient of restitution for the collision is 0.90. (*a*) If ball 1 has an inertia of 0.500 kg and ball 2 has an inertia of 0.600 kg, how fast must ball 2 be traveling in order to reverse the velocity of ball 1? (*b*) What is the initial relative velocity of the two balls? (*c*) What is their reduced inertia? (*d*) What percentage of the original kinetic energy is convertible? (*e*) What are the velocities of the two balls immediately after the collision? ●●

54. Ball 1 from Problem 53 is moving away from you at 5.0 m/s, and you decide to throw ball 2 at it to make it go faster. Once again the balls collide head-on, and the coefficient of restitution for the collision is 0.90. (*a*) Given the inertias in Problem 53, how fast must ball 2 be traveling in order to double the velocity of ball 1? (*b*) What is the initial relative velocity of the two balls? (*c*) What is their reduced inertia? (*d*) What percentage of the original kinetic energy is convertible? (*e*) What are the final velocities of the two balls immediately after the collision? ●●

55. If the relative velocities are the same in both cases, which has more convertible kinetic energy: a collision between two objects each of inertia m or a collision between an object of inertia m_1 and an object of inertia $m_2 < m_1$ with $m_1 + m_2 = 2m$? ●●

56. After coming down a slope, a 60-kg skier is coasting northward on a level, snowy surface at a constant 15 m/s. Her 5.0-kg cat, initially running southward at 3.8 m/s, leaps into her arms, and she catches it. (*a*) Determine the amount of kinetic energy converted to internal energy in the Earth reference frame. (*b*) What is the velocity, measured in the Earth reference frame, of an inertial reference frame in which the cat's kinetic energy does not change? ●●

57. You toss a 0.40-kg ball at 9.0 m/s to a 14-kg dog standing on an iced-over pond. The dog catches the ball and begins to slide on the ice. (*a*) Measured from the Earth reference frame, what is the velocity of the dog immediately after he catches the ball? (*b*) Measured from the Earth reference frame, what is the velocity of an inertial reference frame in which the ball's kinetic energy does not change? (*c*) Measured from the Earth reference frame, how much of the original kinetic energy of the system is convertible? (*d*) Measured from the reference frame described in part *b*, how much of the original kinetic energy of the system is convertible? ●●

58. Instead of defining a reduced inertia μ to characterize the convertible kinetic energy of a system, we could define a *reduced velocity* v_{red} as follows: For a system of two particles, one of inertia m_1 and velocity v_1 and the other of inertia m_2 and velocity v_2, the kinetic energy is

$$K = K_{\text{cm}} + K_{\text{conv}} = \tfrac{1}{2}(m_1 + m_2)v_{\text{cm}}^2 + \tfrac{1}{2}(m_1 + m_2)v_{\text{red}}^2.$$

Derive an expression for the reduced velocity in terms of the given variables. (Just as the center-of-mass velocity is a weighted mean of the individual velocities, the reduced velocity is a weighted difference between the individual velocities.) ●●●

6.8 Conservation laws and relativity

59. In this chapter you learned about the zero-momentum reference frame. You may be curious whether there is such a thing as a zero-energy reference frame. Does a zero-kinetic energy reference frame always exist, never exist, or sometimes exist? ●

60. After a totally inelastic collision, the kinetic energy of an isolated system composed of two objects is zero. What was the momentum of the system in the same reference frame before the collision? ●

61. A mother penguin and her chick are on a flat, icy surface. The mother is lying at rest 0.50 m from the edge of the water. The chick, which has one-fourth of its mother's inertia, is sliding, collides with her inelastically, and bounces back at one-eighth of its original speed. The mother wakes up as she hits the water 0.40 s later. (*a*) How fast was the chick going when it hit her? (*b*) To a penguin paddling directly toward them at 1.0 m/s, what is the mother's momentum before and after the collision in terms of m_{mother}? ●●

62. A 50-kg ice skater moves across the ice at a constant speed of 2.0 m/s. She is caught by her 70-kg partner, and then the pair continues to glide together. He is at rest when he catches her, and immediately afterward they both coast. (*a*) What is their velocity just after the catch? (*b*) A skater follows the girl at a constant speed of 1.0 m/s. What is the girl's change in momentum in the reference frame of the skater? ●●

63. In an inertial reference frame F, an orange of inertia m_{orange} and velocity $\vec{v}_{\text{orange}}$ collides totally inelastically with an apple of inertia m_{apple} initially at rest. (*a*) When this collision is viewed from an inertial reference frame G, the kinetic energy of the orange is unchanged by the collision. What does an observer in the F reference frame measure for the velocity of the G reference frame? (*b*) For the case where $m_{\text{orange}} = m_{\text{apple}}$, sketch the velocity vectors of the two objects in each reference frame before and after the collision. ●●

64. An 800-kg car moving at 108 km/hr hits and gets entangled with a large truck of inertia 10,000 kg initially at rest. What is the kinetic energy of the wreckage? How much energy is lost from the system? ●●

65. A 0.20-kg softball is traveling at a velocity of 20 m/s to the east relative to Earth. It collides head-on with a 0.40-kg rubber ball traveling at a velocity of 10 m/s to the west. (*a*) If the system's kinetic energy, as measured from the Earth reference frame, decreases by 20% because of the collision, what are the final velocities of the balls? (*b*) What change in internal energy has occurred? (*c*) An observer watches this collision from a reference frame moving at a velocity of 15 m/s to the east relative to the Earth reference frame. What changes in kinetic and internal energies does this observer measure? (*d*) What

changes in kinetic and internal energies would be measured by an observer in a reference frame traveling at 20 m/s east relative to the Earth reference frame? ●●

66. Derive an expression showing that when an elastic collision between two objects is viewed from the zero-momentum reference frame, the direction of the momentum of each object is reversed and the magnitude of the change in momentum of each object is twice the magnitude of that object's initial momentum. ●●●

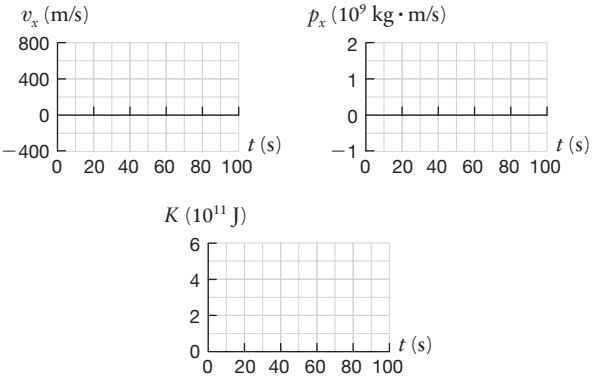
Additional Problems

67. Just as a car passes a school crossing guard, a child throws a toy from the back seat of the car toward his sister in the front seat. The toy is thrown at a speed of 2.0 m/s relative to the car, and the car is traveling at 10 m/s relative to Earth. Draw the velocity vectors for the toy, the car, and the crossing guard from the reference frame of (*a*) the car, (*b*) the guard, and (*c*) the toy. ●

68. A 15-kg box is pushed at 5 m/s across a low-friction floor and is caught by a 60-kg man on low-friction skates, initially at rest. What is the resulting kinetic energy of the man? How much energy is convertible? ●

69. A 72-kg woman is walking at 1.5 m/s. An 8-kg dog is running at six times that speed in the same direction. At what speed and in what direction relative to the woman would you have to be jogging in order for the dog to have the same momentum as the woman in your reference frame? ●

70. One rider is in a descending elevator that is accelerating to a stop. Another is in an elevator that is accelerating upward from rest. With their eyes closed, can the riders tell which of the two elevators they are in? ●●



71. You are in a noninertial reference frame observing two isolated objects of inertias m_1 and m_2 that move at constant speed relative to each other. What can you say about each object's (*a*) apparent acceleration and (*b*) apparent change in momentum? ●●

72. A bug of inertia m_B collides with the windshield of a Mack truck of inertia $m_T \gg m_B$ at an instant when the relative speed of the two is v_{BT}. (*a*) Express the system momentum in the truck's reference frame, then transform that expression to the bug's reference frame, and in so doing remove $m_B v_{BT}$ from the expression. (Remember, in the bug's reference frame, the bug is initially at rest and the truck is moving.) (*b*) Now express the system momentum in the bug's reference frame, then transform that expression to the truck's reference frame, and in so doing remove $m_T v_{BT}$ from the expression. (*c*) Is there something wrong here? How can we change the momentum by a small amount $m_B v_{BT}$ doing the transformation one way and by a large amount $m_T v_{BT}$ doing the transformation the other way? ●●

73. A 0.045-kg golf ball moving at 50 m/s (measured in the Earth reference frame) collides inelastically with a 1.8-kg, heavy-duty plastic flowerpot sitting on a windowsill. The coefficient of restitution for the collision is 0.50. Calculate the final velocities of the ball and the pot. Do this problem by first transforming to the zero-momentum reference frame, where the collision is much simpler, and then transforming back to the Earth reference frame. (Assume that all the action happens in one dimension and that the friction between pot and sill is insignificant.) ●●

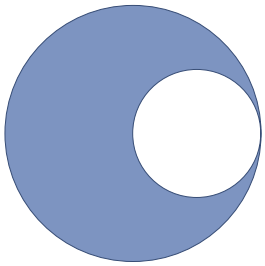
74. Asteroid A1, $m_{A1} = 3.60 \times 10^6$ kg, and asteroid A2, $m_{A2} = 1.20 \times 10^6$ kg, collide head-on in space. Approximate (rather poorly) the collision as being elastic. Observers watch the event from two space platforms. An observer on platform Q measures the speed of A1 to be 528 m/s and the speed of A2 to be 315 m/s, and sees A2 heading directly toward A1. The second platform, platform Z, is at rest in the zero-momentum reference frame of the asteroids. (*a*) What is the combined momentum of the asteroids measured from platform Q? (*b*) What is the velocity of platform Z relative to platform Q? (*c*) Draw velocity, momentum, and kinetic energy graphs for the asteroids as viewed from platform Z, using graphs like those in Figure P6.74. Assume the collision begins at $t = 40$ s and lasts for 20 s. (*d*) Add a curve for the momentum of the system to the momentum graph you constructed in part *c*. (*e*) What happens to the kinetic energy when its curve bends? (*f*) On your kinetic energy graph from part *c*, show what an observer on platform Z sees for the convertible and nonconvertible kinetic energies of the asteroids. (*g*) Repeat parts *c*–*f* as seen from platform Q. ●●

Figure P6.74

75. Assume that the asteroids in Problem 74 collide totally inelastically. Answer the same questions posed in that problem for this situation. ●●

76. A 1500-kg van is coasting to a stoplight at 15 m/s. A 1000-kg car behind the van is doing the same thing at 25 m/s and crashes into the rear of the van. The bumpers collide with a coefficient of restitution of 0.70. (*a*) What are the final velocities of the two vehicles? (*b*) How much kinetic energy is converted to internal energy in this collision? (*c*) How much energy is converted if the bumpers lock together in a totally inelastic collision? ●●

77. A 0.30-kg cart traveling along a low-friction track at 2.0 m/s relative to Earth collides with a 0.50-kg cart traveling in the same direction at 1.0 m/s relative to Earth. If the system's kinetic energy measured in the Earth reference frame increases by 30% as a result of the explosive collision, what are the final velocities of the carts in this reference frame? ●●



78. The transformation between position and time measurements in an inertial reference frame I and position and time measurements in a constantly accelerating (noninertial) reference frame N is given by

$$t_N = t_I = t$$
$$\vec{r}_N = \vec{r}_I - \vec{v}_{IN}t - \tfrac{1}{2}\vec{a}_{IN}t^2,$$

where $\vec{v}_{IN}$ is the velocity of the noninertial reference frame at $t = 0$ measured from the inertial reference frame and $\vec{a}_{IN}$ is the acceleration of the noninertial reference frame measured from the inertial reference frame. Derive by differentiation the transformation laws, giving v_N and a_N in terms of v_I and a_I. ●●●

79. The medallion shown in Figure P6.79 has been made by cutting a small circular piece out of a larger circular disk. The diameter of the original disk is twice the diameter of the hole, and the thickness of the disk is uniform. You begin to wonder about the location of the center of mass of this object, but the calculation seems impossibly difficult. Then you visualize two circular pieces coming together in superposition. Where is the center of mass? ●●● CR

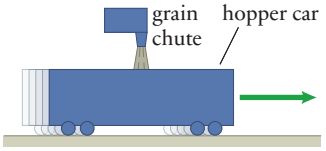


Figure P6.79

80. As an avid biker, you've come to realize that your top speed is really an air speed, not a ground speed, because air resistance is very noticeable when you ride fast. You like to ride at top speed for exactly an hour every day, and you know that on a calm day, you can ride 20 km before having to turn around and come back the same way. Today, though, you have a 20-km/h head wind for the first leg of the trip (which of course is a tailwind on the way back). You must be back home in an hour, so you look at your map. What top speed can you achieve today? ●●● CR

81. An uncoupled 20,000-kg railroad hopper car coasts along a track at 2.0 m/s. As it passes a grain chute, the chute opens (Figure P6.81), grain fills the car at a rate of 4000 kg/s for 5.0 s, and the chute closes. (*a*) How fast is the car going after the chute closes? (*b*) How far does the car travel during the 5.0 s in which grain is being added? (This distance is the length of the trail of grain in the car.) (*c*) Where is the center of mass of the grain-car system at the end of the 5.0 s? (*d*) Where is the center of mass of the trail of grain at the end of the 5.0 s? (*e*) Why doesn't the center of mass of the trail of grain coincide with the point midway between the two ends of the trail? ●●●

Figure P6.81

82. A skateboarder coasting at 5.0 m/s decides to coast into a friend going 4.0 m/s on rollerblades in the same direction. Unfortunately, the rollerblader stops right before the collision, too quickly for the skateboarder to react. The rollerblader turns around as he stops and pushes his arms out to ward off the collision. The rollerblader and his gear have a combined inertia of 70 kg, and the skateboarder and his gear have a combined inertia of 79 kg. (*a*) If the skateboarder ends up moving backward at 2.0 m/s, what is the coefficient of restitution for the collision? (*b*) What are the changes in kinetic and internal energies measured by an observer standing alongside the collision? (*c*) What are the changes in kinetic and internal energies measured by an observer in the zero-momentum reference frame for the skateboarder-rollerblader system? (*d*) If the rollerblader had not turned around and stopped, so that the skateboarder was able to grab him and keep coasting, what amount of kinetic energy would have been lost in the collision? ●●●

CONCEPTS

QUANTITATIVE TOOLS

In past chapters we saw how interactions can change the kinetic energy of objects as well as their internal energy. Every event that happens in this universe is the result of some interaction between objects. Interactions determine the structure of the universe, from the subatomic scale to the cosmological scale. In this chapter we study how interactions convert energy from one form to another. In the process we learn more about the concept of internal energy introduced in Chapter 5.

7.1 The effects of interactions

In the broadest sense, **interactions** are mutual influences between two objects that produce change (either physical change or a change in motion). As an example, consider a cart at rest on a horizontal track. The only way to get the cart to move is to make it *interact* with something else. We could, for instance, give it a shove or make it collide with another cart or fasten a magnet to it and push or pull it with another magnet.

Note that in each case we make the cart interact with something else. We can't make it change its state of motion without that something else: a hand, another cart, a magnet. If you look at Figure 4.19, you'll see that in each case where there is an interaction (*a*, *c*, and *d*), the interaction takes place between *two* objects: puck and floor, cart and cart, hand and cart.

An interaction that causes objects to accelerate can be either repulsive or attractive. A *repulsive interaction* is one in which the interacting bodies accelerate away from each other; an *attractive interaction* is one in which the interacting bodies accelerate toward each other. Some interactions are repulsive under some conditions and attractive under others, as illustrated in **Figure 7.1**.

CONCEPTS

7.1 (*a*) Imagine holding a ball a certain height above the ground. If you let the ball go, it accelerates downward. An interaction between the ball and what other object causes this acceleration? Is this interaction attractive or repulsive? (*b*) Once the ball hits the ground, its direction of travel reverses. Is this reversal the result of an attractive interaction or a repulsive one?

Figure 7.1 An interaction between two carts linked by a spring. When the spring is stretched, the interaction is attractive; when the spring is compressed, the interaction is repulsive.

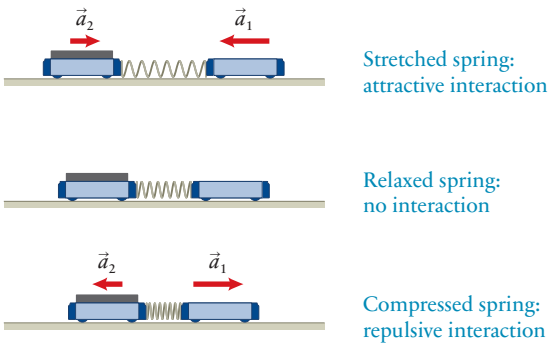

Figure 7.2 shows the x components of the velocities, momenta, and accelerations as well as the kinetic energies of two carts before and after an interaction. Cart 1, of inertia $m_1 = 0.12$ kg and initially at rest, is hit by cart 2, of inertia $m_2 = 0.24$ kg and initially moving at 0.55 m/s. The collision is elastic.

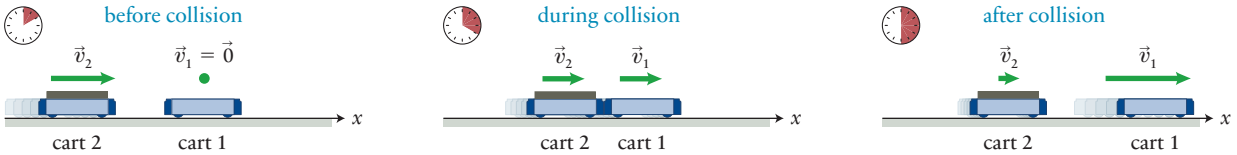
Figure 7.2*a* shows the x components of the velocities of the two carts. We've seen similar graphs before (Figure 4.8, for example). The x components of the final velocities are +0.73 m/s for cart 1 and +0.18 m/s for cart 2, and their relative speed remains 0.55 m/s, as it must for an elastic collision.

Figure 7.2*b* shows what happens to the x components of the momenta: One cart undergoes a momentum change in one direction, and the other cart undergoes an equal momentum change in the opposite direction. This is true at every instant: Even *during* the interaction, the momentum of the two-cart system is constant.

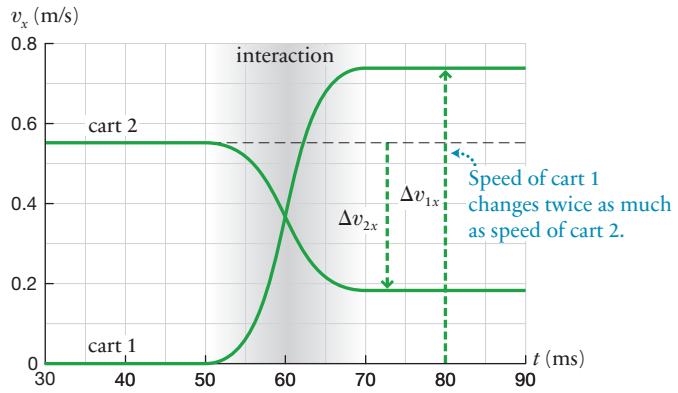
7.2 (*a*) Use Figure 7.2*a* to calculate the x components of the momenta of the two carts at $t = 30$, 60, and 90 ms. (*b*) What is the x component of the momentum of the system at each of these three instants?

Notice in Figure 7.2 that the interaction that causes the changes in velocity and momentum is not instantaneous; instead, it takes place over a certain time interval (represented by the shaded area in the graphs). The x component of the average acceleration of each cart during the interaction is equal to the change in the x component of the velocity for that cart divided by the duration of the interaction. Because the change in speed for cart 1 is twice as big as that for cart 2 (Figure 7.2*a*) and because the time interval over which the interaction takes place is the same for both carts, the magnitude of the average acceleration of cart 1 is twice that of cart 2. This result is a direct consequence of conservation of momentum.



As we shall see in Section 7.7, this relationship between the average accelerations of colliding bodies is true for the instantaneous accelerations as well. So, whenever two objects interact, the ratio of the x components of their accelerations is equal to the negative inverse of the ratio of their inertias.

EXAMPLE 7.1 Crash



A small car and a heavy truck moving at equal speeds in opposite directions collide head-on in a totally inelastic collision. Compare the magnitudes of (*a*) the changes in momentum and (*b*) the average accelerations of the car and the truck.

1 GETTING STARTED I begin by making a sketch of the situation before and after the collision (**Figure 7.3**). Before the collision, the truck and car both move at the same speed. After the totally inelastic collision, the two move as one unit with zero relative velocity. Because the inertia m_t of the truck is greater than the inertia m_c of the car, the momentum of the system points in the same direction as the direction of travel of the truck. The combined wreck must therefore move in the same direction after the collision.

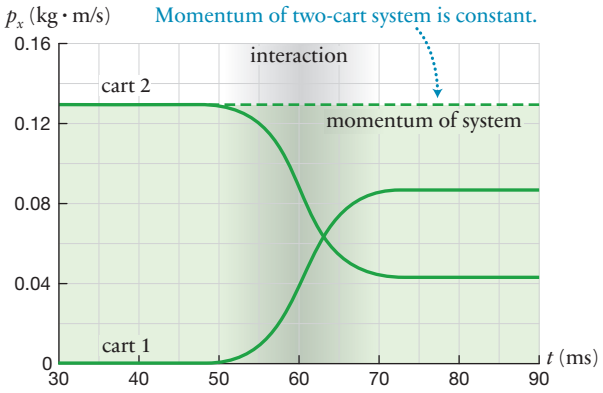


Figure 7.2 Conservation of momentum and kinetic energy in an elastic collision between two carts on a low-friction track. The inertia of cart 1 is 0.12 kg, and that of cart 2 is 0.24 kg.

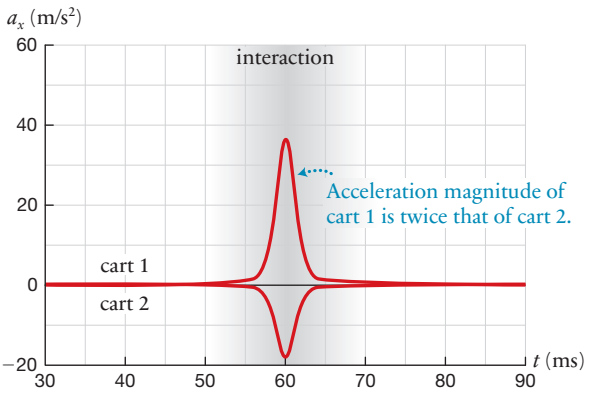
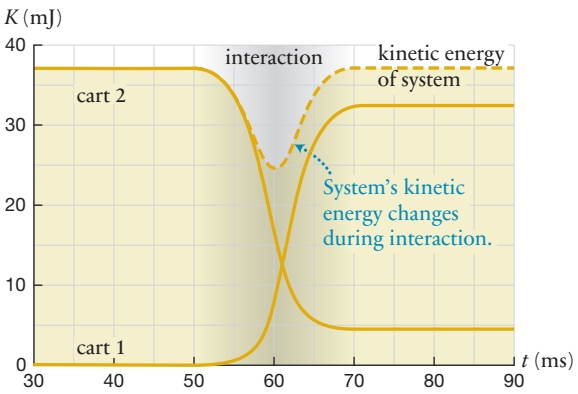
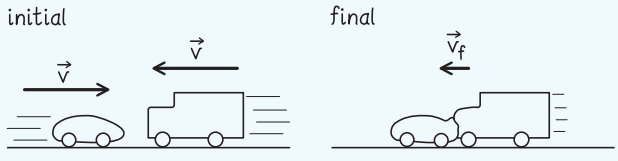


(*a*) Velocity



(*b*) Momentum

(*c*) Acceleration



(*d*) Kinetic energy

2 DEVISE PLAN To compare the changes in momentum, I can apply conservation of momentum to the isolated truck-car system. I can obtain the change in velocity by dividing the change in momentum by the inertia. Because the changes in velocity occur over the same time interval for both car and truck, and because the magnitude of the average acceleration is given by $\Delta v/\Delta t$, the ratio of the accelerations is the same as the ratio of the changes in velocity.

Figure 7.3 Example 7.1.

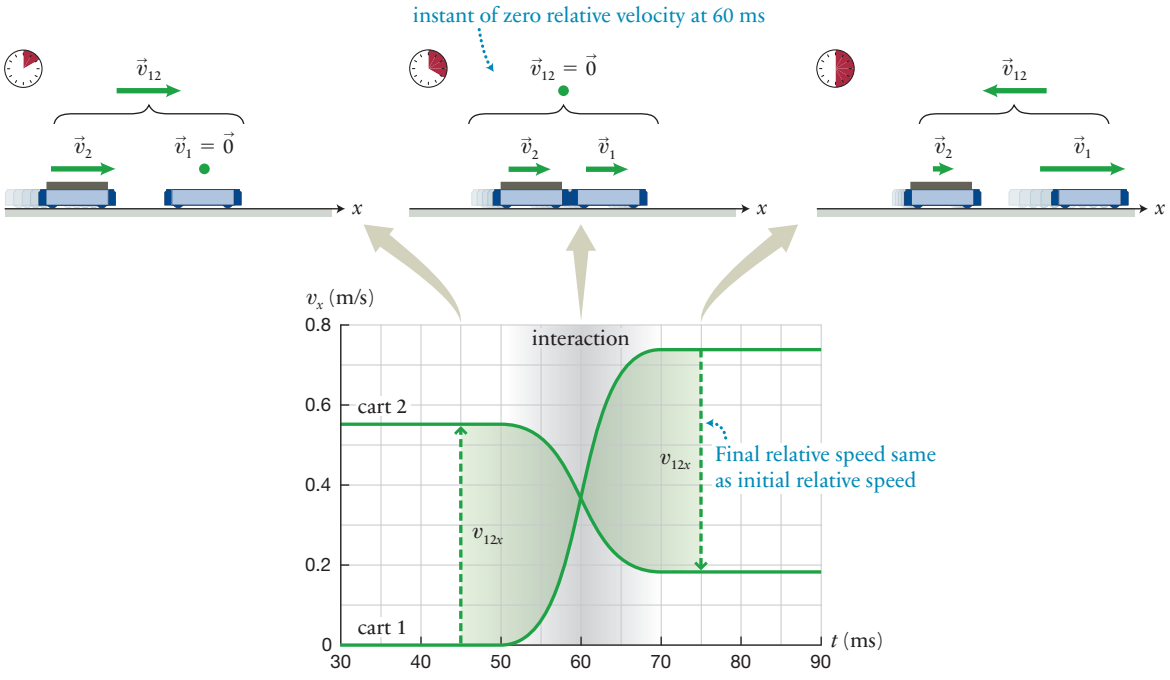
3 EXECUTE PLAN (*a*) The momentum of the isolated truck-car system does not change in the collision, and so the magnitudes of the changes in momentum for the car and the truck are the same. ✔

(*b*) The change in the x component of the velocity of the truck is $\Delta p_{tx}/m_t$, and the change in the x component of the velocity of the car is $\Delta p_{cx}/m_c$. Because $m_t > m_c$ and because the magnitudes of the changes in momentum are equal, I conclude that the magnitude of the velocity change of the car is larger than that of the truck. ✔

4 EVALUATE RESULT In any collision the magnitudes of the changes in momentum are the same for the two colliding objects, and so the answer to part *a* does not surprise me. That the magnitude of the velocity change for the car is larger also makes sense: As my sketch shows, the velocity of the car reverses, whereas the truck slows down somewhat but keeps traveling in the same direction.

CONCEPTS

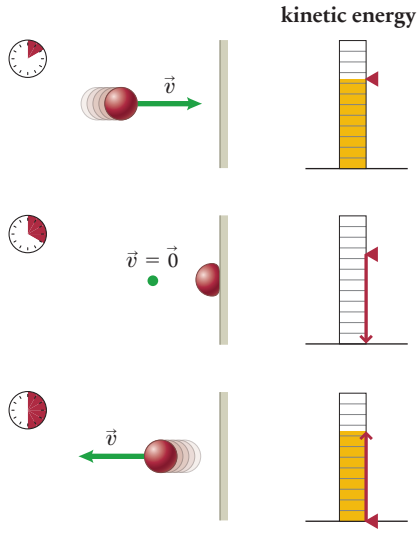
Figure 7.2*d* shows the kinetic energy of the two carts. Just like the momentum, the kinetic energy of each cart changes, but because the collision is elastic, the kinetic energy of the system before the interaction is the same as the kinetic energy of the system afterward. Note, however, that the kinetic energy of the system does not remain constant *during* the collision! Unlike momentum, the kinetic energy of a system of colliding objects changes during the interaction—even when the interaction is an elastic collision.



To see why, remember from Section 5.5 that kinetic energy's being constant is mathematically equivalent to saying that the relative speed of two objects is the same before and after an interaction. Whenever two objects collide, however, their relative speed has to change during the interaction. If the objects were to maintain a constant relative speed during the interaction, changing their velocities would change the momentum of the system, and this can't happen if the system is isolated. Consequently the kinetic energy of any system of colliding objects has to change during the interaction, regardless of the type of collision—elastic, inelastic, or totally inelastic.

Figure 7.4 illustrates the instant of zero relative velocity for the elastic collision shown in Figure 7.2. At the instant at which the two $v(t)$ curves intersect ($t = 60$ ms), the velocities are equal, and hence the relative velocity is zero at that instant. If you cover up the rightmost diagram at the top of Figure 7.2 (representing the carts' motion after the collision), you have no way of distinguishing this elastic collision from a *totally inelastic* one. In other words, in an elastic collision and a totally inelastic collision that have the same initial conditions, the same amount of kinetic energy is converted. The difference is that in the elastic collision any kinetic energy in the system before the collision that is converted to internal energy during the collision is all converted back to kinetic energy after the collision, whereas in the totally inelastic collision all of the initial kinetic energy converted to internal energy during the collision stays as internal energy and is not converted back to kinetic energy. The important point here is that, whenever two objects interact, their relative speed has to change, and therefore the kinetic energy of the system must change during the interaction.

7.3 (*a*) Use Figure 7.2*a* to calculate the kinetic energies of the two carts at $t = 30$, 60, and 90 ms. (*b*) What is the kinetic energy of the system at each instant?



This disappearance of kinetic energy doesn't jeopardize conservation of energy. The kinetic energy "missing" during the interaction has merely been temporarily converted to internal energy. Consider, for instance, a rubber ball thrown against a wall and bouncing off, as in **Figure 7.5**. At the instant of impact, the ball has zero velocity and has lost all the kinetic energy it had while moving toward the wall. Where has all this kinetic energy gone? It has gone into changing the shape of the ball. **Figure 7.6** shows a golf club striking a golf ball. The deformation of the ball at the instant of impact is

Figure 7.4 Even in an elastic collision between two carts, there is an instant at which the carts have the same velocity, which means that at that instant their relative velocity is zero.

CONCEPTS

Figure 7.5 At the instant the ball in this elastic collision has zero velocity, all its kinetic energy has been used to deform the ball (and, to a lesser extent, the wall). Thus, this energy is stored temporarily as elastic potential energy.

clearly visible. After impact, both the rubber ball of Figure 7.5 and the golf ball of Figure 7.6 regain their original shape, and the kinetic energy converted to internal energy during the interaction reappears as kinetic energy. Because the system (ball and wall in Figure 7.5, ball and club in Figure 7.6) is closed, the energy of the system remains constant throughout the collision. In the elastic collision in Figure 7.4, similar changes in shape take place in the carts, but these changes occur too fast and are too small to be observed easily.

In inelastic collisions, the system's kinetic energy is not the same before and after the collision. As in an elastic collision, there is an instant at which the relative speed of the colliding objects is zero, but unlike in an elastic collision, not all of the kinetic energy converted to internal energy during the interaction reappears as kinetic energy after the collision. Some of the kinetic energy is converted irreversibly to internal energy (see Section 5.3).

We can summarize the characteristics of an interaction:

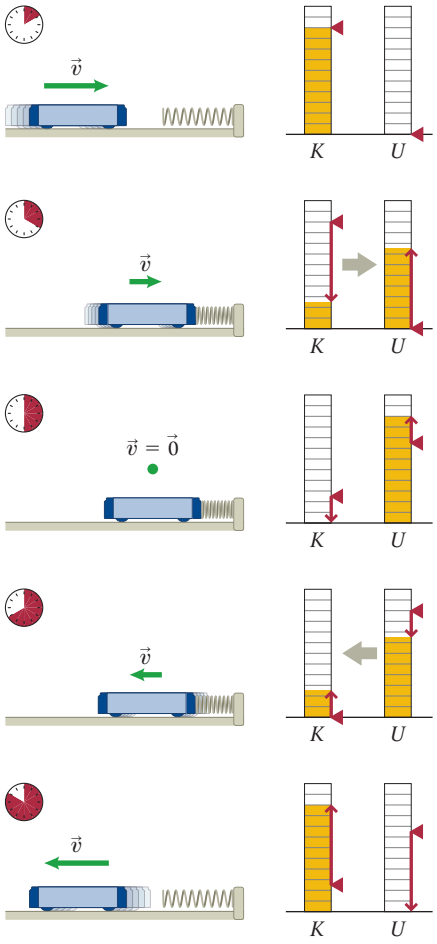
1. *Two objects* are needed.
2. The *momentum* of a system of interacting objects is the same before, during, and after the interaction (provided the system is isolated).

Moreover, for interactions that affect the motion of objects:

1. The ratio of the x components of the accelerations of the interacting objects is the negative inverse ratio of their inertias. Because the velocities of both objects change in an interaction, the *individual* momenta and kinetic energies change.
2. The system's *kinetic energy changes during the interaction*. Part of it is converted to (or from) some internal energy. In an elastic collision, all of the converted energy reappears as kinetic energy *after* the collision. In an inelastic collision, some of the converted kinetic energy reappears as kinetic energy; in a totally inelastic collision, none of the converted kinetic energy reappears.

7.4 (*a*) In Figure 7.5, what is the momentum of the ball during the collision? (*b*) Is the momentum of the ball constant before, during, and after the collision? If so, why? If not, why not, and for what system is the momentum constant?

Figure 7.6 At the instant of impact, a golf club and golf ball have zero relative speed, and much of the system's initial kinetic energy has gone into severe deformation of the ball (plus some deformation of the elastic club).



7.2 Potential energy

In any collision or interaction, the part of the converted kinetic energy that is temporarily stored in reversible changes in physical state and is then converted back to kinetic energy after the interaction is called **potential energy,** represented by U. Potential energy is a form of internal energy. The term *potential* refers to the fact that the energy has the potential to be converted back to kinetic energy—it is only temporarily stored. Just think of the rubber ball in Figure 7.5. At the instant it has zero velocity, all the energy that before impact was kinetic energy has gone into deforming the ball and is therefore now stored inside the ball. Because rubber is elastic, the stored energy has the potential to revert to kinetic energy. Similarly, if a cart on a track hits a spring mounted on a post (**Figure 7.7** on the next page), the cart compresses the spring, and all the energy that before impact was kinetic energy of the cart is temporarily converted to potential energy stored in the spring. As the spring returns to its original shape, this potential energy is converted back to kinetic energy of the cart. Throughout the interaction between the cart

CONCEPTS

Figure 7.7 Energy conversion during the compression of a spring by a moving cart.

and the spring, the sum of the kinetic and potential energies of the closed cart-spring system is constant.

How and where is energy stored as potential energy? It is stored in reversible changes in the *configuration state* of the system, by which I mean the spatial arrangement of the system's interacting components.

There are many forms of potential energy, all related to the way interacting objects arrange themselves spatially. If you hoist a boulder up through a third-floor window, you change the configuration state of the boulder-Earth system. As the boulder is hoisted upward, the form of potential energy called **gravitational potential energy** is stored in the Earth-boulder system. To see that the stored energy is potential energy, imagine cutting the rope that holds the boulder in place: The boulder accelerates as it tumbles back to Earth because of the gravitational interaction between it and Earth. As the boulder gains speed, its kinetic energy increases. Because energy is conserved and because the boulder-Earth system is closed, the gain in kinetic energy has to be compensated by a loss of potential energy associated with the changed configuration state.

Moving to the atomic level, whenever you squeeze a ball or a spring, you change the configuration state of the atoms that make up the ball or spring. Reversible deformations correspond to changes in **elastic potential energy.** In Figure 7.7, for instance, the kinetic energy of the cart is temporarily converted to elastic potential energy in the spring.

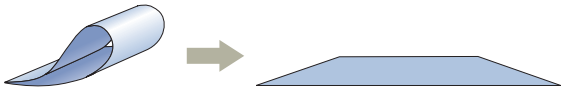
> **Potential energy is the form of internal energy associated with reversible changes in the configuration state of an object or system. Potential energy can be converted entirely to kinetic energy.**

EXERCISE 7.2 Launch

A ball is pressed down on a spring and then released from rest. The spring launches the ball upward. Identify the energy conversions that occur between the instant the ball is released and the instant it reaches the highest point of its trajectory.

SOLUTION As the spring expands, elastic potential energy stored in the spring is converted to kinetic energy of the ball. As the ball travels upward, it slows down and the kinetic energy is converted to gravitational potential energy of the ball-Earth system. ✔

7.5 In Figure 7.7, consider the cart's initial speed to be v_i. Assuming no potential energy is initially stored in the spring, how much potential energy is stored in the spring at the instant depicted in the middle drawing and at the instant depicted in the bottom drawing? Give your answers in terms of m, v_i, and v.



7.3 Energy dissipation

The part of the converted kinetic energy that does not reappear after an inelastic collision is said to be *dissipated* (in other words, irreversibly converted). To understand what happens to energy that is dissipated, try the following simple experiment with a crisp sheet of paper lying flat on a horizontal surface. Without making any folds, bend one end of the sheet over the other, as illustrated in **Figure 7.8*a***. If you remove your hand, the sheet straightens itself out. If you crumple up the sheet, however, as in Figure 7.8*b*, and then remove your hand, the crumpled sheet may expand a little, but it doesn't regain its original shape. There is an important difference between the two changes in shape. In Figure 7.8*a* the deformation takes place in a *coherent* manner, which means that at the atomic level, there is a pattern in the displacements of the atoms: They move orderly in rows, with each successive row experiencing a small displacement in the same direction as adjacent rows. As you bend the sheet in this fashion, you store potential energy in it. When you release the sheet, this potential energy appears as kinetic energy. In Figure 7.8*b*, the change in shape is *incoherent* because the atoms are displaced in random directions.

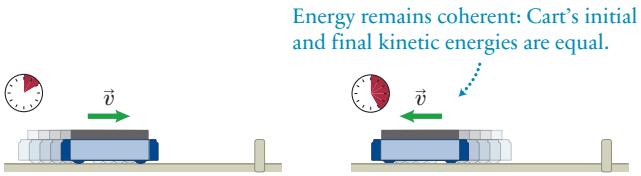
CONCEPTS

Figure 7.8 Reversible and irreversible deformations of a sheet of paper. If the sheet is simply bent (*a*), it returns spontaneously to its original shape; if it is crumpled (*b*), it does not.

(*a*) Coherent deformation: reversible

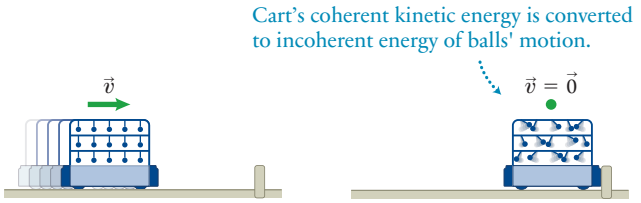
(*b*) Incoherent deformation: irreversible

The sheet can't straighten itself out because the randomly displaced atoms are in one another's way. Some of the smaller, less random deformations can restore themselves when you let go, but in general the energy used to do the crumpling has been irreversibly converted, producing a permanent deformation.



In addition to being dissipated to incoherent deformations, energy can be dissipated to incoherent motion, as shown in **Figure 7.9**. In Figure 7.9*a* a cart with a metal bar on top collides with a post that is anchored to the track. The collision is elastic, and so the cart's final kinetic energy is equal to the initial kinetic energy. In Figure 7.9*b* the metal bar has been replaced by a frame from which a large number of little balls are suspended. When this cart hits the post, the cart comes to a dead stop but the balls—initially at rest relative to the cart—chaotically jiggle back and forth in random directions. What has happened is that the initial kinetic energy of the cart has been converted to kinetic energy associated with the incoherent motion of the balls. We still have exactly the same amount of kinetic energy, but it has all become "internal." The initially coherent kinetic energy of the moving cart has been dissipated to the incoherent kinetic energy of the balls.

The experiment illustrated in Figure 7.9*b* is a large-scale model of what happens at the atomic scale in inelastic collisions. When a tennis ball bounces off a hard surface, part of the ball's kinetic energy is converted to incoherent energy of the atoms that make up the ball. (Imagine the atoms in the ball jiggling incoherently like the balls in Figure 7.9*b*.) Consequently the ball's kinetic energy after the bounce is less than that before the bounce, and so the rebound height is below the original height.



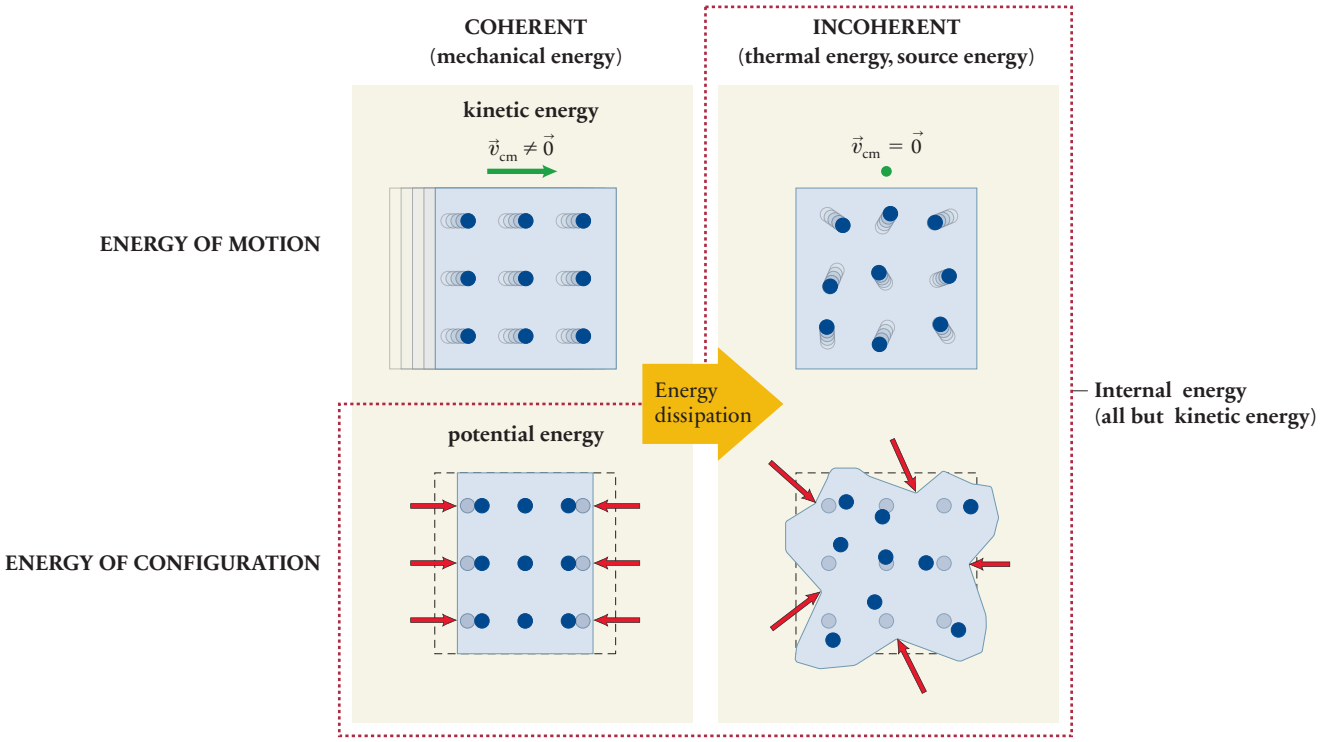
We can now give a complete classification of energy (**Figure 7.10** on the next page). All energy can be divided into two fundamental classes: energy associated with motion and energy associated with the configuration of interacting objects. Each class of energy comes in two forms: coherent and incoherent.

Figure 7.9 Reversible and irreversible collisions. In the totally inelastic collision in (*b*), the cart's coherent kinetic energy is converted completely to random energy of motion in the suspended balls.

(*a*) Cart rebounds elastically from barrier

(*b*) Barrier stops cart, putting balls in random motion

When all the atoms in an object move in a coherent fashion in the same direction—which means the entire object moves in that direction—the energy of motion is called *kinetic energy*. Energy stored in coherent changes in configuration is called *potential energy*. The sum of a system's kinetic energy and potential energy is called the system's **mechanical energy** or **coherent energy.**



In addition to this coherent energy, a system can have **incoherent energy** associated with the incoherent motion and configuration of its parts. An important part of a system's incoherent energy is its **thermal energy.** (As we shall see in Checkpoint 7.7, not all incoherent energy is thermal energy.) In most cases, the higher the thermal energy of an object, the higher its temperature—a concept we shall return to in Chapter 20. A rubber ball that has been squeezed repeatedly becomes noticeably hotter because the incoherent energy of the atoms that make up the ball has increased.

Here is a quick experiment you should try. Unfold a metal paper clip so that it takes on an S-shape. Holding the two ends, touch your lips with the central part of the clip—it should feel cold. Then vigorously bend the clip back and forth until it snaps in the middle and hold the two broken ends against your lips—the ends feel *hot*. The coherent energy you put into the back-and-forth bending has been converted to incoherent energy of the atoms in the metal (and some has gone into the breaking of the metal). When you hold the broken ends against your lips, you "feel" the atoms in the metal jiggling back and forth—they bounce against the atoms in your lips, transferring some of their energy to the atoms in your lips, thereby warming up your lips.

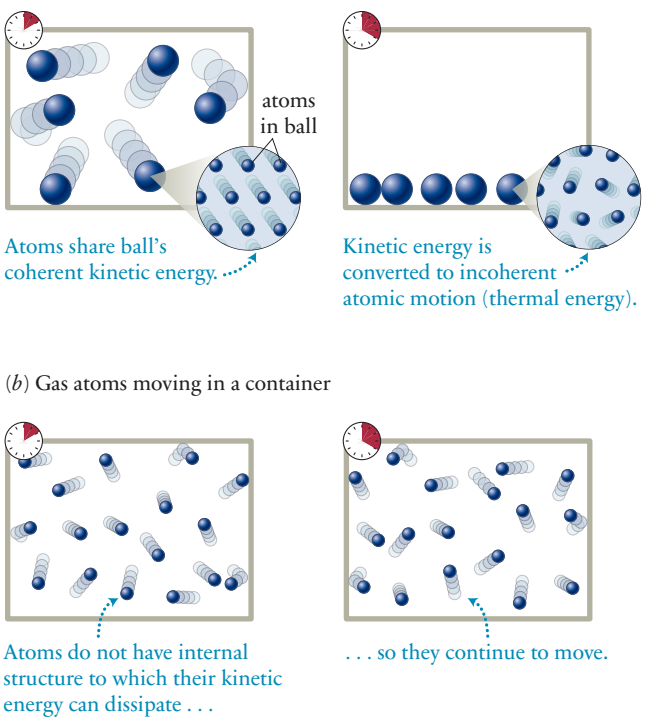
The sum of the system's incoherent energy and its potential energy is the system's *internal energy*.

CONCEPTS

Figure 7.10 Classification of energy.

Energy dissipation corresponds to the conversion of coherent energy into incoherent energy. This process is essentially irreversible—it is highly improbable that incoherent energy will revert by itself to a coherent form. Consider the cart in Figure 7.9*b*. If you shake it so that all the balls jiggle back and forth wildly, you are storing a certain amount of incoherent energy in the cart. If you then place the cart with the jiggling balls on the track against the post, this incoherent energy doesn't spontaneously turn into coherent kinetic energy of the cart as a whole—the cart does not suddenly start moving away from the post. What does happen, if you wait, is that the motion of the balls eventually stops. The kinetic energy of each ball gets dissipated, too—broken down into the incoherent jiggling of the individual atoms that make up each ball. (Because of the increased jiggling, the temperature of the balls increases but, as we shall see later, the temperature rise is imperceptibly small.)

This breaking down of the coherent energy of a large object into smaller units of incoherent thermal energy raises an interesting question: What happens to the energy once it has become thermal energy? Except for the motion of the Sun, the Moon, and other celestial objects, *all* motion we are familiar with comes to a stop unless something keeps it going. The stopping occurs because dissipation causes the coherent energy of the moving object to turn into incoherent energy. Does the energy of motion of the object's atoms dissipate, too? The answer to this question is *no*; at the atomic level, there simply is no way to further break down and randomize the energy.



To see that this is so, suppose we throw a bunch of rubber balls into a box (**Figure 7.11*a***). The balls initially bounce around, but if we look into the box a minute or so later, all of them are lying motionless on the bottom. All the energy is still there, but now it is inside the individual balls in the form of thermal energy. (The balls don't feel any warmer to you because the increase in thermal energy is so small as to be imperceptible.) Now suppose we observe a number of gas atoms randomly flying around in a container (Figure 7.11*b*). Provided the atoms do not interact with their environment, they keep flying around in the container *forever* because there are no smaller parts inside the atoms to which their kinetic energy can be dissipated.* And, because there is no dissipation at the atomic scale, nothing is required to keep atoms moving.

Friction, which occurs whenever two solid objects rub against each other or when an object moves through any fluid (air or water, say), is one of the causes of energy dissipation. Friction also causes wear and tear by removing microscopic pieces of material.

*What about the particles that make up the atoms—electrons, protons, neutrons? As we shall see in Chapter 20, these parts can store energy only in certain minimum increments that are larger than the typical kinetic energy of an atom, and so the kinetic energy of an atom cannot be further dissipated inside the atom.

CONCEPTS

Figure 7.11 (*a*) Bouncing balls come to rest because their kinetic energy is converted to internal kinetic energy of the atoms (thermal energy). (*b*) Atoms have no internal structure to which kinetic energy can be dissipated, so they keep moving.

This removal of material involves breaking the chemical bonds that hold atoms together. The incoherent configuration energy associated with the breaking of chemical bonds by friction or by crumpling, however, is many orders of magnitude smaller than the thermal energy generated in these processes (see the box "Coherent versus incoherent energy" on page 221). In general, we assume that the only type of dissipation caused by friction and crumpling is dissipation of mechanical energy into thermal energy. In Chapter 19 we shall examine energy dissipation and the accompanying conversion of coherent energy to incoherent energy in more detail.

7.6 Because of friction, a 0.10-kg hockey puck initially sliding over ice at 8.0 m/s slows down at a constant rate of 1.0 m/s^2 until it comes to a halt. (*a*) On separate graphs, sketch the puck's speed and its kinetic energy as functions of time. (*b*) To what form of energy is the kinetic energy of the puck converted?

7.4 Source energy

Because of the inexorable dissipation of mechanical energy, we need a source of energy—fuel, food, and so on—to either generate or maintain the mechanical energy of a system. For instance, the energy of gasoline is required to keep a car moving. Without this supply of energy, the car slows down as its kinetic energy dissipates because of friction. Likewise, to walk around the block, to send a message across the continent, to lift a basket, or to squeeze a spring, we need some source of energy.

Our current needs for mechanical energy are met using energy from a variety of sources—fossil and mineral fuels (oil, coal, natural gas), nuclear fuel, biomass fuel (food, wood, organic waste), water reservoirs, geothermal activity, solar radiation, and wind. We refer to the energy obtained from these sources collectively as **source energy.** Broadly speaking, there are four kinds of source energy: *chemical energy* (energy associated with the configuration of atoms inside molecules) released in such chemical reactions as the burning of oil, coal, gas, and wood and the metabolizing of food; *nuclear energy* (energy associated with the configuration of the nuclei of atoms) released in nuclear reactions; *solar energy* delivered by radiation from the Sun; and *stored solar energy* in the form of wind and hydroelectric energy.

Nearly all source energy can be traced back to energy delivered by the Sun. Nuclear reactions in the Sun create the solar radiation responsible for the energy content of biomass—the food we eat, the wood we burn. Fossil and mineral fuels were formed from the buried remains of plants and animals that lived and stored energy from the Sun millions of years ago. Wind energy results from the uneven heating of Earth's surface and atmosphere by solar radiation. Solar radiation evaporates the water that forms the clouds that deposit water in reservoirs behind dams.

7.7 How should chemical energy be classified in Figure 7.10?

CONCEPTS

To facilitate our accounting of energy in the rest of this book, we divide all energy into four categories: kinetic energy K, potential energy U, source energy E_s, and thermal energy E_{th} (**Figure 7.12a** on the next page). Interactions convert energy from one category to another, but conservation of energy requires that, for a closed system, the energy E of the system remains unchanged (Figure 7.12*b*).

Figure 7.13 on the next page illustrates the various types of energy conversions that can occur. Figure 7.13*a* shows the reversible conversion between the two forms of mechanical energy. Examples of this conversion are the (reversible) conversion between gravitational potential energy and kinetic energy for a ball thrown vertically upward and the (reversible) conversion between elastic potential energy and kinetic energy for a cart hitting a spring.

Figure 7.12 Energy accounting.

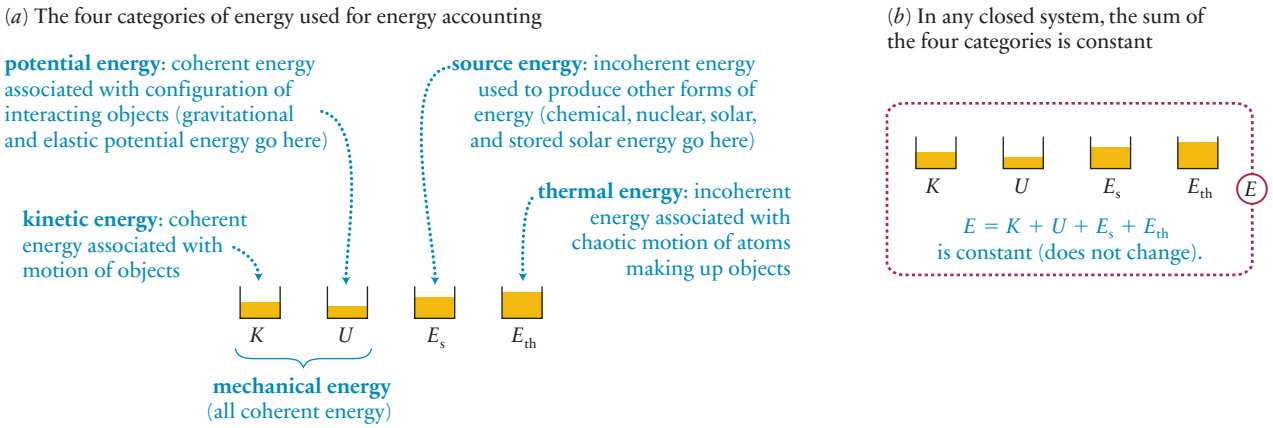


Figure 7.13*b* shows the (irreversible) dissipation of mechanical energy: Friction converts mechanical energy to thermal energy. Because of this dissipation, we need to convert source energy to maintain or generate mechanical energy (Figure 7.13*c*). For example, in a chemical reaction, the spatial arrangement of atoms inside molecules changes, and chemical energy is converted to kinetic energy of the reaction products (**Figure 7.14**). In the combustion of fuel in an engine, some of the kinetic energy of the combustion products can be converted to mechanical energy, but a large portion of it is converted to thermal energy (a car engine gets so hot that part of the mechanical energy generated by the engine must be used to turn a fan to *cool* the engine). Friction in the engine converts even more energy to thermal energy. Most of this thermal energy ends up either in the atmosphere or in the ground and cannot be easily recovered. We shall examine the generation of mechanical energy by *engines* in more detail in Chapter 21. For now, remember that the generation of mechanical energy from source energy is always accompanied by the generation of thermal energy, as illustrated in Figure 7.13*c*.

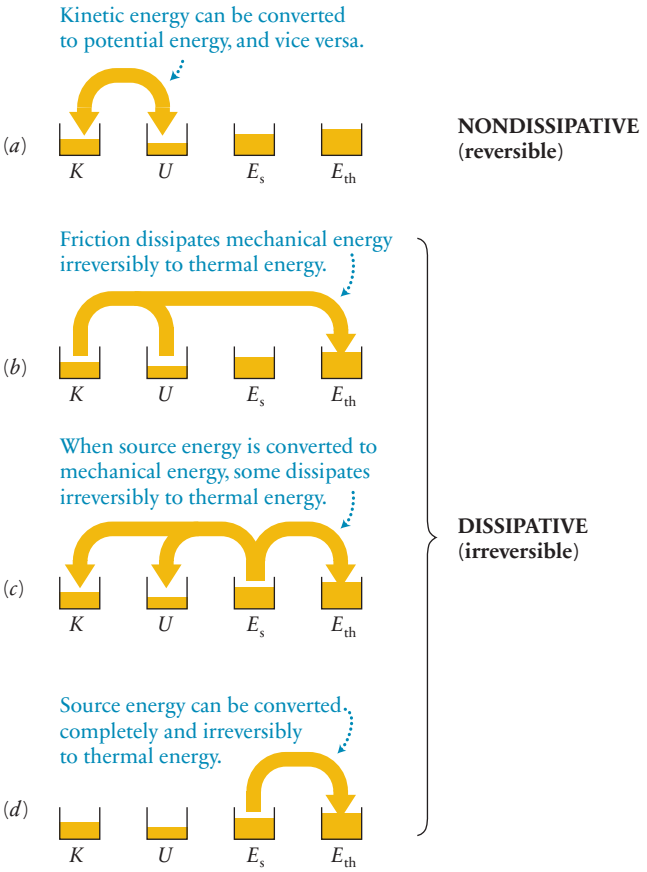
Figure 7.13 Energy conversion processes.



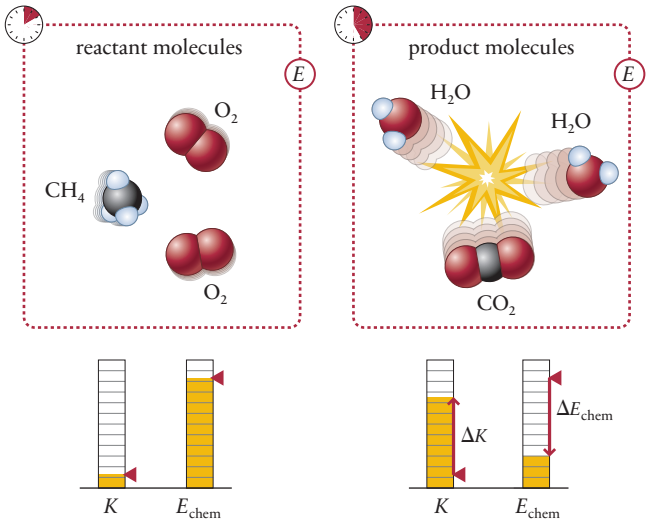


Figure 7.14 In the combustion of methane, each molecule of methane (CH_4) reacts with two oxygen molecules (O_2). The reaction rearranges the constituent atoms to form two water molecules (H_2O) and one molecule of carbon dioxide (CO_2). In the reaction, chemical energy originally in the reactant molecules is converted to kinetic energy of the products.

CONCEPTS

Figure 7.13*d* shows the conversion of source energy to thermal energy. An example of this process is the burning of gas or oil to heat our homes. The conversion of source energy to either mechanical or thermal energy is *irreversible*. The combustion of a methane-oxygen gas mixture, for example, causes permanent changes in the physical state of the gas mixture; it becomes a mixture of water and carbon dioxide. The reverse—obtaining methane from a mixture of water and carbon dioxide—is inconceivable even if energy is added to the system. Because of this irreversibility, the conversion of source energy to mechanical energy for transportation, heating, and so on—what we call *energy consumption*—decreases the available amount of source energy stored on Earth.

Because of dissipation, all forms of energy eventually are converted to thermal energy. As we shall see in Chapter 21, our ability to recover mechanical energy from thermal energy is very limited, however, making thermal energy not as useful as other forms of energy. Although some energy sources are renewable (solar, wind, water, biomass), they may not meet our future demands for energy. Consequently the supply of source energy is limited, and a number of sources, such as oil and gas, are likely to run out during the 21st century.

7.8 Whenever you leave your room, you diligently turn off the lights to "conserve energy." Your friend tells you that energy is conserved regardless of whether or not your lights are off. Which of you is right?

As we have seen, interactions that convert source energy to either mechanical or thermal energy and interactions that convert mechanical energy to thermal energy are irreversible. Irreversible interactions change the thermal energy in a system and are called **dissipative interactions;** reversible interactions do not change the thermal energy in a system and are called **nondissipative interactions.**

To determine whether or not an interaction is dissipative, all you need to do is ask yourself whether the interaction is reversible:

Interactions that cause reversible changes are nondissipative; those that cause irreversible changes are dissipative.

Consider a puck sliding to a stop on a rough surface. If you were to make a movie of this action and then play the movie in reverse, you would immediately notice that something is not correct: A puck lying on a

Coherent versus incoherent energy

To get a feel for the different types of energy, let's look at a very ordinary object—a pencil. How many types of energy are (or can be) stored in a pencil?

Coherent (mechanical) energy

Kinetic energy: If the pencil is at rest on your desk, its kinetic energy is zero. If, however, you throw it across the room, you give it a kinetic energy of about **0.01 J.**

Potential energy: To store potential energy in the pencil, you must change its configuration by squeezing or bending it. The pencil, being stiff, does not bend or squeeze easily, and so, if you are lucky, you might be able to store **0.1 J** of elastic potential energy in it before it snaps.

Incoherent energy

Thermal energy: Thermal energy is the energy associated with the random jiggling of atoms. It is impossible to convert all of this energy to another form, and so instead let's imagine you take the pencil out of a drawer and carry it around in your pocket so that its temperature rises from room temperature to body temperature. This rise in temperature increases its thermal energy by **100 J.** If you could convert this 100 J of thermal energy to kinetic energy, your pencil would be moving at the speed of an airplane!

Chemical energy: Being made of wood, a pencil stores chemical energy, which can easily be released. If you burn the pencil, the wood turns to ashes, and the configuration energy stored in the chemical bonds is converted to thermal energy, which you feel as heat. The energy converted by burning the pencil is **100,000 J,** an amount equal to the kinetic energy of a medium-sized car moving at 35 mi/h.

Broken chemical bonds: If you bend the pencil enough, it breaks. The energy required to break the chemical bonds in the pencil is about **0.001 J.** This amount is only 1% of that 0.1 J of potential energy you added by bending the pencil to just before its breaking point; the remaining 99% ends up as thermal energy: When the pencil snaps, the stress created by the bending is relieved, and the snapping increases the jiggling of the atoms.

This comparison of energies makes two important points that are valid more generally. First, coherent forms of energy are insignificant compared with incoherent forms—most of the energy around us is in the form of incoherent energy. Second, when energy is dissipated, virtually all of it becomes thermal energy; the incoherent configuration energy associated with deformation, breaking, and abrasion is generally negligible compared to the energies required to cause these changes.

rough surface doesn't spontaneously start moving. So the interaction between the rough surface and the puck is irreversible and therefore dissipative.

EXERCISE 7.3 Converting energy

For each of the following scenarios, choose a closed system, identify the energy conversions that take place, and classify each conversion according to the four processes shown in Figure 7.13. (*a*) A person lifts a suitcase. (*b*) A toy suspended from a spring bobs up and down. (*c*) A pan of water is brought to a boil on a propane burner. (*d*) A cyclist brakes and comes to a stop.

SOLUTION (*a*) Closed system: person, suitcase, and Earth. During the lifting, the potential energy of the Earth-suitcase system increases and the kinetic energy of the suitcase increases. The source energy is supplied by the person doing the lifting, who converts chemical (source) energy from food. In the process of converting this source energy, thermal energy is generated (the person gets hot). This process is represented in Figure 7.13*c*. ✔

(*b*) Closed system: toy, spring, and Earth. As the toy bobs, its height relative to the ground changes, its velocity changes, and the configuration of the spring changes. The bobbing thus involves conversions of gravitational and elastic potential energy and kinetic energy. This reversible process is represented in Figure 7.13*a*. ✔

(*c*) Closed system: pan of water and propane tank. As chemical (source) energy is released by burning the propane, the water is heated and its thermal energy increases. This process is represented in Figure 7.13*d*. ✔

(*d*) Closed system: Earth and cyclist. During the braking, the bicycle's kinetic energy is converted to thermal energy by friction (I'm ignoring the muscle source energy required to pull the brakes). This process is represented in Figure 7.13*b*. ✔

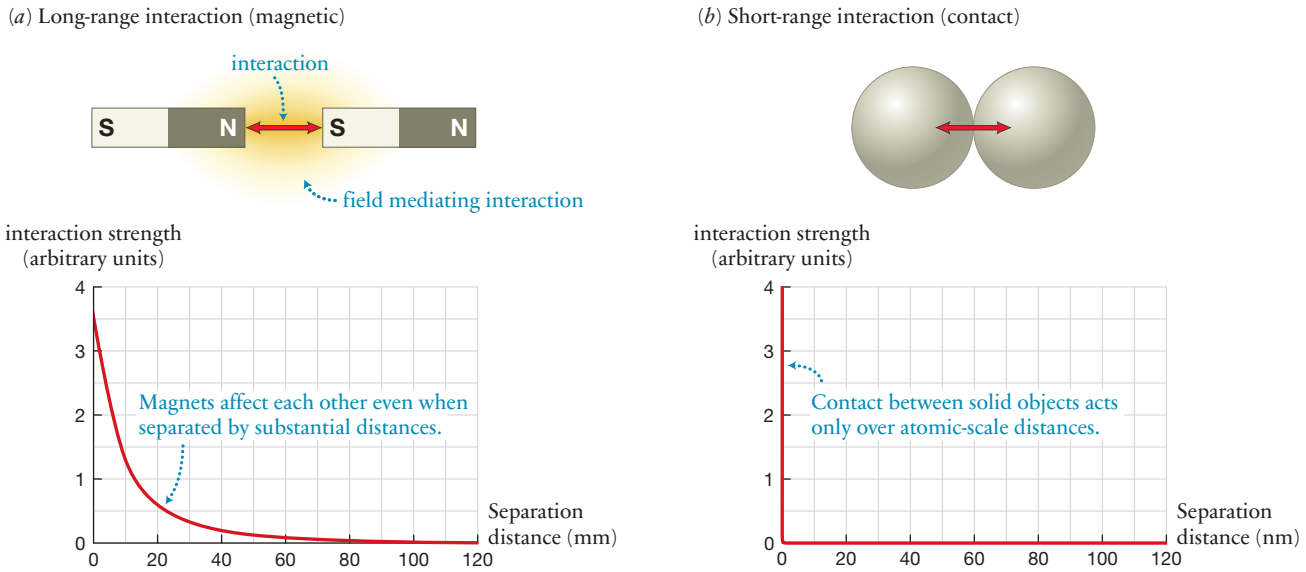
CONCEPTS

7.9 For each of the following processes, determine what energy conversion takes place and classify the interaction as dissipative or nondissipative. (Hint: Imagine what you would see if you played each situation in reverse.) (*a*) The launching of a ball by the expanding of a compressed spring, (*b*) the fall of a ball released a certain height above the ground, (*c*) the slowing down of a coasting bicycle, (*d*) the acceleration of a car.

7.5 Interaction range

The underlying mechanisms of interactions are still poorly understood, and as a result no one can answer the question, How do objects interact? From experience we know that not all objects interact with one another, but what determines when and why certain things do interact? It appears that each type of interaction occurs only between certain kinds of objects. So we assign to these objects certain *attributes* (magnetic strength, color, and so on) that are responsible for the interaction.

Note that it is the interaction that defines these attributes; we have no independent way of determining them. Consider a magnet, for instance. Is it a magnet because it behaves like one, or does it behave like a magnet because it *is* a magnet? In other words, do we say it has the attributes of a magnet because it interacts with other magnets? Or does it interact with other magnets because it has the attributes of a magnet?



What all this boils down to is that we *define* the properties of matter (whether something is magnetic or nonmagnetic, heavy or light, red or green) according to the interactions the matter takes part in (it interacts with iron or doesn't, Earth pulls on it strongly or not, it interacts with green light or with red). Matter can therefore be classified according to its interactions, and the attributes we give to various types of matter are just a convenient way of indicating the types of interactions they take part in.

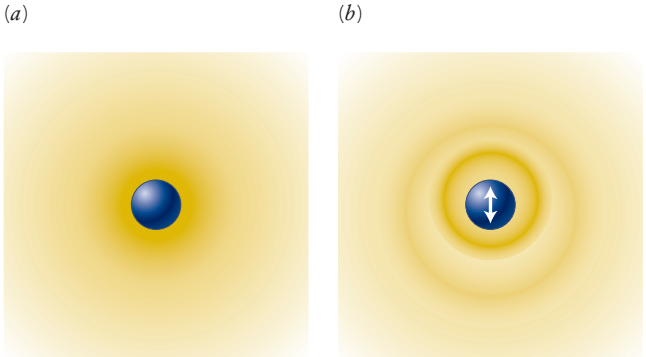
We are used to thinking of interactions as "things touching." You know, however, that a bar magnet can attract or repel another magnet located some distance away. The gravitational interaction works that way, too: Without any physical contact, Earth pulls downward on an object thrown up in the air. And so does electricity: On a day when the humidity is low, a plastic comb held near your head can attract your hair without physical contact.

To help us understand how things can interact without touching, we need to examine what we mean by *physical contact*. On the macroscopic level, *physical contact* means just that—two surfaces touching each other. On the atomic level, however, two atoms attract or repel each other even when they are separated by distances several times their size. Because all things are made up of atoms, there is no such thing as "touching" on the atomic level and therefore no such thing as physical contact. Your feet resting on the floor, for example, are supported by countless interactions between the atoms of your feet and those in the floor. So, on the atomic level, because atoms interact without physical contact, even feet "touching" floor is really an interaction without physical contact!

The strength of any interaction between two objects (in this context, think of *strength* in the sense of the magnitude of the acceleration caused by the interaction) is a function of the distance separating the objects. **Figure 7.15** shows how this strength varies with distance for magnets and for billiard balls. Because the magnets "feel" each other over quite a large distance, their interaction is said to be a *long-range* interaction.

Figure 7.15 Long-range interactions are perceptible over macroscopic distances; short-range ones, only over distances at the atomic scale or smaller. For instance, the contact interaction between two billiard balls is noticeable only when they are within nanometers of each other.

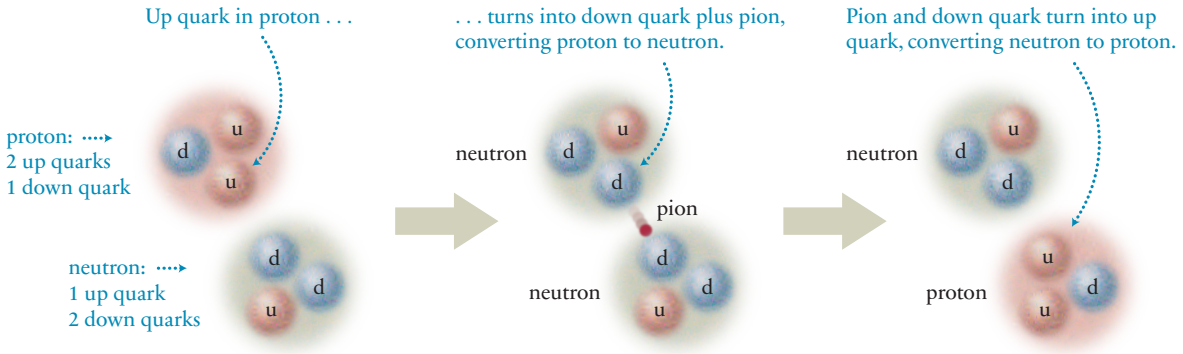
The repulsion (or, depending on the orientation of the magnets, attraction) is greatest at small separation distances but continues to be felt even at relatively large distances. In contrast, there is no noticeable interaction between the billiard balls even when they are separated by as little as the width of a hair. The two balls interact only when they are brought sufficiently close for the individual atoms to "feel" one another (which we call "touching"). The physical contact between two objects is thus a *short-range* interaction.



As these examples illustrate, our notion of physical contact has to do with how rapidly the effects of an interaction change with distance. The difference between the magnets and billiard balls in Figure 7.15 is their **interaction range**—the distance over which the interaction is appreciable.

One model widely used to picture long-range interactions is the **field** (**Figure 7.16***a*). In this model, every object is surrounded by a field, the properties of which are determined by the attributes of the object. An electrically charged object has an electric field, a magnetic object has a magnetic field, any object with what is called mass has a gravitational field, and so on. (We shall discuss mass in Chapter 13; for now just think of the mass of an object as a measure of how heavy that object is.) Interactions between objects are mediated by these fields.

Fields have an existence that is separate from the objects that create them. If I shake an object, the shaking creates a disturbance in the field that travels outward much like ripples on the surface of water (Figure 7.16*b*). The field of any object therefore contains information on the entire history of the object. As an example, think of watching the stars on a clear, moonless night. The light that reaches your eyes from some of the stars you are looking at was emitted as long as a million years ago. Some of the stars you see may not even exist anymore. Yet, via the ripples they once created in their fields—manifested as the light they once emitted—they are still interacting with you.



An alternative model explains interactions in terms of an exchange of fundamental particles called *gauge particles* (**Figure 7.17** and Checkpoint 7.10 on the next page). Physicists now believe that every interaction is caused by corresponding exchange of gauge particles. The existence of many of these particles has indeed been confirmed experimentally.

Figure 7.16 (*a*) The field of a stationary spherical object occupies the space around the object. The shading indicates the strength of the field—a measure of how strongly the object interacts with other objects. The field shown here rapidly decreases in strength with distance. (*b*) An outward traveling ripple in the field created by shaking the object.

CONCEPTS

Figure 7.17 Protons and neutrons (the particles that make up the atomic nucleus) can interconvert by exchanging a particle called a pion. As a result of this pion exchange, an example of which is shown schematically below, protons and neutrons exchange places continually as though "pulled through each other." The effect is that of an attractive interaction between protons and neutrons.

7.10 As an example of an interaction mediated by a "particle," imagine tossing a ball back and forth with a friend. You are both standing on an icy surface so slippery that friction is negligible. (*a*) Describe the effect the throwing and catching have on your momentum and your friend's momentum. (*b*) Is this an attractive or repulsive interaction? (*c*) Could you change the interaction into the other type?

7.6 Fundamental interactions

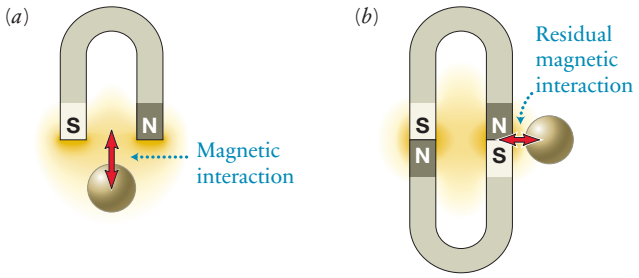
An interaction is **fundamental** if it cannot be explained in terms of other interactions. The interaction between, say, two colliding carts is not fundamental because it can be explained as being the result of the interactions between the atoms that make up the carts. Nor are the atomic interactions fundamental because they are the result of the interactions between the electrons and atomic nuclei that make up the atoms. And inside each atomic nucleus we observe yet another interaction responsible for holding the components of the nucleus together. This last interaction, the *strong interaction,* is today classified as fundamental because it cannot (yet) be explained in terms of other interactions.

All known interactions can be traced to just four fundamental interactions, two of them familiar from everyday life and two not (**Table 7.1**). The two familiar ones are the gravitational and electromagnetic interactions. We know of the gravitational interaction as Earth pulling on objects. A nylon sock interacts with a silk blouse in the clothes dryer via the electric part of the electromagnetic interaction; a magnet interacts with a refrigerator door via the magnetic part. The two unfamiliar fundamental interactions are those that take place inside the nuclei of atoms: the weak interaction and the strong interaction. A brief overview of the four fundamental interactions follows.

1. Gravitational interaction. This long-range interaction manifests itself as an attraction between all objects that have *mass,* and it is believed to be mediated by a still undetected gauge particle called the *graviton.* It is the weakest fundamental interaction, as manifested by the observation that you can't feel it acting between your body and any nearby object even though both of you possess mass. Only for very massive objects does this interaction become appreciable: The gravitational interaction between Earth and your body, for instance, *is* noticeable.

CONCEPTS

Table 7.1 Fundamental Interactions



Type	Required attribute	Relative strength	Range	Gauge particle	Propagation speed
gravitational	mass	1	∞	graviton?	c?
weak	weak charge	10^{25}	10^{-18} m	vector bosons	varies
electromagnetic	electrical charge	10^{36}	∞	photon	c
strong	color charge	10^{38}	10^{-15} m	gluon	c

The relative strength is a measure of the magnitude of the effects of these interactions on two protons separated by about 10^{-15} m. The question marks in the last two columns indicate that the information provided has not yet been verified experimentally. The symbol c represents the speed at which lights travels.

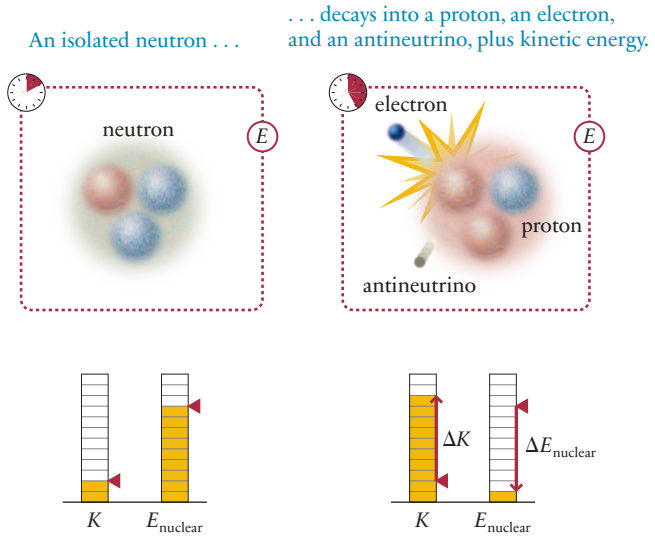
Figure 7.18 The matter in a galaxy is held together by the gravitational interaction—an indication of the tremendous range of this interaction.

Figure 7.19 Residual interaction. Even though a single magnet interacts strongly with a piece of iron, a pair of magnets joined together interacts only weakly with it.

Even though it is weak and decreases with increasing distance between the interacting objects, the gravitational interaction is what determines the structure of the universe on the cosmic scale. Other interactions generally cease to play a role on this scale. The existence of planetary systems and the shape of galaxies, such as the one shown in **Figure 7.18**, indicate the enormous range of the gravitational interaction.

2. Electromagnetic interaction. It is no exaggeration to say that this long-range interaction is responsible for most of what happens around us. It is responsible for the structure of atoms and molecules, for all chemical and biological processes, for the cohesion of matter into liquids and solids, for the repulsive interaction between objects such as a bat and ball, as well as for light and other electromagnetic radiation. The attribute of matter responsible for this interaction is called *electrical charge,* which comes in two varieties: *positive* and *negative,* each appearing in equal numbers in the universe. The gauge particle associated with the electromagnetic interaction is the *photon* (discussed in Chapter 34).

For moving charged particles, the electromagnetic interaction is complex (we'll treat it later in this book). For charged particles at rest, the interaction is either attractive or repulsive, depending on the combination of charged particles involved. Like the gravitational interaction, the strength of the electromagnetic interaction decreases rapidly with increasing distance between the interacting objects. However, the electromagnetic interaction of two protons separated by about 10^{-15} m is 36 orders of magnitude (that is, 10^{36} times) stronger than the gravitational interaction. To get a feel for just how large this difference in magnitude is, consider that the inertia of a grain of sand is "only" 33 orders of magnitude less than the inertia of Earth.



Because of the perfect balance in the amount of positive and negative charge in the universe and because the electromagnetic interaction is so strong, all matter tends to arrange itself in such a way that it is electrically neutral (which means it contains just as much positive as negative charge, and as a result most electromagnetic interactions cancel out). Consequently the electromagnetic interaction is most noticeable at the atomic scale. As noted in Section 7.5, what we call physical contact between objects is the result of the electromagnetic interactions between the individual charged parts of the atoms—interactions that average out at greater distances. The situation is much the same as when you let two horseshoe magnets attract each other until they stick together, as in **Figure 7.19**. The magnetic interaction between the pair and a piece of iron is considerably weaker than the interaction between that piece of iron and just one of the magnets. This is so because, in the pair, most of the effect of, say, the north pole of one magnet is canceled by the south pole of the other magnet. At short range, the canceling of the magnetic effect is not complete, and so there is some magnetic interaction—a *residual electromagnetic interaction*—left over, to interact weakly with the piece of iron.

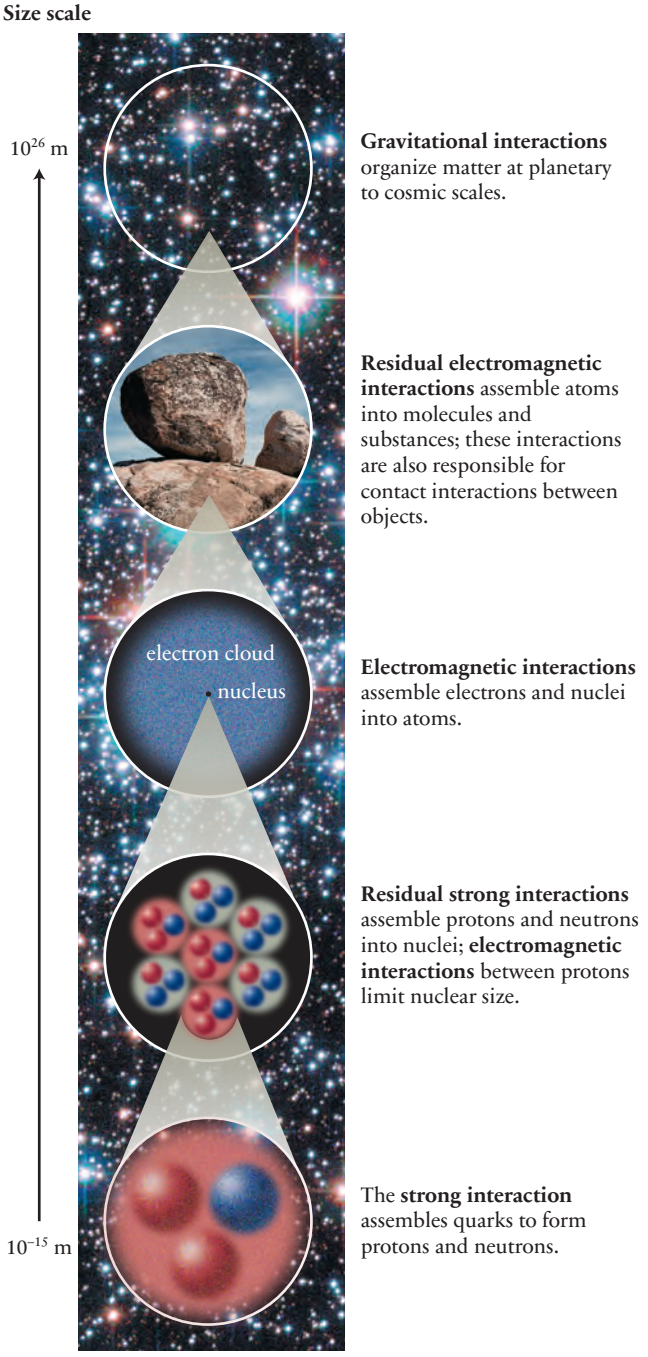
3. Weak interaction. This (usually) repulsive interaction is responsible for some radioactive decay processes and for the conversion of hydrogen to helium in stars. The weak interaction acts inside the nucleus between subatomic particles that possess an attribute called *weak charge* and causes most subatomic particles to be unstable. The gauge particles associated with the weak interaction are called *vector bosons*.

There is a strong parallel between the role of the electromagnetic interaction in chemical reactions and the role of the weak interaction in the decay of subatomic particles. Chemical reactions are caused by the rearrangement of electrons among atoms or groups of atoms (Figure 7.14). In the process, chemical energy is converted to (or from) kinetic energy of the reaction products. Likewise, when the weak interaction causes a subatomic particle to decay, internal energy of the

CONCEPTS

Figure 7.20 A neutron that is not part of an atomic nucleus disintegrates into a proton, an electron, and a subatomic particle called the antineutrino. This disintegration, called beta decay, is caused by the weak interaction.

original particle is converted to kinetic energy of the decay products (**Figure 7.20**).



There is a strong connection between the electromagnetic and weak interactions. Both can be considered manifestations of a single interaction called the *electroweak interaction*.

4. Strong interaction. The strong interaction acts between *quarks*, which are the building blocks of protons, neutrons, and other particles. This interaction, which can be either attractive or repulsive, is so strong that it completely overwhelms all other interactions among particles. The attribute required for this interaction is *color charge*, and the gauge particles are called *gluons*.

Quarks, like electrically charged particles and magnets, always arrange themselves in such a way that the effects of the strong interaction cancel. Only at very short range does some of the strong interaction remain. This *residual strong interaction* is responsible for holding the nucleus of an atom together.

In Table 7.1 note that the gravitational interaction—the fundamental interaction we are most directly aware of in our daily life—is orders of magnitude weaker than the other fundamental interactions. This is so because the stronger the interaction, the smaller the scale on which it affects the structure of the universe (**Figure 7.21**). (The size scale shown in the figure is not linear or logarithmic.)

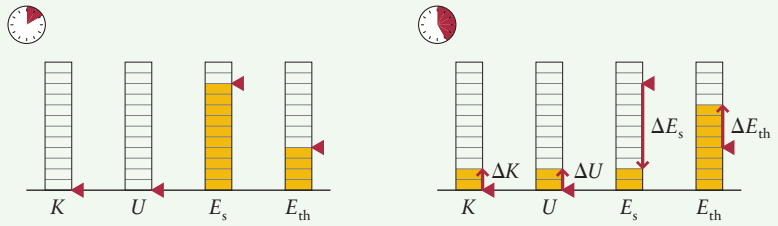
Figure 7.21 The fundamental interactions determine the structure of the universe at different scales. At the subatomic scale, the strong interaction is responsible for fusing quarks into the protons and neutrons that make up the atomic nucleus. The residual strong interaction and the weak interaction, along with electromagnetic repulsion between protons, are responsible for the formation and stability of atomic nuclei. Outside the atomic nucleus all effects of the strong interaction cancel, and weaker interactions become noticeable. Electromagnetic interactions between the positively charged atomic nucleus and negatively charged electrons are responsible for the structure of atoms. Interactions between atoms are due to residual electromagnetic interactions. At the human scale, the picture is dominated by the short-range residual electromagnetic interactions involved in contact between objects and by gravitational interactions. At the cosmic scale, the gravitational interaction plays the main role.

CONCEPTS

Self-quiz

1. Two carts are about to collide head-on on a track. The inertia of cart 1 is greater than the inertia of cart 2, and the collision is elastic. The speed of cart 1 before the collision is higher than the speed of cart 2 before the collision. (*a*) Which cart experiences the greater acceleration during the collision? (*b*) Which cart has the greater change in momentum due to the collision? (*c*) Which cart has the greater change in kinetic energy during the collision?
2. Which of the following deformations are reversible and which are irreversible: (*a*) the deformation of a tennis ball against a racquet, (*b*) the deformation of a car fender during a traffic accident, (*c*) the deformation of a balloon as it is blown up, (*d*) the deformation of fresh snow as you walk through it?
3. Translate the kinetic energy graph in Figure 7.2 into three sets of energy bars: before the collision, during the collision, and after the collision. In each set, include a bar for K_1, a bar for K_2, and a bar for the internal energy of the system, and assume that the system is closed.
4. Describe a scenario to fit the energy bars shown in **Figure 7.22**. What happens during the interaction?

Figure 7.22



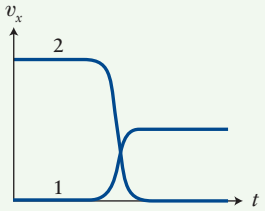


Figure 7.23

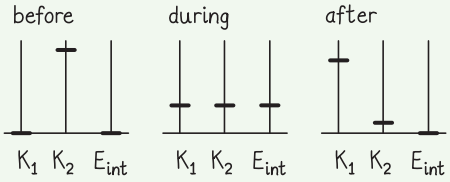


5. Describe a scenario to fit the velocity-versus-time curves for two colliding objects shown in **Figure 7.23**. All motion is confined to the x axis. What happens to the initial energy of the system of colliding objects during the interaction?

Answers

1. (*a*) The cart with the smaller inertia experiences the greater acceleration (see Figure 7.2). (*b*) The magnitude of $\Delta\vec{p}_1$ is the same as the magnitude of $\Delta\vec{p}_2$, but the changes are in opposite directions because the momentum of the system does not change during the collision. (*c*) $|\Delta K_1| = |\Delta K_2|$, but the changes are opposite in sign because the kinetic energy of the system before the elastic collision has to be the same as the kinetic energy of the system afterward.
2. (*a*) Reversible. The ball returns to its original shape. (*b*) Irreversible. The fender remains crumpled. (*c*) Irreversible. The balloon does not completely return to its original shape after deflation. (*d*) Irreversible. Your footprints remain.
3. See **Figure 7.24**. Before the collision $K_1 = 0$, K_2 is maximal, and $E_{int} = 0$; during the collision K_1, K_2, and E_{int} are all about one-third of the initial value of K_1; after the collision K_1 is about 7/8 of the initial value of K_1, K_2 is about 1/8 of the initial value of K_1, and $E_{int} = 0$. Because the system is closed, its energy is constant, which means the sum of the three bars is always the same.

Figure 7.24

4. During the interaction, eight units of source energy is converted to two units of kinetic energy, two units of potential energy, and four units of thermal energy. One possible scenario is the vertical launching of a ball. Consider the system comprising you, the ball, and Earth from just before the ball is launched until after it has traveled some distance upward: The source energy goes down (you exert some effort), thermal energy goes up (in the process of exerting effort you heat up), kinetic energy goes up (the ball was at rest before the launch), and so does potential energy (the distance between the ground and the ball increases).
5. The graph represents an inelastic collision because the relative velocity of the two objects decreases to about half its initial value. In order for the momentum of the system to remain constant, the inertia of object 1 must be twice that of object 2. Possible scenario: Object 2, inertia m, collides inelastically with object 1, inertia $2m$. The collision brings object 2 to rest and sets object 1 in motion. The interaction converts the initial kinetic energy of object 2 to kinetic energy of cart 1 and to thermal energy and/or incoherent configuration energy of both carts.

7.7 Interactions and accelerations

Let us now prove a statement made in Section 7.1: For interactions that affect the motion of objects, the ratio of the x components of the accelerations of the interacting objects is equal to the negative inverse of the ratio of their inertias.

Whenever two objects interact, they can exchange momentum and energy. If we consider the two-object system to be isolated during the interaction, conservation of momentum requires that, at any instant during the interaction, the momentum changes of the two objects be equal in magnitude and opposite in direction:

$$\Delta\vec{p}_1 = -\Delta\vec{p}_2. \tag{7.1}$$

Because the change in momentum for each object is caused by the interaction with the other object, the time interval over which the momenta change—the duration of the interaction—is the same for both objects. If we denote this time interval by Δt, we can write

$$\frac{\Delta\vec{p}_1}{\Delta t} = -\frac{\Delta\vec{p}_2}{\Delta t}. \tag{7.2}$$

If the inertias m_1 and m_2 of the two objects are not changed by the interaction, we have, from the definition $\vec{p} \equiv m\vec{v}$,

$$\frac{m_1\Delta\vec{v}_1}{\Delta t} = -\frac{m_2\Delta\vec{v}_2}{\Delta t}. \tag{7.3}$$

Using the definition of acceleration given as Eq. 3.21,

$$\lim_{\Delta t\to 0}\frac{\Delta v_x}{\Delta t} \equiv a_x, \tag{7.4}$$

we take the limit of both sides of Eq. 7.3 as Δt goes to zero and get for the x components of the accelerations:

$$m_1a_{1x} = -m_2a_{2x}. \tag{7.5}$$

Hence, both objects accelerate during the interaction, and the ratio of the x components of their accelerations is equal to the negative inverse of the ratio of their inertias:

$$\frac{a_{1x}}{a_{2x}} = -\frac{m_2}{m_1}. \tag{7.6}$$

This relationship between the accelerations of two interacting objects of constant inertia holds for all interactions in an isolated two-object system, regardless of what happens to the energy during the interaction.

QUANTITATIVE TOOLS

7.11 A 1000-kg compact car and a 2000-kg van, each traveling at 25 m/s, collide head-on and remain locked together after the collision, which lasts 0.20 s. (*a*) According to Eq. 7.6, their accelerations during the collision are unequal. How can this be if both initially have the same speed and the time interval during which the collision takes place is the same amount of time for both? (*b*) Calculate the average acceleration in the direction of travel experienced by each vehicle during the collision.

7.8 Nondissipative interactions

Conservation of energy requires that the energy of any closed system remain unchanged. Using the four categories of energy introduced in Section 7.4, we can write this in the form

$$\Delta E = \Delta K + \Delta U + \Delta E_s + \Delta E_{th} = 0 \quad \text{(closed system)}. \tag{7.7}$$

For nondissipative interactions, there are no changes in either the source energy or the thermal energy of the system: $\Delta E_s = 0$ and $\Delta E_{th} = 0$. Thus the only energy conversions allowed in nondissipative interactions are reversible transformations between kinetic energy K and potential energy U. For these types of interactions Eq. 7.7 simplifies to

$$\Delta E = \Delta K + \Delta U = 0 \quad \text{(closed system, nondissipative interaction)}. \tag{7.8}$$

If we introduce the mechanical energy of a system

$$E_{mech} = K + U, \tag{7.9}$$

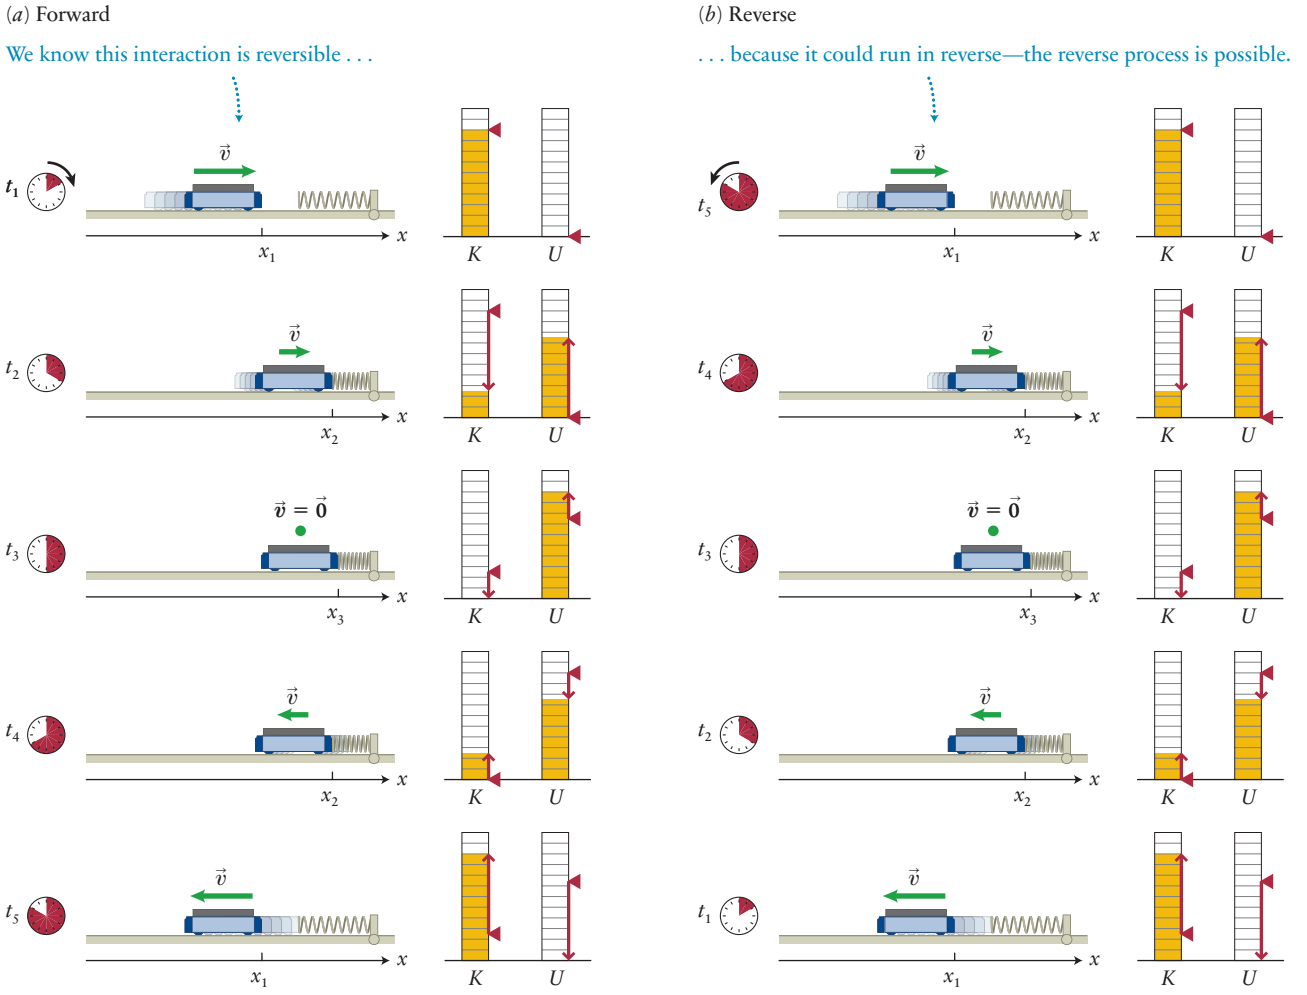
we can write Eq. 7.8 as

$$\Delta E_{mech} = 0 \quad \text{(closed system, nondissipative interaction)}. \tag{7.10}$$

In words, in a closed system in which only nondissipative interactions take place, the mechanical energy (the sum of the kinetic and potential energies) is constant.

We can deduce an important property of potential energy from the reversibility of nondissipative interactions. Consider the nondissipative interaction shown in **Figure 7.25*a*** on the next page. A cart, initially traveling to the right, bounces off a spring. The cart interacts with the spring, which is anchored to Earth. The system comprising the cart, spring, track, and Earth is closed. The interaction between the cart and Earth (which we'll consider to include the track and the spring) is nondissipative because it is reversible: Reversing the sequence yields the same result. From the motion of the cart, you cannot tell if time runs from t_1 to t_5 or the other way around (Figure 7.25*b*).

This reversibility means that the cart's kinetic energy at some given position x must be the same on the way in and on the way out. For example, K_{cart} at t_2—when the front end of the cart is at x_2—must be the same as K_{cart} at t_4—when the front end returns to x_2. Because K_{Earth} doesn't change (see Checkpoint 7.12), Eq. 7.8 yields



$$\Delta K_{cart} = -\Delta U_{spring}, \tag{7.11}$$

where U_{spring} is the elastic potential energy associated with the shape of the spring. Consequently, the potential energy in the spring must also have the same value at any given position on the way in and on the way out. In other words, the potential energy stored in the spring must be a unique function of position: U_{spring} has a definite value at each position x of the end of the spring. More generally, the potential energy of any system (that is, the portion of the system's internal energy that is associated with reversible configuration changes) can be written in the form

$$U = U(x), \tag{7.12}$$

where $U(x)$ is a unique function of a position variable x that quantifies the configuration of the system.

Figure 7.25 Reversible interaction between a cart and a spring anchored to a post.

A direct consequence of this dependence of potential energy on position is that the change in the kinetic energy of an object that moves from a position x_1 to a position x_2 during some nondissipative interaction depends *only* on those positions, not on the path taken by the object. Example 7.4 shows how this applies to the specific case of a cart bouncing off a spring.

7.12 Use the conservation laws to show that, when the spring in Figure 7.25 expands, the change in the kinetic energy of Earth is negligible and we are therefore justified in using Eq. 7.11.

EXAMPLE 7.4 Path independence of change in potential energy

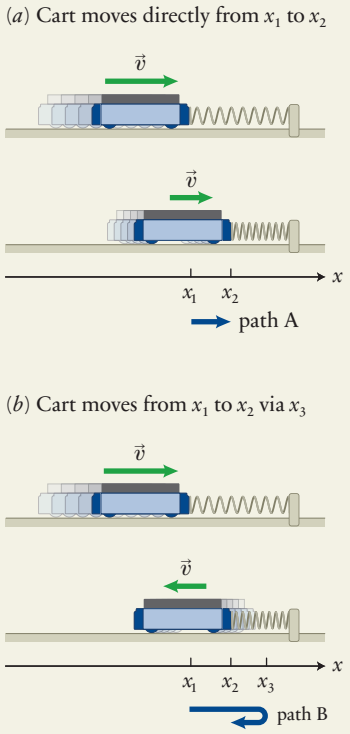


Figure 7.26 shows a cart striking a spring. In Figure 7.26*a*, consider the motion of the cart along the direct path from the initial position x_1, which is the position at which the cart makes initial contact with the free end of the spring, to the position x_2 (path A). In Figure 7.26*b*, consider the motion along the path from x_1 to the position of maximum compression x_3 and then back to x_2 (path B). Show that the change in the cart's kinetic energy is the same for both paths if the interaction caused by the spring is reversible.

❶ **GETTING STARTED** As the cart moves from x_1 to x_2 along path A, the spring is compressed and the cart's kinetic energy steadily decreases. Along path B, the spring is first compressed and the cart comes to a stop at x_3. The spring then expands, accelerating the cart back to x_2. To solve this problem, I'll consider the closed system made up of the cart, the spring, and Earth.

❷ **DEVISE PLAN** The change in the cart's kinetic energy is given by Eq. 7.11. Therefore if the change in the elastic

QUANTITATIVE TOOLS

Figure 7.26 Example 7.4.

potential energy of the spring is the same along both paths, then the change in the kinetic energy of the cart must also be the same along both paths. I'll first determine the change in potential energy between the initial and final positions of path A, then do the same between the initial and final positions of the two parts of path B.

3 EXECUTE PLAN Because the potential energy associated with a reversible interaction is a function of x only (Eq. 7.12), the change in elastic potential energy along path A is

$$\Delta U_{\text{path A}} = U_f - U_i = U(x_2) - U(x_1).$$

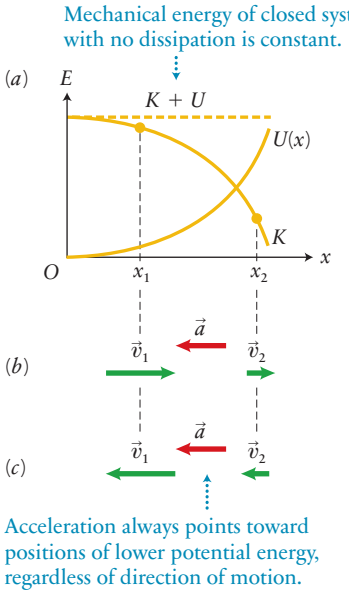
Along path B I have two contributions to ΔU_{spring}: an increase in U from x_1 to x_3 and a decrease from x_3 to x_2:

$$\begin{aligned}\Delta U_{\text{path B}} &= \Delta U_{13} + \Delta U_{32} \\ &= [U(x_3) - U(x_1)] + [U(x_2) - U(x_3)] \\ &= U(x_2) - U(x_1) = \Delta U_{\text{path A}}. \checkmark\end{aligned}$$

So, the change in the cart's kinetic energy is the same for both paths.

4 EVALUATE RESULT The change in the cart's kinetic energy is independent of the path joining x_1 and x_2 even though the cart ends up moving in opposite directions along the two paths. This is because the change in potential energy ΔU_{12} depends only on the coordinates of the initial and final positions x_1 and x_2.

Another way to see that this must be true is to consider only the motion from x_2 to x_3 and back. From x_2 to x_3 all the kinetic energy of the cart is converted to elastic potential energy of the spring. From x_3 to x_2 the elastic potential energy is converted back to kinetic energy, and so the motion from x_2 to x_3 and back to x_2 doesn't change the cart's kinetic energy. (Remember that kinetic energy is always positive and independent of the direction of travel.)



7.13 Show that, in Figure 7.26, the change in potential energy along a round trip from position x_1 to position x_2 and then back to x_1 is zero.

We can deduce a very important point from the fact that potential energy is a unique function of position. Consider, for example, a closed system with the potential energy function $U(x)$ shown in **Figure 7.27a**. If there is no dissipation, the sum of the kinetic and potential energies of this closed system is constant. Therefore, because the potential energy increases with increasing x, the kinetic energy must decrease with increasing x. So, if we consider two positions x_1 and $x_2 > x_1$, we see that the kinetic energy must be smaller at x_2 than at x_1. If the object whose kinetic energy is represented in the graph moves toward increasing x, as shown in Figure 7.27*b*, it slows down, and so its acceleration must point to the left. If, on the other hand, the object moves toward smaller x, as shown in Figure 7.27*c*, it speeds up, and so its acceleration again points to the left. This means that the object tends to be accelerated in the direction of lower potential energy, regardless of its original direction of motion. Quite generally we can state:

The parts of any closed system always tend to accelerate in the direction that lowers the system's potential energy.

In Figure 7.26, for example, the potential energy increases as the free end of the spring moves to the right. The free end therefore accelerates the

Figure 7.27 Acceleration in a closed system that has no energy dissipation.

cart to the left. This acceleration slows the cart down as it moves to the right and speeds it up as it moves to the left.

7.14 Consider a ball launched upward. Verify that its acceleration points in the direction that lowers the gravitational potential energy of the Earth-ball system.

7.9 Potential energy near Earth's surface

As a first example of how to determine the potential energy for a nondissipative interaction, consider a familiar interaction: the gravitational interaction near Earth's surface. As we discussed in Chapter 3, it is an experimental fact that, in the absence of air resistance, all objects near the ground fall with constant acceleration $g = 9.8\ \text{m/s}^2$. If we ignore friction, this interaction is nondissipative because free fall is reversible (see Checkpoint 7.9*b*).

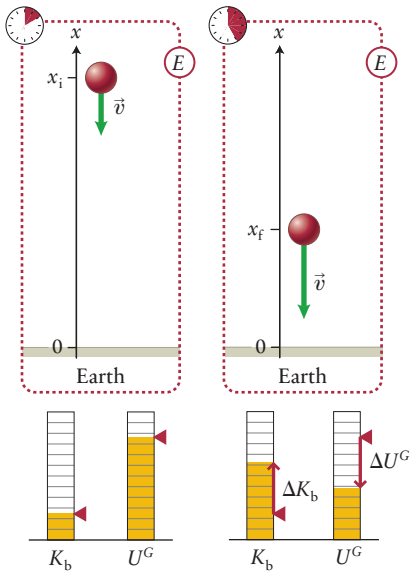
If we release a ball from a certain height above the ground, the ball gains kinetic energy as it accelerates downward. As the ball falls, the distance between it and the ground decreases so that the (gravitational) configuration of the Earth-ball system and hence the potential energy associated with this configuration change. Because the ball and Earth constitute a closed system and because the gravitational interaction is nondissipative, we can use Eq. 7.8 to relate the change in the ball's kinetic energy to a change in the gravitational potential energy U^G (as we found in Checkpoint 7.12, Earth's kinetic energy doesn't change):*

$$\Delta U^G + \Delta K_b = 0, \tag{7.13}$$

where ΔU^G is the change in the gravitational potential energy of the Earth-ball system and ΔK_b is the change in the ball's kinetic energy.

Equation 7.13 allows us to obtain ΔU^G if we know ΔK_b. Using some of the kinematics from Chapter 3, we can obtain an expression that gives ΔU^G in terms of physical quantities other than the kinetic energy. Let's begin by looking at our ball as it falls from x_i to x_f in a time interval $\Delta t = t_f - t_i$. As illustrated in **Figure 7.28**, at t_i the ball is at a height x_i above the ground and the x component of its velocity is $v_{x,i}$; at t_f the ball is at x_f and the x component of its velocity is $v_{x,f}$. In that time interval, the ball accelerates with a constant acceleration given by Eqs. 3.1 and 3.14:

$$a_x = \frac{\Delta v_x}{\Delta t} = -g. \tag{7.14}$$



Next we turn to Eq. 3.7, which when we substitute $-g$ for a_x is

$$\Delta x = v_{x,i}\Delta t - \tfrac{1}{2}g(\Delta t)^2. \tag{7.15}$$

Rearranging Eq. 7.14 gives $\Delta t = -\Delta v_x/g$, and substituting this expression for Δt into Eq. 7.15 gives us

$$\Delta x = -v_{x,i}\frac{\Delta v_x}{g} - \tfrac{1}{2}g\left(\frac{\Delta v_x}{-g}\right)^2. \tag{7.16}$$

Figure 7.28 A freely falling ball gains kinetic energy at the expense of the gravitational potential energy of the (closed) Earth-ball system.

*We use superscripts to indicate the type of interaction associated with the potential energy: G for gravitational, E for electric, and so on.

QUANTITATIVE TOOLS

Expanding the delta notations and working through the algebra, we get

$$x_f - x_i = -\frac{2v_{x,i}(v_{x,f} - v_{x,i}) + v_{x,f}^2 - 2v_{x,i}v_{x,f} + v_{x,i}^2}{2g} = -\frac{v_f^2 - v_i^2}{2g}, \qquad (7.17)$$

where we have used the fact that $v_x^2 = v^2$. Multiplying through by g and by the inertia m_b of the ball, we get

$$m_b g(x_f - x_i) + \tfrac{1}{2}m_b(v_f^2 - v_i^2) = 0. \qquad (7.18)$$

The second term on the left is precisely the change in the ball's kinetic energy, and so comparison with Eq. 7.13 tells us that the first term must be ΔU^G, the change in gravitational potential energy we are looking for. When the distance between the ball and the ground changes by an amount Δx, the gravitational potential energy changes by an amount $m_b g \Delta x$.

Because *all* objects falling near Earth's surface experience the same acceleration, this reasoning holds for any object. So, if the vertical coordinate of any object of inertia m changes by Δx, the change in the gravitational potential energy of the Earth-object system is

$$\Delta U^G = mg\Delta x \quad \text{(near Earth's surface)}. \qquad (7.19)$$

7.15 Suppose you raise this book (inertia $m = 3.4$ kg) from the floor to your desk, 1.0 m above the floor. (*a*) Does the gravitational potential energy of the Earth-book system increase or decrease? (*b*) By how much? (*c*) Conservation of energy requires that this change in potential energy be compensated for by a change in energy somewhere in the universe. Where?

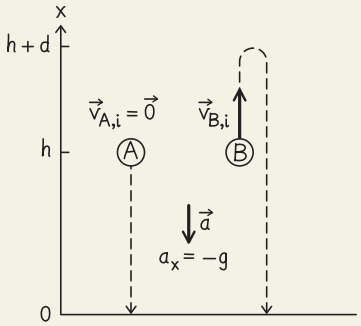
Equation 7.19 gives the change in gravitational potential energy between two positions:

$$\Delta U^G = U_f^G - U_i^G = mg(x_f - x_i) = mgx_f - mgx_i, \qquad (7.20)$$

from which we deduce that the gravitational potential energy of the Earth-object system is given by

$$U^G(x) = mgx \quad \text{(near Earth's surface)}, \qquad (7.21)$$

where x is the object's vertical coordinate with the positive x axis pointing up.



Implicit in this expression is that $U^G = 0$ at $x = 0$. Note, however, that if we write $U^G = mg(x + c)$, with c some arbitrary constant, Eq. 7.20 remains the same because the constant c, which appears in both terms, cancels out. This arbitrariness in the reference point for zero gravitational potential energy is no different from the arbitrariness in the reference point for measuring elevations or from the reference frame dependence of kinetic energy—physically, only *changes* in energy are relevant. Because of this arbitrariness, you can choose whichever reference point you like as the position where the gravitational potential energy is zero (for example, the ground at $x = 0$, as in Eq. 7.21).

EXAMPLE 7.5 Path independence of gravitational potential energy

Ball A is released from rest at a height h above the ground. Ball B is launched upward from the same height at initial speed $v_{B,i}$. The two balls have the same inertia m. Consider this motion from the instant they are released to the instant they hit the ground. (*a*) Using kinematics, show that the change in kinetic energy is the same for both balls. (*b*) Show that this change in kinetic energy is equal to the negative of the change in the gravitational potential energy of the Earth-ball system between positions $x = +h$ and $x = 0$.

❶ **GETTING STARTED** I begin by representing these two motions graphically (**Figure 7.29**). Ball A drops straight down; ball B first rises a distance d above the launch position h and then falls from a height $h + d$.

Figure 7.29

❷ **DEVISE PLAN** I can obtain the initial kinetic energies from the initial speeds, which are given. So all I need to do is calculate the final speeds using the kinematics equations for motion at constant acceleration from Chapter 3. From my sketch, I see that the x component of the acceleration of the balls is given by $a_x = -g$. For part *b* I can use Eq. 7.20 to calculate the change in gravitational potential energy.

❸ **EXECUTE PLAN** (*a*) The time interval ball A takes to fall to the ground can be obtained from Eq. 3.7:

$$\Delta x = x_f - x_i = 0 - h = v_{Ax,i}\Delta t - \tfrac{1}{2}g(\Delta t)^2$$

$$= -\tfrac{1}{2}g(\Delta t)^2$$

$$(\Delta t)^2 = \frac{2h}{g}. \qquad (1)$$

The x component of the ball's final velocity is, from Eq. 7.14, $v_{Ax,f} = v_{Ax,i} - g\Delta t = -g\Delta t$, and so, using Eq. 1, I calculate that the kinetic energy of ball A just before it strikes the ground is

$$K_{A,f} = \tfrac{1}{2}mv_{A,f}^2 = \tfrac{1}{2}m[-g\Delta t]^2 = \tfrac{1}{2}mg^2\left(\frac{2h}{g}\right) = mgh. \qquad (2)$$

Because the ball begins at rest, $K_{A,i} = 0$, and so the change in kinetic energy is $\Delta K_A = K_{A,f} - K_{A,i} = mgh$.

Equation 2 holds for any value of h. After reaching its highest position, ball B falls a distance $h + d$ to the ground, and so, substituting $h + d$ for h in Eq. 2, I obtain the final kinetic energy of ball B: $K_{B,f} = mg(h + d)$. To determine d, I examine ball B's motion from its initial position $x_i = h$ to the top of its path, where $x_f = h + d$, and again use Eq. 3.7:

$$\Delta x = (h + d) - h = d = v_{Bx,i}\Delta t_{top} - \tfrac{1}{2}g(\Delta t_{top})^2, \qquad (3)$$

but the time interval Δt_{top} required to reach the top of the trajectory is not known. I do know, however, that the ball's velocity at the top is zero, and so I can say, again using Eq. 7.14, that $v_{Bx,top} = 0 = v_{Bx,i} - g\Delta t_{top}$, or $\Delta t_{top} = v_{Bx,i}/g$. Equation 3 then becomes

$$d = v_{Bx,i}\left(\frac{v_{Bx,i}}{g}\right) - \tfrac{1}{2}g\left(\frac{v_{Bx,i}}{g}\right)^2 = \frac{v_{B,i}^2}{g} - \frac{1}{2}\frac{v_{B,i}^2}{g} = \frac{1}{2}\frac{v_{B,i}^2}{g}.$$

The final kinetic energy of ball B is thus

$$K_{B,f} = mg(h + d) = mgh + mg\left(\frac{1}{2}\frac{v_{B,i}^2}{g}\right) = mgh + \tfrac{1}{2}mv_{B,i}^2.$$

Because $K_{B,i} = \frac{1}{2}mv_{B,i}^2$ is the initial kinetic energy of ball B, the gain in kinetic energy for ball B is $\Delta K_b = K_{B,f} - K_{B,i} = mgh$, which is indeed equal to that of ball A (Eq. 2). ✔

(*b*) According to Eq. 7.20, the change in gravitational potential energy is

$$\Delta U^G = mg(x_f - x_i) = mg(0 - h) = -mgh. \checkmark$$

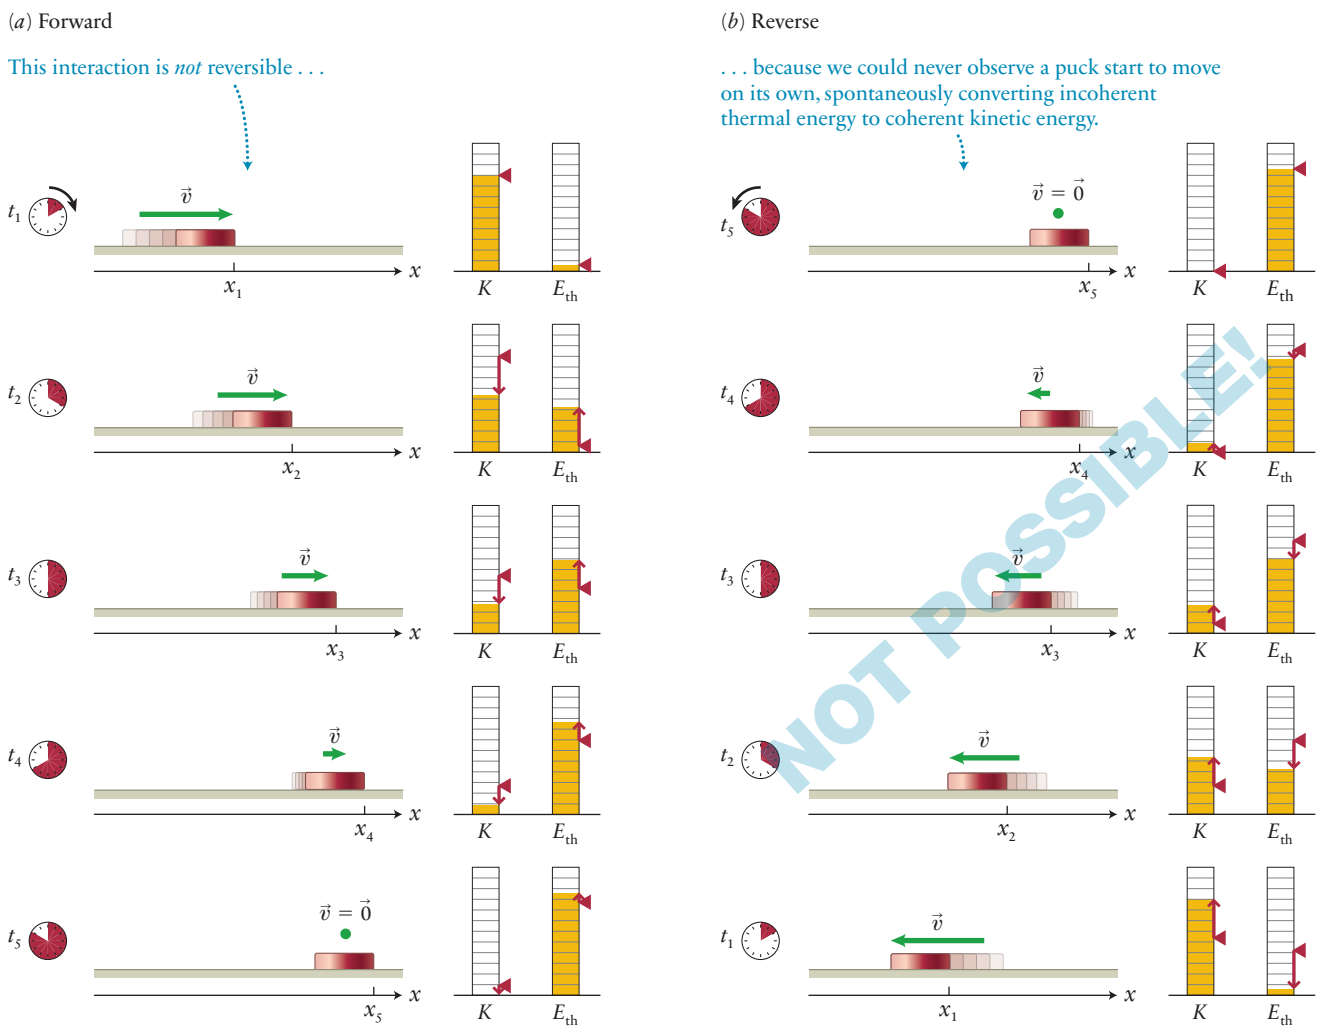
This result is equal in magnitude to the gains in the balls' kinetic energies I found in part *a*.

❹ **EVALUATE RESULT** Because I obtained the same result in two ways, I can be quite confident of my answer. My result further confirms that the change in potential energy is independent of the path taken and depends on only the endpoints of the path.

7.16 Suppose that instead of choosing Earth and the ball as our system in the discussion leading up to Eq. 7.21, we had chosen to consider just the ball. Does it make sense to speak about the gravitational potential energy of the ball (the way we speak of its kinetic energy)?

QUANTITATIVE TOOLS

7.10 Dissipative interactions



As noted in Sections 7.3 and 7.4, a dissipative interaction involves changes in thermal energy, source energy, or both. These interactions so improbable that we say they are *irreversible*. Consider **Figure 7.30*a***, which shows a puck sliding along a wooden board and slowing to a stop. The friction between the board and the puck is dissipative: If we play the sequence in reverse, we obtain an impossible situation (Figure 7.30*b*). The friction acting on the puck in Figure 7.30*a* causes its kinetic energy to be converted to thermal energy—to be dissipated. The system comprising the puck, the board, and Earth (which holds the board in place) is closed, and so Eq. 7.7, $\Delta E = \Delta K + \Delta U + \Delta E_s + \Delta E_{th} = 0$, holds. We know that ΔU is zero because there is no change in the puck's height relative to Earth and there are no springs involved. The source energy has to be zero because no nuclear or chemical reactions are involved, and so Eq. 7.7 simplifies to

$$\Delta K + \Delta E_{th} = 0. \tag{7.22}$$

Because the only kinetic energy that changes is that of the puck (the changes in the kinetic energies of the board and Earth are negligible, see Checkpoint 7.12), we can say

$$\Delta K_{puck} = -\Delta E_{th}. \tag{7.23}$$

Figure 7.30 A puck that slides to a halt (*a*) dissipates energy through friction. Because this interaction is dissipative, the process is irreversible; the sequence shown in (*b*) cannot occur.

Although this expression looks similar to Eq. 7.11, the right side is very different conceptually. In particular, thermal energy is not a function of position the way U is. The motion shown in Figure 7.30 can take place *anywhere* along the board (unlike the motion shown in Figure 7.25, which can take place only when the cart is at the spring).

Another way to see that the interaction between the puck and the board is dissipative is to look at what happens during a round trip. Imagine putting the puck down at some position x_A and then moving it back and forth between x_A and some other position x_B a dozen times. When the puck eventually returns to x_A, its state is changed: It is hotter because of the friction (and some wear has taken place). This means that energy has been dissipated irreversibly, and so $\Delta E_{th} \neq 0$ even though the puck is back at its starting position. Moving the cart of Figure 7.25 back and forth a dozen times, on the other hand, yields no change in the spring's potential energy: $\Delta U_{spring} = 0$ whenever the cart is back at its starting position.

Equation 7.7 also describes the changes in energy that take place during inelastic collisions. We know that ΔU is zero because any reversible configuration changes that occur during the first half of the collision are undone during the second half. Provided no source energy is converted during the collision, conservation of energy applied to the closed system of the colliding objects requires that the changes in kinetic energy and thermal energy add up to zero, as stated in Eq. 7.22, which we can restate in the form

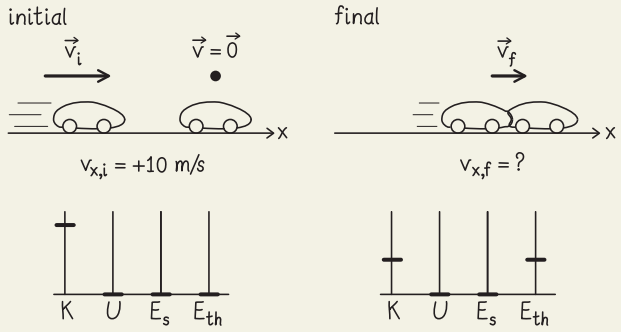
$$\Delta K = -\Delta E_{th}. \tag{7.24}$$

This equation is applicable to elastic, inelastic, and totally inelastic collisions. In elastic collisions, no energy is dissipated. Thus $\Delta E_{th} = 0$ and so Eq. 7.24 reduces to

$$\Delta K = 0 \quad (\text{elastic collision}), \tag{7.25}$$

which means that the kinetic energy of the system does not change, as we already know from Eq. 5.15. For inelastic collisions, we can compare Eq. 7.24 and Eq. 6.43, $\Delta K = \frac{1}{2}\mu v_{12i}^2 (e^2 - 1)$, where the reduced inertia μ is $m_1 m_2/(m_1 + m_2)$ and the coefficient of restitution e (Eq. 5.18) is v_{12f}/v_{12i}. This comparison tells us that the amount of kinetic energy converted to thermal energy is determined by the coefficient of restitution:

$$\Delta E_{th} = -\Delta K = \tfrac{1}{2}\mu v_{12i}^2 (1 - e^2). \tag{7.26}$$



The smaller the value of e, the larger the amount of energy dissipated from coherent energy to incoherent energy.

EXAMPLE 7.6 Fender bender

A 1000-kg car traveling at 10 m/s collides with and attaches to an identical car that is initially at rest. (*a*) How much energy is dissipated in the collision? (*b*) Use Eq. 7.26 to verify your result.

❶ **GETTING STARTED** The collision is totally inelastic, and so the kinetic energy of the two-car system after the collision is less than it was before the collision. (It has to be nonzero, however, to maintain the momentum of the isolated two-car system.) Because the system can be considered closed during the collision and because no energy is stored reversibly ($\Delta U = 0$), the kinetic energy that disappears is converted to thermal energy (the crumpling heats the metal). I make the sketch in **Figure 7.31** to represent the energy changes in the system.

Figure 7.31

QUANTITATIVE TOOLS

2 DEVISE PLAN Equation 7.24 tells me that the increase in thermal energy in the system is equal to the decrease in kinetic energy. I can determine the initial kinetic energy from the data given. To obtain the final kinetic energy, I first use conservation of momentum to calculate the velocity of the two cars immediately after impact and then calculate the kinetic energy of the combined cars.

3 EXECUTE PLAN (*a*) The initial kinetic energy is $\frac{1}{2}(1000\text{ kg}) \times (10\text{ m/s})^2 = 50\text{ kJ}$. After the collision, the cars, locked together and forming an object of inertia 2000 kg, must have the same combined momentum as the single car before the collision, and so

$$(2000\text{ kg})v_{x,\text{f}} = (1000\text{ kg})(+10\text{ m/s})$$
$$v_{x,\text{f}} = +5.0\text{ m/s}.$$

The final kinetic energy is thus

$$\tfrac{1}{2}(2000\text{ kg})(5.0\text{ m/s})^2 = 25\text{ kJ}$$

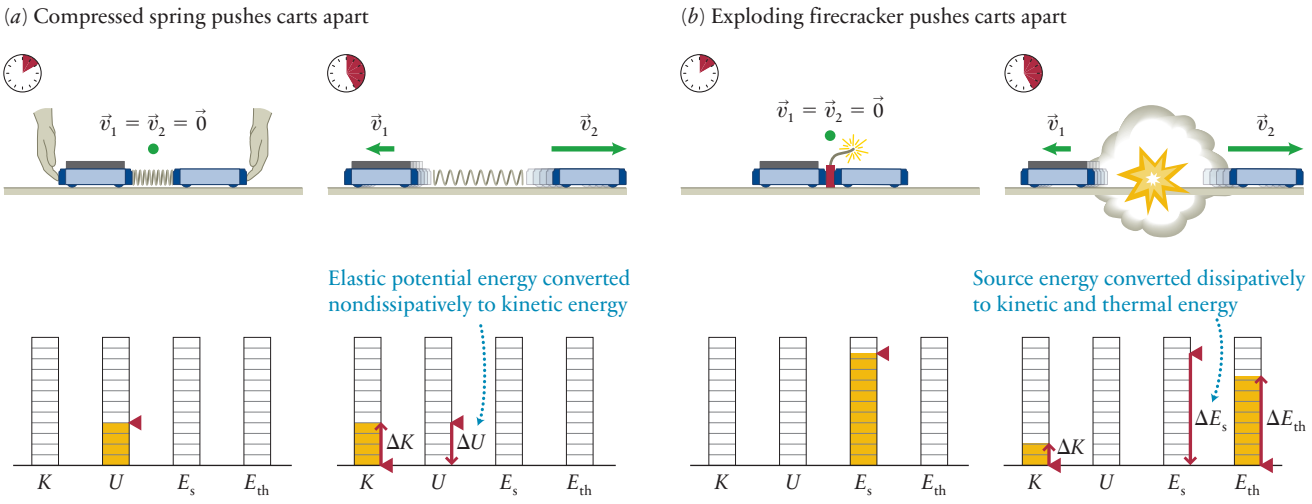
so $$\Delta K = 25\text{ kJ} - 50\text{ kJ} = -25\text{ kJ}.$$

The amount of energy dissipated is 25 kJ. ✔

(*b*) For a totally inelastic collision, $e = 0$ and Eq. 7.26 becomes

$$\Delta E_{\text{th}} = \tfrac{1}{2}\mu v_{12\text{i}}^2 = \tfrac{1}{2}\left(\frac{m_1 m_2}{m_1 + m_2}\right)v_{12\text{i}}^2 = \frac{m^2}{4m}v_{12\text{i}}^2 = \tfrac{1}{4}mv_{12\text{i}}^2,$$

where I have used the fact that the two cars have the same inertia m. The initial relative speed $v_{12\text{i}}$ is equal to the initial speed of car 1, and so $E_{\text{th}} = \frac{1}{4}(1000\text{ kg})(10\text{ m/s})^2 = 25\text{ kJ}$, as I found before. ✔



4 EVALUATE RESULT The two methods yield the same result, which is reassuring. The energy dissipated is equal to the chemical energy stored in just one-fourth of a wooden pencil (see the box on page 221), and yet both cars are likely to be wrecked beyond repair. Although it is surprising that one could wreck two cars with the chemical energy stored in one pencil, the box on page 221 states that coherent forms of energy are insignificant compared with incoherent forms, leading me to believe that the answer I obtained is not unreasonable.

As we saw in Section 5.8, a system's kinetic energy increases in an explosive separation. **Figure 7.32** shows two explosive separations. In Figure 7.32*a* the increase in kinetic energy is due to energy stored in a spring: One form of coherent energy (the elastic potential energy in the spring) is converted to another form of coherent energy (the kinetic energy of the moving carts). Because the compression of the spring is reversible, this interaction is nondissipative, and so this type of explosive separation is described by Eq. 7.8, $\Delta K + \Delta U = 0$.

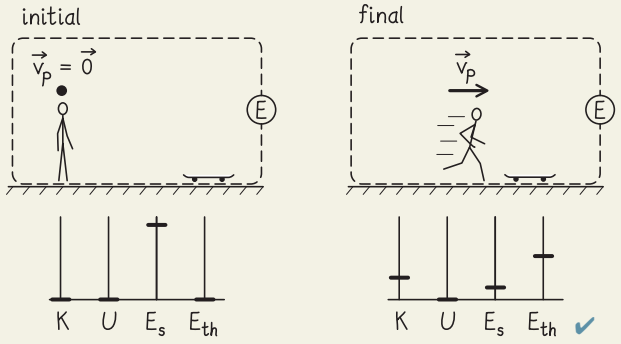
The situation in Figure 7.32*b* is irreversible. Two carts are placed back to back against a firecracker, and when the firecracker is ignited, the explosive separation accelerates the carts away from each other. There is no change in potential energy because there is no change in the cart's height relative to Earth and there are no springs involved. There is, however, a change in source energy: During the explosive separation, chemical energy is converted partly to (coherent) kinetic energy of the carts and partly to (incoherent) thermal energy (things get hot during an explosion). For this dissipative interaction, we have, with $\Delta E_{\text{s}} = \Delta E_{\text{chem}}$,

$$\Delta K + \Delta E_{\text{chem}} + \Delta E_{\text{th}} = 0. \qquad (7.27)$$

Figure 7.32 Interactions that increase the kinetic energy of a system (*a*) nondissipatively and (*b*) dissipatively.

More generally, for any interaction involving a rise in temperature, or a permanent deformation in one or more of the interacting objects, or the conversion of source energy—in short, for any dissipative interaction—we have

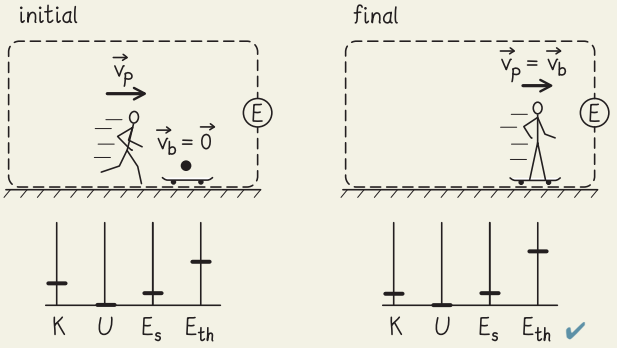
$$\Delta K + \Delta U + \Delta E_s + \Delta E_{th} = 0 \quad \text{(closed system, dissipative interaction)}. \quad (7.28)$$



In general $\Delta E_s \leq 0$ because source energy is converted to another form of energy and $\Delta E_{th} \geq 0$ because dissipation increases the amount of thermal energy.

EXERCISE 7.7 Skateboard

Standing a few meters from a skateboard, a boarder begins running and then jumps onto the board. Make bar diagrams like the ones in Figure 7.32 to illustrate the energy conversions (*a*) while he accelerates and (*b*) while he jumps onto the board. Are the interactions dissipative or nondissipative?



SOLUTION (*a*) I choose a closed system consisting of the boarder, the skateboard, and Earth. The boarder's initial kinetic energy is zero. As he accelerates during his run, he gains kinetic energy while the kinetic energy of Earth and the board remain zero. As he accelerates, he converts source energy (chemical energy extracted from food) to kinetic energy (he speeds up) and thermal energy (he gets warmer). This conversion is irreversible and therefore dissipative. There are no reversible changes in potential energy, and therefore I draw the energy bars shown in **Figure 7.33**.

Figure 7.33

(*b*) The jump onto the skateboard is a totally inelastic collision. Initially the boarder moves while the skateboard is at rest; after he lands on the board, both move at the same velocity. During this "collision," there is no conversion of source energy and no change of potential energy. As in any other totally inelastic collision, however, part of the initial kinetic energy is dissipated to thermal energy between the boarder's feet and the board and between the wheels and the ground. My bar diagram is shown in **Figure 7.34**.

Figure 7.34

7.17 How much energy is dissipated in the collision of Checkpoint 7.11?

Chapter Summary

The basics of interactions (Sections 7.1, 7.5, 7.6, 7.7)

Concepts An **interaction** is an event that produces either a physical change or a change in motion. A *repulsive interaction* causes the interacting objects to accelerate away from each other, and an *attractive interaction* causes them to accelerate toward each other.

The **interaction range** is the distance over which an interaction is appreciable. A long-range interaction has an infinite range; a short-range interaction has a finite range.

A **field** is a model used to visualize interactions between objects. According to this model, each object that takes part in an interaction produces a field in the space surrounding itself, and the fields mediate the interaction between the objects.

A **fundamental interaction** is one that cannot be explained in terms of other interactions. The four known fundamental interactions are the **gravitational interaction** (a long-range attractive interaction between objects that have *mass*), the **electromagnetic interaction** (a long-range interaction between objects that have *electrical charge;* this interaction can be either attractive or repulsive), the **weak interaction** (a short-range repulsive interaction between subatomic particles), and the **strong interaction** (a short-range interaction between *quarks,* the building blocks of protons, neutrons, and certain other subatomic particles; this interaction can be either attractive or repulsive).

Quantitative Tools If two objects of inertias m_1 and m_2 interact, the ratio of the x components of their accelerations is

$$\frac{a_{1x}}{a_{2x}} = -\frac{m_2}{m_1}. \tag{7.6}$$

Potential energy (Sections 7.2, 7.8, 7.9)

Concepts **Potential energy** is a coherent form of internal energy associated with reversible changes in the *configuration* of an object or system. Potential energy can be converted entirely to kinetic energy.

Gravitational potential energy is the potential energy associated with the relative position of objects that are interacting gravitationally.

Elastic potential energy is the potential energy associated with the reversible deformation of objects.

Changes in potential energy are *independent of path*. This means that the change in an object's potential energy as the object moves from a position x_1 to any other position x_2 depends *only* on x_1 and x_2, and *not* on the path the object takes in moving from x_1 to x_2.

Quantitative Tools The potential energy U of a system of two interacting objects can always be written in the form

$$U = U(x), \tag{7.12}$$

where $U(x)$ is a unique function of a position variable x that quantifies the configuration of the system.

Near Earth's surface, if the vertical coordinate of an object of inertia m changes by Δx, the gravitational potential energy U^G of the Earth-object system changes by

$$\Delta U^G = mg\Delta x. \tag{7.19}$$

Energy dissipation during interactions (Sections 7.3, 7.4, 7.8, 7.10)

Concepts All energy can be divided into two fundamental classes: energy associated with motion (kinetic energy) and energy associated with the configuration of interacting objects (potential energy). Each class of energy comes in two forms: *coherent* and *incoherent*. Energy is coherent if it involves ordered motion or configuration; it is incoherent if it involves random motion or configuration. For example, the kinetic energy of a moving object is coherent because all of its atoms move in the same way, whereas the thermal energy of an object is incoherent because the atoms move randomly.

The **mechanical energy** E_{mech} of a system is the sum of the system's coherent energies (kinetic energy K and potential energy U).

The **thermal energy** E_{th} of a system is the incoherent internal energy associated with the random motion of atoms that make up the objects in the system. Thermal energy cannot be entirely converted to coherent energy.

Source energy E_s is incoherent energy (such as chemical, nuclear, solar, and stored solar energy) used to produce other forms of energy.

Dissipative interactions are irreversible interactions that involve changes in thermal energy.

Nondissipative interactions are reversible interactions that convert kinetic energy to potential energy, and vice versa.

Quantitative Tools

$$E_{\text{mech}} = K + U. \tag{7.9}$$

During a dissipative interaction, the sum of the changes in all forms of energy in a closed system is zero:

$$\Delta K + \Delta U + \Delta E_s + \Delta E_{\text{th}} = 0. \tag{7.28}$$

During a nondissipative interaction, the mechanical energy of a closed system does not change:

$$\Delta E_{\text{mech}} = \Delta K + \Delta U = 0. \tag{7.8}$$

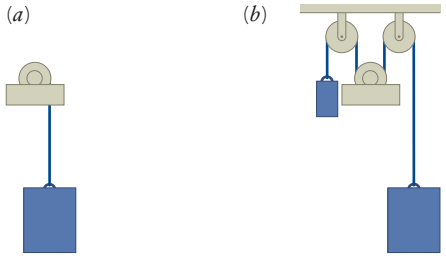
Questions and Problems

For instructor-assigned homework, go to Mastering Physics

Dots indicate difficulty level of problems: • = *easy*, •• = *intermediate*, ••• = *hard*; CR = *context-rich problem.*

7.1 The effects of interactions

1. A piece of salami is squashed between two pieces of bread. Is there one interaction between the salami and bread or more than one? •
2. Explain why you cannot cause Earth to accelerate very much, even if you jump up and down on it. •
3. Sketch curves to scale of momentum for the collision of object A initially moving with velocity v and object B initially at rest, for the following cases: (*a*) $m_A = m_B$, (*b*) $m_A = 2m_B$, (*c*) $m_A \gg m_B$. ••
4. Two objects of inertias m_1 and m_2 start from rest and then interact with each other (assume neither is interacting with any other object). (*a*) What is the ratio of their x components of velocity at any instant? (*b*) What is the ratio of their kinetic energies at any instant? ••
5. Two toy cars ($m_1 = 0.200$ kg and $m_2 = 0.250$ kg) are held together rear to rear with a compressed spring between them. When they are released, the cars are free to roll away from the ends of the spring. If you measure the acceleration of the 0.200-kg car to be 2.25 m/s^2 to the right while the spring is expanding, at that moment, what is the acceleration of the other car? ••



7.2 Potential Energy

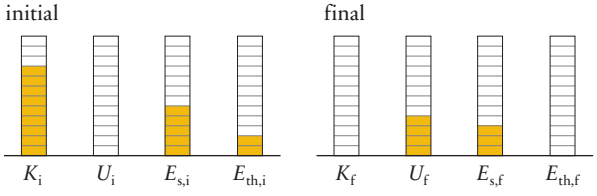
6. You are at the swimming pool and want to make a splash. You climb the ladder to the high diving board, take a big bounce, and produce a prodigious splash. Describe the changes in kinetic and potential energy involved in this motion, beginning when you start to climb and ending when you hit the water. •
7. A 1-kg block is used to compress a spring with spring constant $k = 10.0$ N/m by 5 cm, and then released. Draw energy diagrams for the spring-mass system

when the spring is (*a*) fully compressed and (*b*) fully relaxed. •

8. A ring is attached at the center of the underside of a trampoline. A sneaky teenager crawls under the trampoline and uses the ring to pull the trampoline slowly down while his 75-kg mother is sleeping on it. When he releases the trampoline, she is launched upward. As she passes through the position at which she was before her son stretched the trampoline, her speed is 3.0 m/s. How much elastic potential energy did the son add to the trampoline by pulling it down? Assume the interaction is nondissipative. ••
9. An elevator might be raised and lowered directly by a winch, as in Figure P7.9*a*, or the mechanism might include a counterweight that moves up when the elevator moves down, as in Figure P7.9*b*. In which case is the change in the gravitational potential energy of the Earth-elevator-winch system lower? ••

Figure P7.9

10. Figures 7.7 and 7.25 suggest that potential energy in a nondissipative interaction builds up and then diminishes. Is this always the case? ••
11. Two blocks are held together with a compressed spring between them on the surface of a slippery table. One block has three times the inertia of the other. When the blocks are released, the spring pushes them away from each other. What is the ratio of their kinetic energies after the release? •••



7.3 Energy dissipation

12. A trampoline's springs are what allow you to bounce, and if you bounce long enough, the springs get warm. Using Figure 7.10 as a guide, classify the energy in the springs that accounts for (*a*) the bouncing and (*b*) the heating up. (*c*) Where does this energy come from? •
13. You throw a baseball straight up, and because of air resistance some of the ball's energy is converted to thermal energy during the whole trip. Which takes longer: the trip up or the trip down? •
14. An arrow is shot into a hollow pipe resting on a horizontal table and flies out the other end. While the arrow travels in the pipe, its feathers brush against the walls of the pipe. (*a*) Which type of collision is the arrow-pipe interaction: elastic, inelastic, or totally inelastic? (*b*) Is there an instant when the velocity of the arrow relative to the pipe is necessarily zero? (*c*) Describe the energy conversions in the pipe-arrow system. ••
15. Imagine that you take a metal spring, compress it to its most compact length, and tie some string around it to keep it compressed. There is now potential energy stored in the compressed spring. You then place the tied-up spring into a container of strong acid, and, after some time, the compressed spring completely dissolves (the string is not affected by the acid). What type of energy does the compressed spring have and what is it converted to when it dissolves in the acid? ••
16. Mattresses are often a linked set of coil springs. Using Figure 7.10 as a guide, classify the energy that you give the mattress in each of these cases: (*a*) You slide the mattress from one side of a room to the other side. (*b*) You jump on the mattress several times. (*c*) You run your fingers along the tops of the coils, so that they jiggle around. (*d*) By jumping hard, you manage to snap some of the links between the coils. ••
17. Make a graph of the kinetic energy, potential energy, and incoherent energy versus time for (*a*) a moving billiard ball colliding with a stationary billiard ball, and (*b*) a moving ball of cookie dough colliding with, and sticking to, an identical but stationary ball of cookie dough. ••
18. When a steel ball and a soft rubber ball are dropped from the same height onto a concrete surface, the steel ball bounces higher. When they are dropped onto packed sand, however, the rubber ball bounces higher. Explain the difference. •••

7.4 Source energy

19. Choose an appropriate closed system and draw a bar diagram representing the energy conversions and transfers that occur during each process of Checkpoint 7.9: (*a*) a ball launching as the compressed spring it sits on expands, (*b*) a ball released from some height and falling to the ground, (*c*) a coasting bicycle slowing down, (*d*) a car accelerating on a highway. •
20. A 2000-kg car burns gasoline with 25% efficiency. Accelerating from rest, how fast would this car go upon burning 0.040 L of gasoline if 1.0 L of gasoline contains approximately 3.2×10^7 J of energy? ••
21. (*a*) Figure P7.21 shows initial and final energy bars for a closed system. Adjust the height of any two energy bars in the final version, on the right, so that the diagram does not violate what we know about energy. (There are numerous ways for you to do this.) (*b*) Describe an interaction that would generate an energy bar diagram that matches your version of Figure P7.21. ••

Figure P7.21

22. Two objects initially moving at velocities that have x components v_{1x} and v_{2x} collide totally inelastically. (*a*) Show that the ratio of the kinetic energy dissipated in the interaction is

$$\frac{\Delta K_1}{\Delta K_2} = -\frac{v_{\text{cm}x} + v_{1x,\text{i}}}{v_{\text{cm}x} + v_{2x,\text{i}}}.$$

(*b*) What does the minus sign in the expression in part *a* mean? ●●

7.5 Interaction range

23. If, on the atomic scale, "contact" between two objects is in fact not *physical* contact, does that have implications for the contact between atoms in a piece of copper? ●
24. Look again at Checkpoint 7.10. Suppose you and a friend stand within an arm's length of each other and throw a ball back and forth. Describe a method to model an attractive interaction based on throwing the ball. ●●
25. Look again at Checkpoint 7.10. (*a*) When you throw a ball to a friend, at what instant does your momentum change: at the beginning, middle, or end of the ball's flight? (*b*) At which of these three instants does your friend's momentum change? ●●
26. Give three examples to support the statement "long-range interaction forms the underlying basis for most life processes and technology." ●●

7.6 Fundamental interactions

27. Suppose that, instead of two types of electrically charged particles in the universe, there was only one type. What would you expect to happen to the structure of the universe if the particles produced (*a*) an attractive interaction and (*b*) a repulsive interaction? ●
28. Explain why tension (in ropes, etc.) and the contact forces between surfaces are not fundamental forces. ●
29. Suppose that the range of the strong interaction were suddenly increased by 20 orders of magnitude, with all other interactions unchanged. Describe the changes that might occur in the structure of our world. ●●
30. Picture two objects, A and B, taking part in some interaction involving gauge particles. If object A radiates gauge particles uniformly in all directions, how does the strength of the interaction depend on the distance from A to B? Assume that the gauge particles do not interact with one another and that the strength of the interaction is proportional to the number of gauge particles encountered by B. ●●●

7.7 Interactions and accelerations

31. On a low-friction track, a 1.7-kg cart initially going at 2.8 m/s to the right collides with a cart of unknown mass initially going at 1.2 m/s to the left. After the collision, both of the carts move to the right with the 1.7-kg cart at 2.0 m/s and the cart of unknown mass at 5.9 m/s. The collision takes 0.050 s. (*a*) Calculate the unknown mass. (*b*) Calculate the average acceleration of each cart. (*c*) Use your answer to part *a* to check your answer to part *b*. ●
32. Two children on ice skates pull toward each other on a rope held taut between them. The inertia of one child is 30 kg, and the inertia of the other is 25 kg. (*a*) If at one instant the 30-kg child is accelerating at 1.0 m/s^2 to the left, what is the acceleration of the 25-kg child at that instant? (*b*) What happens to each acceleration if the 25-kg child stops pulling and just hangs on? ●
33. A 0.010-kg bullet is fired from a 5.0-kg gun with a muzzle velocity of 250 m/s. (*a*) While the bullet is traveling in the barrel, what is the ratio of the acceleration of the gun to the acceleration of the bullet as a function of time? (*b*) What is the speed of the bullet relative to the ground at the instant the bullet leaves the barrel? (*c*) What is the speed of the gun relative to the ground at that instant? ●●
34. A 1500-kg car going at 6.32 m/s collides with a 3000-kg truck at rest. If the collision is totally inelastic and takes place over an interval of 0.203 s, what is the average acceleration of each vehicle? Are the ratio of accelerations and the ratio of inertias related the way you expect them to be? ●●
35. A glob of putty thrown to the right bounces off a 0.500-kg cart initially at rest on a low-friction track. The collision takes 0.15 s, and the coefficient of restitution is 0.64. The cart has a final velocity of 1.0 m/s to the right, and the glob has a final velocity of 0.834 m/s to the left. (*a*) What is the inertia of the glob? (*b*) What is the average acceleration of each object during the collision? ●●
36. An 8.20-kg object is sliding across the ice at 2.34 m/s. An internal explosion occurs, splitting the object into two equal chunks and adding 16 J of kinetic energy to the system. What is the average acceleration of the two chunks if the explosive separation takes place over a 0.16-s time interval? ●●
37. A railroad car that has an inertia of 5.04×10^4 kg is moving to the right at 4.25 m/s when it collides and couples with three identical railroad cars that are already coupled together and moving in the same direction at 2.09 m/s. If the acceleration of the single car is 5.45 m/s^2 to the left while it is changing velocity, how long does the interaction take? ●●
38. A 90-kg halfback on a football team runs head-on into a 120-kg opponent at an instant when neither has his feet on the ground. The halfback is initially going west at 10 m/s, and his opponent is initially going east at 4.37 m/s. The collision is totally inelastic. (*a*) If the collision takes 0.207 s, what is the acceleration of each player? (*b*) How much kinetic energy is converted to incoherent energy during the collision? ●●
39. You are watching a hockey game on your digital video recorder. Your team's goalie is at rest when he catches a 0.16-kg puck moving straight toward him. The announcer says it was a 40-m/s slap shot, based on radar gun data. Normally the goalie would be braced, but in this case he is resting on parallel skate blades so that there is negligible friction to impede his subsequent motion. The collision is too fast to observe quantitatively, but by running the video in slow motion, you can tell that the goalie's glove is 150 mm from his body when

the puck strikes and is right against his chest after the successful catch. It is also clear that the stunned goalie (holding the puck) drifts backward at 71 mm/s for a second or two after the collision is over. (*a*) Compute the average acceleration of the puck and of the goalie during the collision. (*b*) Determine the inertia of the goalie (including his equipment). (*c*) How much kinetic energy is converted to thermal energy in the glove? Check your answers by solving in two ways when possible. •••

40. Two objects, one red and one yellow, start from rest and interact with each other along an x axis. (*a*) If $m_{red} < m_{yellow}$, what are the ratios of their changes in momentum, velocity, and kinetic energy? (*b*) Compare these ratios with the ratio of their accelerations. (*c*) What does your answer to part *a* tell you about the relative changes of these quantities for a ball and Earth when you drop the ball? •••

7.8 Nondissipative interactions

41. Draw a bar diagram representing the various kinds of energy for the cart-spring system in Figure 7.26*b* when the end of the cart attached to the spring is at locations x_1, x_2, and x_3. •

42. The potential energy of an interaction is given by $U(x) = ax^2$, where $a = +6.4\ \text{J/m}^2$. (*a*) If the initial speed of a 0.82-kg object in this system is 2.23 m/s at $x = 0$, how far does the object travel before it reaches a speed of $v = 0$? (*b*) Does your answer in part *a* depend on whether the object is traveling in the positive or negative x direction? •

43. Suppose we have a block mounted on a spring and define the zero point for the elastic potential energy of the system to be the relaxed position (meaning the block is positioned such that the spring is neither compressed nor stretched). What is the appropriate sign of the elastic potential energy when the block is repositioned so that the spring is (*a*) stretched and (*b*) compressed? (Hint: Think about what happens to the elastic potential energy when the stretched or compressed spring is released.) ••

44. A 0.36-kg cart and a 0.12-kg cart are held together with a compressed spring between them. When they are released, the 0.36-kg cart moves at 1.1 m/s to the right. How much elastic potential energy was stored in the spring before the release? ••

45. A 0.530-kg cart moving at 0.922 m/s to the right collides elastically with a 0.25-kg cart initially at rest. The 0.25-kg cart then moves off rapidly and compresses a spring before the 0.530-kg cart can catch it again. At the instant the 0.25-kg cart comes to rest, what is the energy stored in the spring? ••

46. A low-friction track is set up with a spring on the right end. In the middle of the track, a 2.0-kg cart moving to the right at 5.0 m/s overtakes a 3.0-kg cart moving to the right at 2.0 m/s. After the collision, the 2.0-kg cart is moving at 1.7 m/s. (*a*) What is the coefficient of restitution of the collision? (*b*) How much energy is stored in the spring when it is at its maximum compression after the collision? ••

47. A 5-kg object is subject to an interaction that has a potential energy $U(x) = \frac{1}{2}kx^2 - bx$, where $k = 2.0\ \text{J/m}^2$ and $b = 1.5\ \text{J/m}$. At $x = 1.0$ m, the object is found to be moving to the left at 4 m/s. What is the speed of the object at $x = 2.0$ m? What is the object's kinetic energy at $x = 3.0$ m? ••

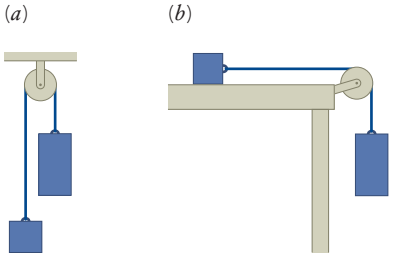
48. You release a block from the top of a long, slippery inclined plane of length ℓ that makes an angle θ with the horizontal. The magnitude of the block's acceleration is $g \sin\theta$ (see Section 3.7). (*a*) For an x axis pointing down the incline and having its origin at the release position, derive an expression for the potential energy of the block-Earth system as a function of x. (*b*) How would your expression change if you put the origin of the x axis at the bottom of the incline? (*c*) Does the location of the origin make any difference in the dynamics of the situation? (*d*) Use the expression you derived in part *a* to determine the speed of the block at the bottom of the incline. Does your speed value agree with the result obtained by a kinematic calculation? •••

49. On a low-friction track, a 0.36-kg cart initially moving to the right at 2.05 m/s collides elastically with a 0.12-kg cart initially moving to the left at 0.13 m/s. The 0.12-kg cart bounces off the 0.36-kg cart and then compresses a spring attached to the right end of the track. (*a*) At the instant of maximum compression of the spring, how much elastic potential energy is stored in the spring? (*b*) If the spring then returns all of this energy to the cart, and the two carts again collide, what is the final velocity of each cart? •••

7.9 Potential energy near Earth's surface

50. A rock climber accidentally drops a 4.5-kg backpack, and it falls 160 m to the ground below. What is the change in the gravitational potential energy of the system comprising the backpack and the Earth? •

51. At graduation, you toss your mortarboard cap straight up at some initial speed v. How fast is it moving when it comes back down to your hands if you (*a*) ignore air resistance and (*b*) include it? How do you know? •



52. An office worker has his lunch on the 53rd floor of an office building. In which case is the gravitational potential energy of the lunch-Earth system greatest: (*a*) the worker carried the lunch up to the 53rd floor in the elevator, (*b*) he carried it up the stairs to the 53rd floor, or (*c*) he got a ride in a helicopter to the top of the 68-floor building and then carried the lunch down in the elevator to the 53rd floor? •

53. The fastest baseball pitchers can throw the 0.145-kg ball at speeds of about 45 m/s. Ignoring air resistance, what height must the ball be dropped from to hit the ground at this speed? •

54. A typical loaded commercial jet airplane has an inertia of 2.1×10^5 kg. (*a*) Based on the time intervals involved, which do you expect to require more energy: getting the plane up to cruising speed or getting it up to cruising altitude? (*b*) How much energy does it take to get the plane to a cruising speed of 270 m/s? (Ignore wind drag.) (*c*) How much energy does it take to get the plane to a cruising altitude of 10,400 m if it travels to that altitude at its (constant) cruising speed? ••

55. Two 2.4-kg blocks are connected by a string draped over the edge of a slippery table, so that one block is on the table and the other is just hanging off the edge. A restraint holds the block on the table in place, and the string is 0.50 m long. After the restraint is removed, what speed does the pair of blocks have at the instant the upper one is pulled off the table? ●●
56. A 30-kg child jumps to the ground from the top of a fence that is 2.0 m high. You analyze the problem using upward as the positive x direction. (*a*) Taking $x = 0$ to be at the bottom of the fence, what are the initial potential energy of the child-Earth system and the change in the system kinetic energy during the jump? (*b*) Repeat part *a* for $x = 0$ at the top of the fence. ●●
57. You lean out of your dorm window, which is 12 m above the ground, and toss a 0.12-kg ball up to a friend at a window 11 m above you. (*a*) What is the slowest initial speed at which you can throw the ball so that he just catches it? (*b*) If you throw the ball at this speed and your friend misses it, what is its kinetic energy the instant before it hits the ground? (*c*) Suppose you throw the ball directly downward at the speed calculated in part *a*. What is its kinetic energy just before it hits the ground? ●●
58. Two blocks are hung by a string draped over a pulley, a 1.0-kg block on the left and a 3.0-kg block on the right. The two blocks start out at rest and at the same height. (*a*) What is the change in the gravitational potential energy of the system of blocks and Earth when the 3.0-kg block has dropped 0.53 m? (*b*) What is the change in the kinetic energy of the system between release and this instant? (*c*) What is the velocity of the 1.0-kg block at this instant? ●●
59. You drop a rubber ball from a height of 3.0 m. It bounces off a concrete surface to a height of 2.7 m. (*a*) What is the coefficient of restitution for this collision? (*b*) You want to get the ball to bounce upward to a height of 7.3 m. From the same starting point, how fast must you throw the ball, and in which direction? ●●
60. A 100-g apple is dropped from a height of 12 m and 1 second later is struck by a 100-g arrow flying upward at 15 m/s. (*a*) What is the speed of the apple and the arrow just after collision? (*b*) How much energy is lost in the collision? (*c*) How long does it take the combined object to reach the ground from the time the apple was dropped? ●●
61. A uniform chain of inertia m and length ℓ is lying on a slippery table. When one quarter of its length hangs over the edge, the chain begins to slip off. How fast is it moving when the last bit of it slips off the table? (Ignore friction.) ●●●
62. A uniform chain of inertia m and length ℓ is lying on a slippery table. When just the tip hangs over the edge, the chain begins to slip off. (Ignore friction.) Calculate the speed of the chain as a function of time. (Hint: $\int \frac{dx}{v} = \int dt$. What's the connection between x and v?) ●●●
63. Two blocks are connected by a string draped over a small pulley. The smaller block has half the inertia of the larger block. For which configuration, (*a*) or (*b*), in Figure P7.63 are the speeds of the blocks greatest after the larger block has descended a distance d? Ignore friction between the table and the sliding block, and check your answer with a computation. ●●●

Figure P7.63

7.10 Dissipative interactions

64. Gravity-powered roller coasters have a motorized chain assembly that hauls the cars up to the top of the first hill. No additional source energy is supplied for the rest of the trip. What is the maximum possible height for all subsequent hills? ●
65. While you are standing on your balcony 8 m above the ground, your friend tosses a 0.4-kg book at you from the ground at 14 m/s. The book barely makes it to your hand. How much energy was dissipated by air resistance? ●
66. A 5.3-kg steel ball is dropped from a height of 20 m into a box of sand and sinks 0.20 m into the sand before stopping. How much energy is dissipated through the interaction with the sand? ●●
67. Two cars collide inelastically on a city street. For the two-car system, which of the following are the same in any inertial reference frame: (*a*) the kinetic energy, (*b*) the momentum, (*c*) the amount of energy dissipated, (*d*) the momentum exchanged? ●●
68. A 0.70-kg basketball dropped on a hardwood floor rises back up to 65% of its original height. (*a*) If the basketball is dropped from a height of 1.5 m, how much energy is dissipated in the first bounce? (*b*) How much energy is dissipated in the fourth bounce? (*c*) To which type of incoherent energy is the dissipated energy converted? ●●
69. In a simple throwball game on ice, a 90-kg athlete throws a 1.0-kg ball at 15 m/s. The ball is caught by his 80-kg teammate. If 20% of the source energy is lost in the initial throw, then what are the recoil speeds of the athletes? What is the source energy? ●●
70. A 2.2-kg measuring instrument is mounted on a balloon by your scientific team for atmospheric studies. At the top of its flight, the instrument is released from the balloon and falls most of the way back to Earth before a parachute opens. You are told that the magnitude of the acceleration at any instant t before the parachute opens is given by $|a| = ge^{-t/\tau}$, where g is the acceleration due to gravity, e is the base of natural logarithms, and τ is a time constant that depends on the shape of the instrument and in this case is 5.68 s. Your primary concern is how much the instrument heats up as it falls, due to air

resistance. At what rate, in joules per second, is energy dissipated before the parachute opens? Express your answer as a function of t, where $t = 0$ at release. (Hint: Integrate the acceleration to calculate speed and displacement.) •••

71. A nursery rhyme goes "Humpty Dumpty sat on a wall, Humpty Dumpty had a great fall. All the king's horses and all the king's men couldn't put Humpty Dumpty together again." (*a*) Describe the energy of the Earth-HD system before, during (including the instant just before impact), and after the fall. Use bar diagrams showing K, U, E_s, and E_{th} to illustrate your description. (*b*) In terms of the energy of the Earth-HD system, explain why all the king's horses and all the king's men could not put HD together again. (*c*) Now assume that things had turned out differently for HD. The king's men were able to set up a net so that he fell into the net and bounced back up and once again sat on the wall. Draw energy bar diagrams for this situation, showing the distribution of energy during the fall, at the instant HD arrives at the net (choose the instant at which the net with HD in it is stretched to the lowest position), during the ascent, and when he is back sitting on the wall. •••

72. A small block of wood of inertia m_{block} is released from rest a distance h above the ground, directly above your head. You decide to shoot it with your pellet gun, which fires a pellet of inertia m_{pellet}. After the block has fallen a distance d, the pellet hits it and becomes embedded in it, kicking it upward. At the instant of impact, the pellet is moving at speed v_{pellet}. (*a*) To what maximum height h_{max} does the pellet-block system rise above the ground? Express your answer in terms of the given variables and known values, such as g. (*b*) How much energy is dissipated in the collision? •••

Additional Problems

73. Is the collision between two billiard balls a nondissipative interaction? (Hint: What does the fact that you can hear the collision tell you?) •

74. Draw before and after energy bars for the collision shown in Figure 6.8*a* and 6.8*b*. •

75. A 60-g Mars bar will supply you with 1095 kJ of energy. How many of them would you need to get enough energy to climb the first 800 m of the highest structure in the world? The next 800 m? Assume your inertia to be 80 kg. •

76. You drop a ball from some height. At which position do you expect its speed to be one-half the speed at which it eventually hits the ground: higher than the midpoint of the path, at the midpoint, or lower than the midpoint? Does air resistance change your answer? ••

77. Is it impossible to convert incoherent energy to coherent energy? Can you think of an example where thermal energy can (at least partially) be converted to coherent energy? ••

78. People unenlightened about physics sometimes fire a gun straight up into the air to celebrate big events. By discussing the forms of energy at each stage of the process, explain why this is a bad idea. ••

79. A 1-kg cart and a 2-kg cart are held together with a coupler that contains a small charge. The charge is exploded and sends the 1-kg cart rolling away at +4.0 m/s. What is the speed of the 2-kg cart? How much energy does the explosion create if 70% of it is lost as heat? ••

80. Wind turns a windmill that stores energy in a battery. Assume that the windmill turns at a constant rate while the battery is charging. The battery is then used to run a toy car that moves at a constant speed until the battery goes dead. Draw bar diagrams representing a sequence of instants that depict the various conversions of energy from one form to another in this situation. For each conversion, name the system you are describing. ••

81. You and your bike collide at 12 m/s into the back of a car stopped at a red light. The car does not have its brakes applied and so is jolted forward. The driver immediately leaps out crying, "Whiplash!" Facing a day in court, you have to determine the acceleration of the car as a result of the collision. You note that you and your bike (combined inertia 80 kg) came to a complete halt in the collision and that the rim of your front wheel was pushed all the way to the center hub—the same distance the car traveled during the crash. The diameter of the bike wheel before the crash was 0.75 m, and the car's inertia is 1800 kg. ••• CR

82. An amusement park commissions your company to design a roller coaster. Your company specializes in an approach in which the cars are accelerated on a horizontal section of track by magnetic motors rather than being hauled up to the top of a hill and released. The park officials would like the riders to be accelerated via your horizontal design and then sent straight up a vertical length of track 66.4 m tall. (After the cars pass this high point, the ride is the regular ups and downs of a conventional roller coaster.) Your calculations tell you that 212 motors will get the loaded cars up to the necessary speed at an acceleration of $0.85g$, but you wonder whether or not the park has enough horizontal distance available for the acceleration device. ••• CR

83. A 1.00-kg cart has attached to its front end a device that explodes when it hits anything, releasing a quantity of energy E. This cart is moving to the right with speed v when it collides head-on with a 2.00-kg cart traveling to the left at the same speed v. The explosive goes off when the carts hit, causing them to rebound from each other. If one-quarter of the explosive energy is dissipated into the incoherent energy of noise and deformation of the carts, what is the final velocity of each cart? Solve in the zero-momentum reference frame and then check your result by solving in the Earth reference frame. •••

8.9 Hooke's law
8.10 Impulse
8.11 Systems of two interacting objects
8.12 Systems of many interacting objects

At this point in your study of physics, you can already solve a wide range of problems using just the conservation laws. Up to now we have applied these laws in only isolated or closed systems, however, and it is not always possible to identify such a system when working on problems. For this reason, you also need to know an approach to problem solving that is valid in systems that are interacting with their surroundings. If you look back at the material in earlier chapters, you will notice that many of the interactions we discussed involve pushing, pulling, or rubbing—all actions related to the everyday notion of *force*. So, in order to be able to deal with systems that are not isolated, you must know about the concept of force.

The term *force* is a familiar one—usually associated with the capacity to change the motion, or non-motion, of objects (for example, pushing a chair along the floor) or to cause physical change (say, crushing an empty can). To which of the physical quantities I have defined so far does this notion of force best correspond, however, and how can we quantify it?

8.1 Momentum and force

To relate the intuitive concept of force to the quantities we have encountered so far, consider the following scenario. You are on a bicycle coming down a steep hill and approaching a sharp turn at 30 km/h. Suddenly you discover that your brakes are not working, leaving you no option but to slam into a concrete wall. The force of impact will be considerable, and if you were going faster—say, 40 km/h—it would be even greater. Conversely, if you were going at a mere 3 km/h, the impact might not be that bad. And it is not just your speed that matters. When you are carrying a backpack full of bricks and traveling at 30 km/h, the force of impact is greater than when you are traveling at the same speed but carrying nothing on your back.

Realizing that both your speed and your inertia govern the force of the impact you make with the wall, you may be tempted to believe that force is related solely to change in momentum, but things are not that simple. To see why, imagine that part of the concrete wall is padded with mattresses. Which part do you head for? You don't need any physics to realize that the mattresses offer you protection. When you hit a mattress, the force of impact is smaller than when you hit the concrete. In terms of momentum change and energy change, however, it doesn't make any difference which one you choose. In either case, your speed decreases by the same amount, 30 km/h, and so the decreases in your momentum and kinetic energy are the same no matter how you come to a stop.

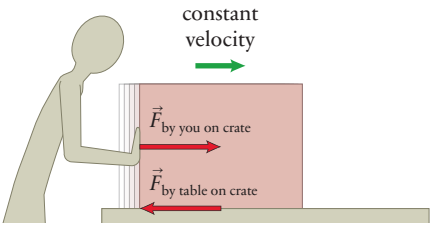
The difference between hitting a mattress and hitting the concrete is that the mattress changes your momentum over a longer time interval. The momentum change therefore occurs at a slower rate. Evidently, the longer the interaction time interval, the smaller the force of impact. In other words, what determines the magnitude of the force of impact is not the absolute value of your momentum change but rather the rate at which this change happens. The faster your momentum changes, the larger the force of the impact on you.

This scenario illustrates two important points about forces. First, forces are manifestations of interactions—the force exerted by the mattress on you, for example, is one part of the interaction between you and the mattress (another part is the force exerted by you on the mattress). Second, for an object that is participating in one interaction only, we can quantitatively define **force:**

> **The force exerted on the object is the time rate of change in the object's momentum.**

Because it is related to a change in momentum, force is a vector and so has direction as well as magnitude. The direction of any given force is the same as the direction of the momentum change the force causes. When you hit the wall in our bicycling example, for instance, the direction of the force exerted by the wall on you is opposite your direction of travel because the direction of your momentum change is opposite your direction of travel.

Even though the arguments leading up to the relationship between force and time rate of change in momentum all sound very plausible, I should warn you that the consequences of this relationship differ from your intuitive notions about forces in a number of ways.



CONCEPTS

8.1 Imagine pushing a crate in a straight line along a surface at a steady speed of 1 m/s. What is the time rate of change in the momentum of the crate?

The answer to this checkpoint should surprise you. After all, you *are* pushing the crate. So how can the time rate of change in the momentum of the crate be zero? The problem here is that the crate is interacting not just with you but also with the surface because there is friction between it and the surface. The directions and magnitudes of these two interactions (between the crate and your hands and between the crate and the surface) are such that their combined action causes no change in the momentum of the crate, and so it continues to move at constant speed in the direction of your push. In each interaction, there is a force exerted on the crate—exerted by you in one case and by the surface in the other case. The force exerted by your hands on the crate tends to move the crate

Figure 8.1 When you push a crate along a surface, two opposing forces are exerted on the crate: one by you (the push), the other by the surface (friction). If these forces are equal in magnitude, the crate moves at constant velocity.

forward, while the force exerted in the horizontal direction by the surface on the crate (the *force of friction* or *frictional force*) tends to resist the forward motion of the crate. If the two opposing forces exerted on the crate are equal in magnitude, their vector sum (sometimes called the *net force*) is zero. In other words, if the surface pushes on the crate just as hard as you push on it in the opposite direction, the acceleration effects of the two opposing forces cancel and the crate moves at constant velocity (**Figure 8.1**). If the force exerted by the surface on the crate is smaller than the force you exert on it, the crate speeds up; if the force exerted by the surface is larger, the crate slows down.

For an object A interacting with more than one other object (such as a crate interacting both with you and with the surface), the resulting effect on A's momentum is due to the combined action of a number of forces, one for each interaction. Experimentally, we discover that forces obey the *principle of superposition*: The vector sum of the forces exerted on A is equal to the vector sum of the rate of change caused in A's momentum by the individual forces. Consequently:

The vector sum of all forces exerted on an object equals the time rate of change in the momentum of the object.

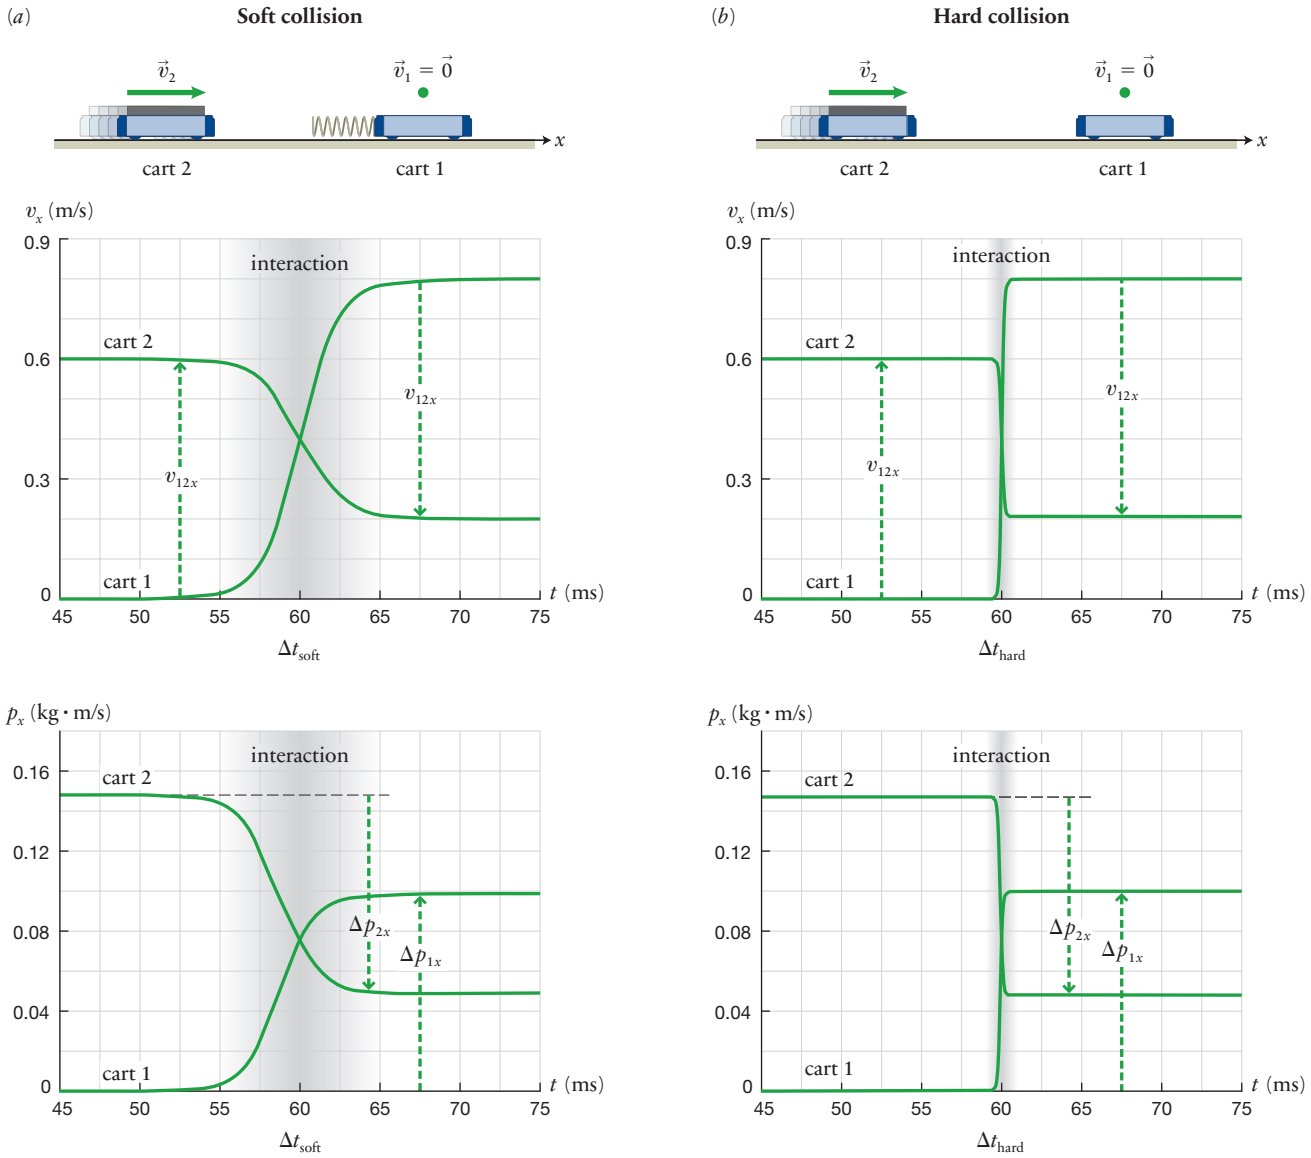
CONCEPTS

For an object of fixed inertia, a change in momentum implies a change in velocity. So, when the vector sum of the forces exerted on an object is not zero, the object has a nonzero acceleration. The vector sum of the forces exerted on an object points in the same direction as the object's acceleration.

8.2 Imagine pushing on a crate initially at rest so that it begins to move along a floor. (*a*) While you are setting the crate in motion, increasing its speed in the desired direction of travel, what is the direction of the vector sum of the forces exerted on it? (*b*) Suppose you suddenly stop pushing and the crate slows to a stop. While the crate slows down, what is the direction of the vector sum of the forces exerted on it? (*c*) What is the direction of the vector sum of the forces once the crate comes to rest?

8.2 The reciprocity of forces

Another surprising aspect of the definition of force is that, because of the reciprocal nature of interactions, forces always come in pairs: When two objects interact, each exerts a force on the other. To see this, consider **Figure 8.2**, which illustrates two elastic collisions. In both collisions, cart 1 of inertia $m_1 = 0.12\ \text{kg}$ is initially at rest and cart 2 of inertia $m_2 = 0.24\ \text{kg}$ is initially moving at 0.60 m/s. For both collisions, the final velocity of cart 1 is 0.80 m/s and that of cart 2 is 0.20 m/s. The only difference between the two collisions is that in Figure 8.2*a* the impact is softened by a spring, much like the cushioning of a fall by a mattress. As we did before, during the collision, we can ignore all interactions except that between the two carts.



8.3 (*a*) Verify that for both collisions in Figure 8.2 the momentum of the two-cart system remains constant. (*b*) Verify that both collisions are elastic.

As this checkpoint shows, in both collisions the momentum change of cart 1 is compensated for by an opposite change in the momentum of cart 2. Let's now relate these momentum changes to forces. For the soft collision, the changes in momentum take place during a time interval Δt_{soft} (about 10 ms). During this time interval, the x component of the momentum of cart 1 changes by an amount $\Delta p_{1x} = +0.096\ \text{kg}\cdot\text{m/s}$. Because force equals time rate of change in momentum, the x component of the average force exerted by cart 2 on cart 1 during the time interval Δt_{soft} is $(F_{\text{by 2 on 1}})_x = \Delta p_{1x}/\Delta t_{\text{soft}} = (+0.096\ \text{kg}\cdot\text{m/s})/(0.010\ \text{s}) = +9.6\ \text{kg}\cdot\text{m/s}^2$.

Because the two-cart system is isolated, the change in the momentum of cart 2 must be equal in magnitude to that of cart 1 and in the opposite direction, and so $\Delta p_{2x} = -0.096\ \text{kg}\cdot\text{m/s}$. Because the time interval it takes for this change to occur is also Δt_{soft}, we calculate for the x component of the time rate of change in the momentum of cart 2, $(F_{\text{by 1 on 2}})_x = \Delta p_{2x}/\Delta t_{\text{soft}} = -9.6\ \text{kg}\cdot\text{m/s}^2$. In words, the force exerted by cart 1 on cart 2 is equal in magnitude to the force exerted by cart 2 on cart 1 and in the opposite direction.

For the hard collision in Figure 8.2*b*, the momentum changes are the same as for the soft collision, but now the time interval during which these changes take place is much shorter, $\Delta t_{\text{hard}} \approx 1.0$ ms. As you might expect, the forces are much larger: For cart 1, we now have $(F_{\text{by 2 on 1}})_x = \Delta p_{1x}/\Delta t_{\text{hard}} = (+0.096\ \text{kg}\cdot\text{m/s})/(0.0010\ \text{s}) = +96\ \text{kg}\cdot\text{m/s}^2$. The force exerted by cart 2 on cart 1 is again equal in magnitude to the force exerted by cart 1 on cart 2 and in the opposite direction because the two-cart system is isolated: $\Delta p_{1x} = -\Delta p_{2x}$. Now $(F_{\text{by 1 on 2}})_x = \Delta p_{2x}/\Delta t_{\text{hard}} = -96\ \text{kg}\cdot\text{m/s}^2$. So we conclude:

Figure 8.2 (*a*) Soft and (*b*) hard collisions between two carts on a low-friction track. The inertias are $m_1 = 0.12$ kg and $m_2 = 0.24$ kg.

Whenever two objects interact, they exert on each other forces that are equal in magnitude but opposite in direction.

The pair of forces that two interacting objects exert on each other is called an **interaction pair.**

8.4 Does the conclusion just stated apply to inelastic collisions?

8.5 If you drop a book from a certain height, it falls (accelerating all the while) because of the gravitational force exerted by Earth on it. Because forces always come in interaction pairs, the book must exert a force on Earth. (*a*) How does the magnitude of $F_{\text{by book on Earth}}$ compare with the magnitude of $F_{\text{by Earth on book}}$? (*b*) Is Earth accelerating during the interaction? Why or why not?

The conclusion that interacting objects exert equal forces in opposite directions on each other is a direct result of the law of conservation of momentum and of our definition of force. This reciprocity of forces means, for instance, that if you push a crate along the floor, the crate pushes back on you with a force of equal magnitude. Can an inanimate object like a crate exert a force, and, if so, how do we know this force exists?

Let's settle the first question first, using the concrete wall of our earlier example. Even though the wall is inanimate, there is no denying it exerts a force on you when you slam into it. I don't recommend trying it, but you can imagine feeling this force. So inanimate objects can exert forces.

Now for the second question: How do we know the crate exerts a force on you when you push it? To see

CONCEPTS

that objects push back when you push on them, imagine leaning against a door when someone suddenly opens it away from you—you tumble into the door opening precisely because the force exerted by the door on you (a force that was keeping you upright) is suddenly removed. The force exerted by you on the door and the force exerted by the door on you form an *interaction pair*.

Here is another example: Imagine tipping over a chair by kicking it with your bare foot. The chair is tipped over by the force exerted by your foot on it. Your foot hurts because of the other half of the interaction pair—the force exerted by the chair on your foot.

EXAMPLE 8.1 Splat!

A mosquito splatters onto the windshield of a moving bus and sticks to the glass. (*a*) During the collision, is the magnitude of the change in the mosquito's momentum smaller than, larger than, or equal to the magnitude of the change in the bus's momentum? (*b*) During the collision, is the magnitude of the average force exerted by the bus on the mosquito smaller than, larger than, or equal to the magnitude of the average force exerted by the mosquito on the bus?

❶ **GETTING STARTED** Because the mosquito sticks to the windshield, the bus and mosquito move together after impact and so this event is a totally inelastic collision. I therefore choose the mosquito plus the bus as my system.

❷ **DEVISE PLAN** During the collision, the system is isolated, and so its momentum doesn't change. I can use this fact to compare the magnitudes of the changes in momentum. The average forces exerted on the mosquito and the bus are each equal to the corresponding momentum change divided by the time interval over which that momentum change takes place. I also know that this time interval is the same for the mosquito and the bus.

❸ **EXECUTE PLAN** (*a*) Because the system's momentum is unchanged, I know that $\Delta\vec{p}_{\text{mos}} = -\Delta\vec{p}_{\text{bus}}$ and so $|\Delta\vec{p}_{\text{mos}}| = |\Delta\vec{p}_{\text{bus}}|$. ✔

(*b*) Because the changes in momentum are equal in magnitude and because the time interval over which the change takes place is the same for both objects, the magnitudes of the average forces must also be equal: $|\vec{F}_{\text{by mos on bus, av}}| = |\vec{F}_{\text{by bus on mos, av}}|$. ✔

❹ **EVALUATE RESULT** Although the answer to part *a* conforms to what I've seen before, the answer to part *b* is surprising. Intuitively I expect the magnitude of the average force exerted by the bus to be much larger than the magnitude of the average force exerted by the mosquito because the mosquito is crushed while nothing happens to the bus. However, I know that the force magnitude required to crush the mosquito is very small, and such a small force magnitude would have no effect on the bus. It therefore makes sense that the two forces are of equal magnitude.

CONCEPTS

8.6 In Example 8.1, the mosquito has an inertia of 0.1 g and is initially at rest, while the bus, with an inertia of 10,000 kg, has an initial speed of 25 m/s. The collision lasts 5 ms. (*a*) Calculate the final speeds of the mosquito and the bus. (*b*) What is the average acceleration of each during the collision? (*c*) By how much does the momentum of each change? (*d*) During the collision, how large is the average force exerted by the bus on the mosquito? (*e*) How large is the average force exerted by the mosquito on the bus?

8.3 Identifying forces

To identify the forces exerted on an object, it is convenient to distinguish between contact forces and field forces:

- **Contact forces** are forces that arise when objects physically touch each other. This category of forces includes forces due to pushing, pulling, and rubbing.
- **Field forces** are forces associated with what is called "action at a distance." In this case, the objects exerting forces on each other do not need to be physically touching. For any object larger than atoms, gravitational and electromagnetic forces are the only field forces.

Identifying contact forces is easy: Whenever the surfaces of two objects touch, the objects exert contact forces on each other. Nearly all familiar forces fall into this category: the pull of a rope, the traction of a tire on a road, the force that keeps an airplane in the air, the push of a bumper, the hit of a hammer, the force that keeps you afloat when you are swimming, the drag caused by air resistance, and so on.

To determine which field forces to include in a given situation, gravitational and electromagnetic interactions must be considered. Gravitational interactions take place between any two objects. In our daily life, for instance, we each interact with Earth via the gravitational force, as does any other object—this book,* an apple, a house, and so on. The gravitational interaction we have with one another and with all other objects except Earth, however, is negligibly small. If you hold this book with your arms stretched out in front of you and let it go, it accelerates toward Earth, not toward you.

Because ordinary objects tend to be both electrically neutral and nonmagnetic, we usually do not need to

*Hold a book with your arms stretched out in front of you and move it up and down. Do you feel the gravitational force exerted by Earth on the book? You can visualize this interaction as an invisible stretched spring reaching from the center of Earth to the book. Imagine stretching and relaxing this "gravitational spring" as you move the book up and down.

consider field forces due to magnetic and electric interactions, unless a problem specifically mentions these types of interactions. We will treat electric and magnetic forces in detail in later chapters.

So, in most cases the only field force we need to consider is the gravitational force exerted by Earth. Only if a problem specifically mentions magnetic or electric interactions must we also take the field forces due to these interactions into account.

EXERCISE 8.2 What forces?

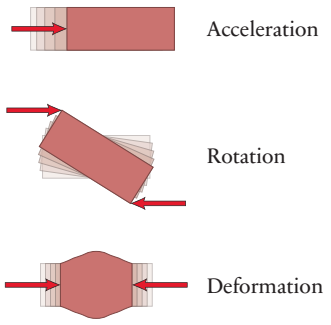
Identify all the forces exerted on the italicized object in each situation: (*a*) A *book* is lying on top of a magazine on a table. (*b*) A *ball* moves along a trajectory through the air. (*c*) A person is sitting on a *chair* on the floor of a room. (*d*) A *magnet* floats above another magnet that is lying on a table.

SOLUTION Because the interaction with the air is usually very small, I'm ignoring this interaction in this problem.

(*a*) Contact forces: The book is in contact with the magazine only, and so the magazine exerts a contact force on the book. Field forces: Earth exerts a gravitational force on the book. ✔

(*b*) Contact forces: The ball is not in contact with anything during its flight, and so there are no contact forces. Field forces: There is a gravitational interaction between Earth and the ball, so Earth exerts a gravitational force on the ball. ✔

(*c*) Contact forces: The chair is in contact with the floor and the person, and so both the floor and the person exert a force on the chair. Field forces: Earth exerts a gravitational force on the chair. ✔



(*d*) Contact forces: The magnet floats, so it is not in contact with anything and thus there are no contact forces. Field forces: Both gravitational and magnetic forces occur in this problem: a gravitational force exerted by Earth on the magnet and a magnetic force exerted by the second magnet. ✔

8.7 A magnet lies on a table. You place a second magnet near the first one so that the two repel each other. Identify all the forces exerted on the first magnet.

8.4 Translational equilibrium

An object or system whose motion or state is not changing is said to be in **equilibrium.** For example, an object at rest or moving at constant velocity—in other words, its momentum is constant and its acceleration is zero—is said to be in **translational equilibrium.** According to the definition of force given in Section 8.1, constant momentum implies that the vector sum of the forces exerted on the object must be zero. Note that being in translational equilibrium doesn't necessarily mean that no forces are exerted on the object. It means only that all the force vectors add up to zero and therefore do not change the object's momentum.

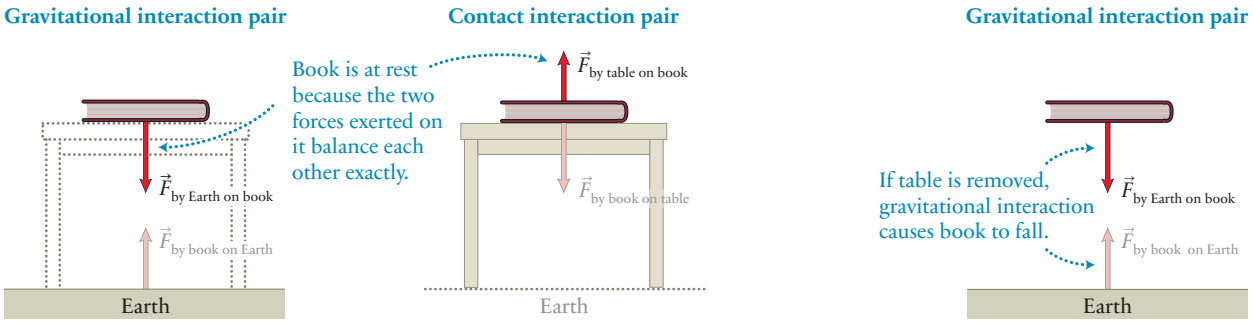
Figure 8.3 Forces can have various effects on an object.

As **Figure 8.3** illustrates, however, forces can also cause an object to rotate or to deform. Which combination of these effects occurs depends on where and how forces are exerted on the object. For now we consider only the acceleration caused by forces. Deformation is discussed in Chapters 7 and 8 and rotation in Chapter 11.

A book at rest on the floor is in translational equilibrium. So, too, is the crate pushed at constant velocity in Figure 8.1. In both of these cases, as with a coil spring squeezed between your hands, forces are exerted even though the object is in translational equilibrium.

Whenever an object is at rest or moving at constant velocity, the vector sum of the forces exerted on the object is zero, and the object is said to be in translational equilibrium.

As an example of an object in translational equilibrium, consider a book lying on a table, as in **Figure 8.4*a***. The book's momentum isn't changing, and therefore the vector sum of the forces exerted on it must be zero. What forces are exerted on the book? The only field force we need to consider is gravity. Even though the book is at rest, we know it is subject to gravity because if we suddenly remove the table from under it, the book accelerates downward (Figure 8.4*b*). Because the book is touching the table, we know there is a contact force exerted by the table on the book—the force that holds the book up and prevents it from falling through the table.



These are the only two forces exerted on the book. Because the vector sum of these forces must be zero, we conclude that the contact force exerted by the table on the book must be of the same magnitude as the gravitational force exerted by Earth on the book but in the opposite direction.

An object is also in translational equilibrium when it is moving at constant velocity. An example is the crate of Figure 8.1. Constant velocity means no change in momentum, and therefore the vector sum of the forces exerted on the crate must be zero. Considering only forces in the direction of motion, we determine two contact forces exerted on the crate: one by you pushing and one by the floor rubbing. In order for the

Figure 8.4

(*a*) Book at rest on table (vector sum of forces exerted on book is zero)

(*b*) Book in free fall (vector sum of forces exerted on book is not zero)

vector sum of these forces to be zero, the frictional force exerted by the floor on the crate must be of the same magnitude as the force exerted by you on the crate but in the opposite direction.

8.8 In Figure 8.4, are the contact force exerted by the table on the book and the gravitational force exerted by Earth on the book an interaction pair?

8.5 Free-body diagrams

Knowing about forces gives you a powerful tool for analyzing physical situations:

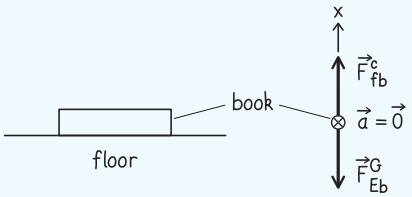
> **If the vector sum of the forces exerted on an object is known, the time rate of change in the object's momentum is also known, and so the object's subsequent motion can be calculated.**

Note the condition: To calculate the object's motion you need to know the vector sum of the forces exerted **on** the object only. The forces exerted **by** the object on its surroundings do not enter into the picture because they do not contribute to the change in the object's momentum. So, if you are considering an accelerating car and you need to calculate the time rate of change of its momentum, then you need to determine the vector sum of the forces exerted *on* the car (by the road, by the air, by gravity, and so on). The forces exerted *by* the car (on the road, on the air, . . .) determine what happens to those objects and not what happens to the car.

Whenever you are interested in one object in a collection of interacting objects, you must separate that one object and the forces exerted on it from the rest of the collection of objects and ignore the forces exerted by that object on anything else. To facilitate this separation, you should use what is called a **free-body diagram.** The procedure for drawing such diagrams is explained in "Drawing free-body diagrams." It is often also helpful to make a small sketch to identify the objects of interest. Be sure, however, to keep this "situation sketch" and your free-body diagram separate.

Until we begin to treat motion in more than one dimension in Chapter 10, we shall consider only the forces that are exerted in the direction of motion. For example, when pushing a cart on a horizontal track, you need only draw the forces along the horizontal direction. The forces along the vertical direction—an upward contact force exerted by the track on the cart and a downward gravitational force exerted by Earth on the cart—add up to zero and cause no change in the cart's motion.

The importance of free-body diagrams can hardly be exaggerated: Without a good free-body diagram, it is very difficult to analyze correctly any problem involving forces. In Section 4.4, I pointed out that separating a system from its environment is the most fundamental step in analyzing physical problems. Free-body diagrams help make this separation explicit. Let's therefore put the procedure into practice in a few examples.



CONCEPTS

EXERCISE 8.3 A book on the floor

Draw a free-body diagram for a book lying motionless on the floor.

SOLUTION I begin by drawing a small sketch of the situation. Next to it I draw a circle with a cross to represent the center of mass of the book—no line to represent the floor, just the center-of-mass symbol representing the book as if it were by itself in space (**Figure 8.5**). Of the objects in the book's environment, the only one I need to consider is the floor because that is the only thing in contact with the book.

Figure 8.5

PROCEDURE: Drawing free-body diagrams

1. Draw a center-of-mass symbol (a circle with a cross) to indicate the object you wish to consider*—this object is your system. Pretend the object is by itself in empty space (hence the name *free body*). If you need to consider more than one object in order to solve a problem, draw a separate free-body diagram for each.
2. List all the items in the object's environment that are in contact with the object. These are the items that exert *contact forces* on the object. *Do not add these items to your drawing*! If you do, you run the risk of confusing the forces exerted *on* the object with those exerted *by* the object.
3. Identify all the forces exerted *on* the object by objects in its environment. (For now, omit from consideration any force not exerted along the object's line of motion.) In general, you should consider (*a*) the *gravitational field force* exerted by Earth on the object and (*b*) the *contact force* exerted by each item listed in step 2.
4. Draw an arrow to represent each force identified in step 3. Point the arrow in the direction in which the force is exerted and place the tail at the center of mass. If possible, draw the lengths of the arrows so that they reflect the relative magnitudes of the forces. Finally, label each arrow in the form

$$\vec{F}^{\text{type}}_{\text{by on}},$$

where "type" is a single letter identifying the origin of the force (c for contact force, *G* for gravitational force), "by" is a single letter identifying the object exerting the force, and "on" is a single letter identifying the object subjected to that force (this object is the one represented by the center of mass you drew in step 1).
5. Verify that all forces you have drawn are exerted **on** and not **by** the object under consideration. Because the first letter of the subscript on $\vec{F}$ represents the object exerting the force and the second letter represents the object on which the force is exerted, every force label in your free-body diagram should have the same second letter in its subscript.
6. Draw a vector representing the object's acceleration *next to* the center of mass that represents the object. Check that the vector sum of your force vectors points in the direction of the acceleration. If you cannot make your forces add up to give you an acceleration in the correct direction, verify that you drew the correct forces in step 4. If the object is not accelerating (that is, if it is in translational equilibrium), write $\vec{a} = \vec{0}$ and make sure your force arrows add up to zero. If you do not know the direction of acceleration, choose a tentative direction for the acceleration.
7. Draw a reference axis. If the object is accelerating, it is often convenient to point the positive x axis in the direction of the object's acceleration.

When your diagram is complete it should contain only the center-of-mass symbol, the forces exerted *on* the object (with their tails at the center of mass), an axis, and an indication of the acceleration of the object. Do not add anything else to your diagram.

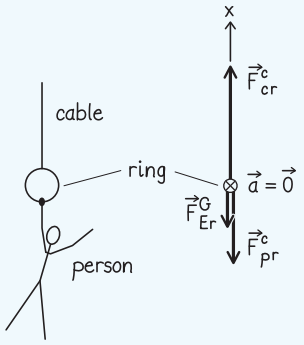
*Representing, say, a car by a single point might seem like an oversimplification, but because we are interested only in the motion of the car as a whole, any details (like its shape or orientation) do not matter. Any unnecessary details you add to your drawing only distract from the issue at hand.

CONCEPTS

Next I name the forces exerted on the book. First there is a downward gravitational force exerted by Earth on the book. In addition, there is the one contact force exerted by the floor on the book. This force, which prevents the book from falling down through the floor, is directed upward.

Then I add arrows to the sketch to represent the forces I have identified. To represent the gravitational force, I draw an arrow pointing vertically downward with its tail at the center of mass. I label this force with a superscript *G* (for *gravity*) and the subscript Eb to indicate that it is a force exerted *by* Earth (E) *on* the book (b). For the contact force, I draw an upward-pointing arrow with its tail at the center of mass. I label this force with a superscript c (for *contact*) and the subscript fb to indicate that it is a force exerted *by* the floor (f) *on* the book (b). Finally, I verify that all forces in the diagram have subscripts ending in b because my diagram should contain only forces exerted *on* the book.

Because the book is at rest, its acceleration is zero, and therefore I write $\vec{a} = \vec{0}$ near the center of mass. From this information, I conclude that the vector sum of the forces exerted on the book (the sum of the two force vectors I have drawn) must be zero. I therefore adjust the lengths of the two arrows in the diagram so that they are of equal length, as shown in Figure 8.5. I complete the diagram by drawing an upward-pointing x axis. ✔



8.9 If Exercise 8.3 had asked about a book in free fall rather than one on the floor, what would the free-body diagram look like?

EXERCISE 8.4 Hanging around

Consider a person hanging motionless from a ring suspended from a cable, with the person's feet not touching the floor. Draw a free-body diagram for the ring.

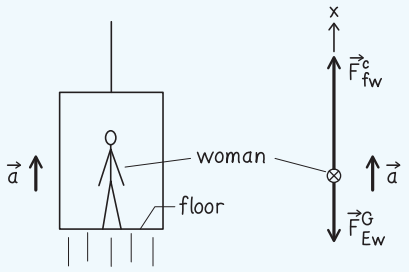
SOLUTION I begin by drawing a sketch of the situation and then a center-of-mass symbol representing the ring (**Figure 8.6**). The things in the environment in contact with the ring are the cable and the person.

Figure 8.6

The next step is to identify all the forces exerted on the ring. As in the preceding example—and in *all* other examples concerning situations at or near Earth's surface—a vertically downward gravitational force is exerted by Earth (E) on the ring (r). I therefore draw an arrow from the center of mass down and label it $\vec{F}^{G}_{Er}$.

Next there are the contact forces: contact with the cable (c) and contact with the person (p). I represent the latter with a second arrow pointing downward. Because I don't know how this force compares in magnitude with the force of gravity, I choose its length arbitrarily. The other contact force is exerted by the cable on the ring. Because this force holds the ring up, I add an arrow pointing upward. Finally, I verify that the subscripts for each force end in r for ring because my diagram should contain only forces exerted *on* the ring.

Because the ring remains at rest, its acceleration is zero, and so I write $\vec{a} = \vec{0}$ near the center of mass. This tells me that the upward and downward forces exerted on the ring must add up to zero. I therefore adjust the length of the upward arrow so that it is equal to the sum of the lengths of the two downward arrows. I complete the diagram by adding an upward-pointing x axis. ✔



8.10 Draw a free-body diagram for the person in Exercise 8.4.

EXERCISE 8.5 Elevator woman

A woman stands in an elevator that is accelerating upward. Draw a free-body diagram for her.

SOLUTION After making a situation sketch, I draw a center-of-mass symbol to represent the woman (**Figure 8.7**). The only thing she is in contact with is the elevator floor—it is the floor that pushes her upward.

Figure 8.7

The forces exerted on the woman are a downward gravitational force exerted by Earth and an upward contact force exerted by the floor. I add arrows to the diagram to represent these forces, label them as shown in Figure 8.7, and verify that they all have subscripts ending in w for woman.*

What is the woman's acceleration? Even though she is at rest in the elevator, her acceleration is not zero because the elevator and she are both accelerating upward. I indicate this acceleration with an arrow pointing upward.

The upward acceleration means that the vector sum of the forces exerted on the woman is nonzero and directed upward. This can happen only if the upward force exerted by the elevator floor is larger than the gravitational force exerted by Earth. Therefore I adjust the lengths of the arrows as shown in Figure 8.7. Because the elevator has an upward acceleration, I add an upward-pointing x axis to my drawing. ✔

Warning: When drawing a free-body diagram, you may be tempted to add an arrow to show the vector sum of the forces (the "net force"), but this is not good practice. First, by drawing a vector showing the acceleration of the object, you have already indicated the direction of the vector sum of the forces. Second, this vector sum is the result of all the forces you have already drawn, not a separate force exerted by something on the object in your free-body diagram.

8.11 You throw a ball straight up. Draw a free-body diagram for the ball (*a*) while it is still touching your hand and is accelerating upward, (*b*) at its highest point, and (*c*) on the way back down.

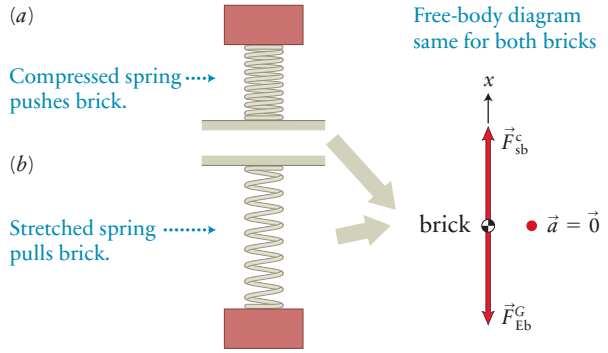
*If all the subscripts in a free-body diagram do not end in the same letter, do not merely change the subscripts! Repeat the identification of the forces and ask yourself if each force you drew points in the correct direction. For example, does the floor push up on the woman? Or did you draw the force that her feet exert *on the elevator floor*? Correct your diagram if necessary.

CONCEPTS

8.6 Springs and tension

To better understand the origin of contact forces like the upward push of a floor or the pull of a rope, let us examine the behavior of a spring. When a spring is neither stretched nor compressed, we say it is at its *relaxed length*. If you position a spring vertically and put a brick on top of it, as shown in **Figure 8.8*a***, the brick *compresses* the spring and comes to rest in a position below the relaxed length of the spring. Figure 8.8 also shows the free-body diagram for the brick, which is subject to a downward force of gravity and an upward contact force—a *push*—exerted by the spring. Because the brick is at rest, the vector sum of the forces exerted on it must be zero. So the push by the spring and the gravitational force exerted by Earth are equal in magnitude and point in opposite directions. In general, whenever a spring holds an object in place, the spring must exert on the object an upward force, called a *support force*, that is equal in magnitude to the downward gravitational force exerted by Earth on the object.

Similarly, if we suspend the spring from a ceiling and fasten the brick at the bottom, the spring stretches, exerting on the brick an upward force—a *pull*—that counteracts the downward force of gravity (Figure 8.8*b*). The free-body diagram for this situation is identical to the one for the compressed spring; in both cases there is an upward force exerted by the spring on the brick. For the purpose of drawing a free-body diagram, it makes no difference at all whether it is a push or a pull that keeps the brick in place.



The force exerted by the spring always tends to return the spring to its relaxed length. When the spring is stretched, it exerts a pull (back toward the spring); when it is compressed, it exerts a push (away from the spring). Forces exerted by springs are therefore called *restoring forces*.

Now imagine adding additional identical bricks on top of the one shown in Figure 8.8*a*. Each additional brick increases the force exerted on the spring and further compresses it. If we repeat this experiment with the spring suspended from a ceiling, the spring stretches increasingly as the force exerted on the spring increases.

Over a certain range, called the *elastic range*, the compression or stretching of the spring is reversible; that is, when the force causing the compression or stretching is removed, the spring returns to its original shape.* If stretched beyond a certain point, called the *elastic limit*, the spring no longer reverts to its original length when the load (the brick) is removed. Additional load stretches the spring further until it eventually reaches the breaking point.

*As you might have noticed, the word *elastic* is associated with reversible phenomena: Elastic collisions are reversible, elastic potential energy is associated with reversible deformations, and so on.

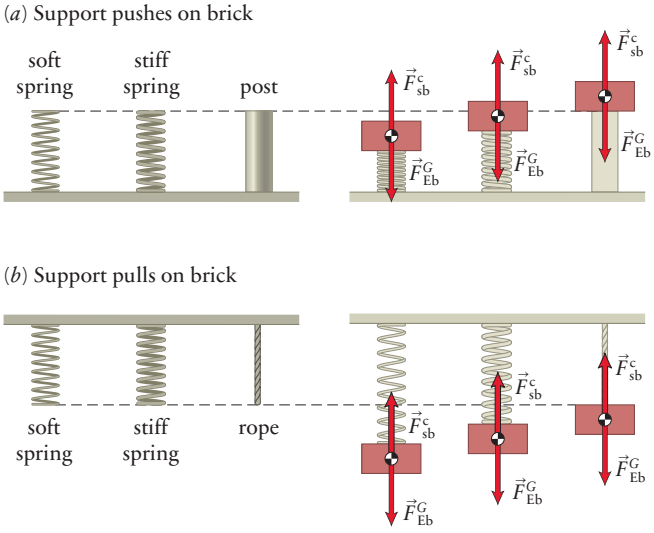


Figure 8.8 The free-body diagram for the brick is the same whether the spring (*a*) pushes or (*b*) pulls on it.

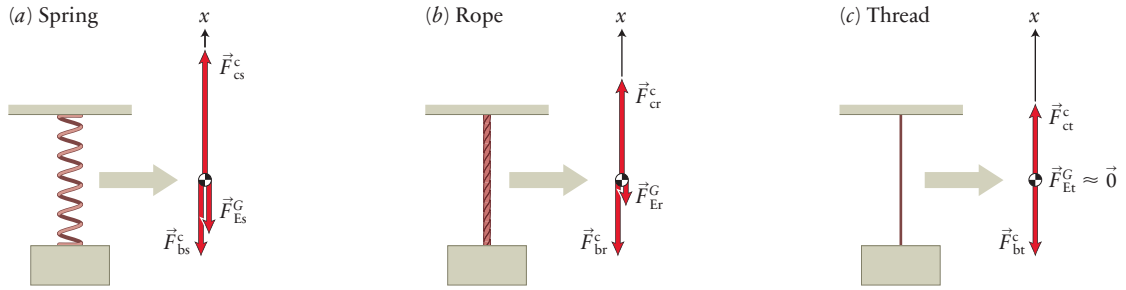
The amount of compression or stretching of a spring depends not only on the force exerted on the spring but also on the *stiffness* of the spring. A soft spring compresses or stretches more than a stiffer spring does under the same load (that is, when the same force is exerted on it). As **Figure 8.9** shows, however, the soft and stiff springs *exert exactly the same support force on the load*.



Now imagine putting a brick on a very stiff spring—one meant to support, say, a truck. You are unlikely to be able to see the spring compress (although you can measure the compression), but as with any other spring, compression is necessary in order to generate the upward force that holds the brick in place. With a very stiff spring, you need only a tiny compression to generate this support force. Even a solid object compresses a tiny bit when it supports another object, and as with a spring, the more load you pile on top of a solid object, the more it compresses in order to generate the force necessary to support its load.

Figure 8.9 A soft spring exerts the same force on a given load as a stiff spring or a post or a rope, even though it deforms much more. In fact, the post and rope behave like very stiff springs, compressing and stretching very slightly in response to the load.

CONCEPTS

Figure 8.10 Free-body diagrams for a spring, rope, and thread that suspend a brick from the ceiling.

Everything around you behaves this way: the chair you sit on, the bed you lie on, the floor you walk on, the road you drive on, and so on. Like a soft spring, an upholstered chair compresses noticeably when you sit on it. Sit on a table, though, and it "gives" a lot less. Even a concrete floor or a steel chair must compress ever so slightly to support you. The upholstered chair, the table, the concrete floor, and the steel chair all exert on you a support force that is equal in magnitude to the force of gravity exerted on you.

The same arguments can be applied to stretched objects (Figure 8.9*b*). In particular, the pull of a rope is like the pull of a stretched spring because the rope, like a very stiff spring, stretches ever so slightly while providing the support force that holds the object in place. As long as the deformation is reversible, the force exerted by a compressed or stretched material is called an **elastic force.**

Let us now turn our attention to the forces exerted *on* the object being compressed or stretched. **Figure 8.10*a*** shows a free-body diagram for a spring suspended from a ceiling and stretched by a brick. In addition to the two contact forces exerted by the ceiling and the brick on the spring, the spring is subject to a downward gravitational force. Because the spring is at rest, the upward force must be equal in magnitude to the sum of the downward forces exerted by gravity and the brick.

CONCEPTS

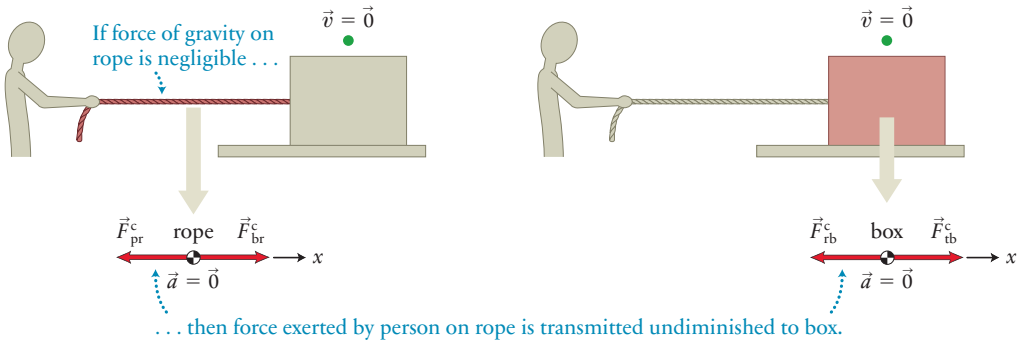
8.12 In Figure 8.10*a*, how does the magnitude of the downward force exerted *by the spring on the ceiling* compare with the magnitudes of the downward gravitational forces exerted by Earth on the spring and on the brick?

Check your answer to Checkpoint 8.12 before proceeding!

Figures 8.10*b* and 8.10*c* show free-body diagrams for a rope and a thread stretched by the same brick as in Figure 8.10*a*. The lower the inertia of the object being stretched, the smaller the force of gravity exerted on it. For objects of very low inertia, the magnitude of the gravitational force approaches zero, and the magnitudes of the two contact forces (exerted by the ceiling and the brick) become equal, as Figure 8.10*c* shows.

Because of the reciprocity of forces, the force exerted *by the thread on the ceiling* (not shown in the diagram) is equal in magnitude to the force exerted by the brick on the thread. Because these two forces point in the same direction, the thread simply transmits the pulling force of the brick to the ceiling.

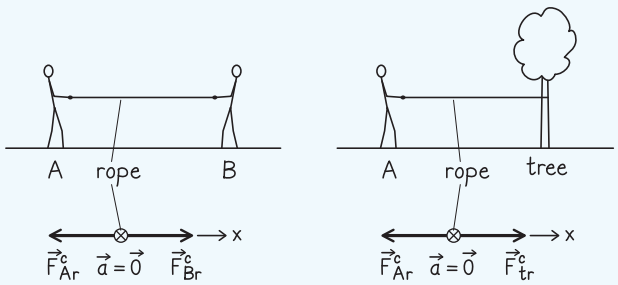
Of course, we don't usually use thread to pull on objects, but in situations in which a rope—or even a lightweight chain—is used to pull, we can generally ignore the gravitational force exerted on the rope or chain. The only requirement is that the pulling force be much greater than the gravitational force exerted on the rope or chain. So, if we ignore the gravitational force, the same transmission of forces described for our thread is seen when we use a rope. If you fasten a rope to a boat and pull on one end of the rope, the rope stretches a little and the opposite end of the rope transmits your force to the boat. In general, if the force of gravity exerted on any object being stretched—rope, spring, thread—is much smaller than the forces that cause the stretching (and acceleration is zero), you can ignore the force of gravity. This is usually true when ropes, springs, or threads are used to pull or push on objects. Therefore:



> **The force exerted on one end of a rope, spring, or thread is transmitted undiminished to the other end, provided the force of gravity on the rope, spring, or thread is much smaller than the forces that cause the stretching.**

A rope being used to pull an object is subject to two equal outward forces, one on each end (**Figure 8.11**). The stress caused by this pair of forces is called the **tension** in the rope, and the forces causing the tension are called *tensile forces*. Tension is a scalar and is represented by $\mathcal{T}$. In an object subject to two equal tensile forces of magnitude F, one on each end of the object, the tension is $\mathcal{T} = F$.

EXAMPLE 8.6 Tug of war



If two people, A and B, pull on opposite ends of a rope that is at rest, each exerting a horizontal tensile force of magnitude F, the tension in the rope is $\mathcal{T} = F$. Suppose instead that one end of the rope is tied to a tree and A pulls on the other end by himself with the same force magnitude F. Is the tension in the rope larger than, equal to, or smaller than the tension when A and B pull on opposite ends?

Figure 8.11 Transmission of a force by a rope to a box. Free-body diagrams for (*a*) the rope and (*b*) the box. (We assume that the force of gravity on the rope is much smaller than the forces exerted by the person and the box, so we can ignore it.)

1 GETTING STARTED To determine the tension in each case, I need to know the magnitude of the tensile force exerted on each end of the rope. I begin by making a sketch of the two situations (**Figure 8.12**).

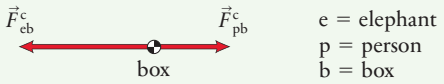
Figure 8.12

2 DEVISE PLAN Because I must analyze various forces exerted on the rope, it is best to begin with a free-body diagram for the rope. In a tug of war only the horizontal forces matter, so I ignore the effect of the vertical gravitational force exerted by Earth and consider only the horizontal forces (Figure 8.12). Because the rope is always at rest, I know that the vector sum of the forces exerted on the rope must be zero. The magnitudes of the tensile forces exerted on either end are therefore equal to each other, and the tension in the rope is equal to the magnitude of the tensile force exerted on either end.

3 EXECUTE PLAN The rope tied to the tree is subject to two contact forces, one exerted by A and the other exerted by the tree. Because the vector sum of the forces exerted on the rope must be zero, I make the two force arrows of equal length, as shown in my free-body diagram.

Because A pulls on the rope with a force of magnitude F, the tree must pull with a force of magnitude F in the opposite direction, and so the tension in the rope is $\mathcal{T} = F$, which is the same as when A and B pull on opposite ends. ✔

4 EVALUATE RESULT The magnitude of the force exerted by A is F in both cases. Because the rope has zero acceleration in both cases, the magnitude of the force exerted by the tree must be the same as the magnitude of the force exerted by B when A and B pull. Therefore it makes sense that the tension in the rope is the same in the two cases.



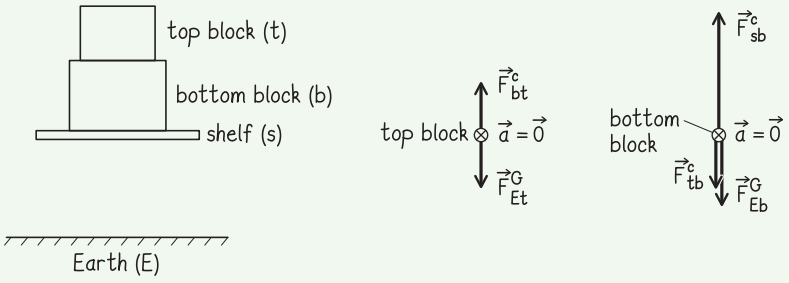
8.13 In Example 8.6, suppose both people pull on the same end of the rope, each exerting a force F, while the other end is still tied to the tree. Is the tension in the rope larger than, equal to, or smaller than the tension when the two people pull on opposite ends?

CONCEPTS

Self-quiz

1. (*a*) Two forces, one twice the magnitude of the other, are exerted on identical objects during the same time interval. Which force causes the greater change in momentum? (Assume that no other forces act on the objects.) (*b*) Two identical forces are exerted on identical objects, one during a time interval twice as long as the other. Which force causes the greater change in momentum? (Assume that no other forces act on the objects.)
2. The free-body diagram of a box subjected to forces is shown in Figure 8.13. Because we are concerned about only the horizontal motion, the forces in the vertical direction have been omitted. (*a*) What is the direction of the change in the momentum of the box? (*b*) If the box is at rest before the forces shown in the diagram are exerted on it, what is the direction of its momentum once the forces are exerted?

Figure 8.13



3. For the free-body diagram in question 2, list the objects in the environment of the box.
4. A block of wood rests on a shelf, and a second block of wood rests on top of the first. (*a*) List the objects in the environment of the top block. (*b*) List the objects in the environment of the bottom block. (*c*) Draw a free-body diagram for each block.
5. Complete the following sentences, applying the reciprocity of forces. (Example: If I push down on the seat of my chair, *the seat of my chair pushes up on me*.)

   If I push to the right on the wall, . . .
   If I pull to the right on a spring, . . .
   If the floor pushes up on my feet, . . .
   If Earth pulls down on me, . . .

Answers

1. (*a*) The larger force causes the greater change in momentum because force and change in momentum are proportional to each other over a given time interval. (*b*) The force exerted over the longer time interval causes the greater change in momentum because time interval and change in momentum are proportional to each other for a constant force.
2. (*a*) The vector sum of the forces exerted on the box points to the left because the force exerted on the box by the elephant is larger than the force exerted on the box by the person. The change in momentum is to the left, in the same direction as the vector sum of the forces. (*b*) The change in momentum is equal to the final momentum minus the initial momentum of zero. Therefore, the final momentum of the box must be to the left.
3. The objects in the environment of the box are an elephant and a person. If you also consider the vertical direction, you need to include the ground and Earth as being in the environment of the box.
4. (*a*) The objects in the environment of the top block are the bottom block and Earth. The shelf is not in contact with the top block and so is not part of the top block's environment. (*b*) The objects in the environment of the bottom block are the shelf, the top block, and Earth. (*c*) See Figure 8.14. Earth pulls downward on each block. The surface below each block pushes upward. If the bottom block pushes upward on the top block, the top block must push down on the bottom block.

Figure 8.14

5. For each, swap the nouns and reverse the given direction.

   If I push to the right on the wall, *the wall pushes to the left on me.*
   If I pull to the right on a spring, *the spring pulls to the left on me.*
   If the floor pushes up on my feet, *my feet push down on the floor.*
   If Earth pulls down on me, *I pull up on Earth.**

*Many people find this last statement difficult to accept and are inclined to answer: If Earth pulls down on me, the ground pushes up on me. That answer, however, includes three objects (ground, Earth, me), not just the two required by the reciprocity of forces.

8.7 Equation of motion

In the first part of this chapter, we determined that the vector sum of the forces exerted on an object is equal to the time rate of change in the object's momentum. If an object's momentum changes by an amount $\Delta\vec{p}_{\text{object}}$ in a time interval Δt, the *average* time rate of change in the object's momentum is

$$\frac{\Delta\vec{p}_{\text{object}}}{\Delta t}. \tag{8.1}$$

The *instantaneous* time rate of change in momentum is obtained by letting the time interval approach zero:

$$\lim_{\Delta t\to 0}\frac{\Delta\vec{p}_{\text{object}}}{\Delta t} = \frac{d\vec{p}_{\text{object}}}{dt} \equiv \Sigma\vec{F}_{\text{object}}, \tag{8.2}$$

where $\Sigma\vec{F}_{\text{object}}$ represents the vector sum of all the forces exerted on the object:*

$$\Sigma\vec{F}_{\text{object}} = \vec{F}_{1\text{ object}} + \vec{F}_{2\text{ object}} + \vec{F}_{3\text{ object}} + \cdots, \tag{8.3}$$

where $\vec{F}_{1\text{ object}}$ is the force exerted by object 1 on the object under consideration, and so on. Because we are concerned with only one object, we can omit the subscript on the left side of Eq. 8.3, and so Eq. 8.2 becomes

$$\Sigma\vec{F} \equiv \frac{d\vec{p}}{dt}. \tag{8.4}$$

The vector sum of the forces points in the same direction as the change in momentum of the object.

Substituting $\vec{p} \equiv m\vec{v}$ in the term on the right in Eq. 8.4 gives

$$\frac{d\vec{p}}{dt} \equiv \frac{d(m\vec{v})}{dt} = m\frac{d\vec{v}}{dt}, \tag{8.5}$$

where I have used the fact that the inertia m of the object is constant. Because $d\vec{v}/dt$ is the acceleration $\vec{a}$ of the object, substituting Eq. 8.5 into Eq. 8.4 yields

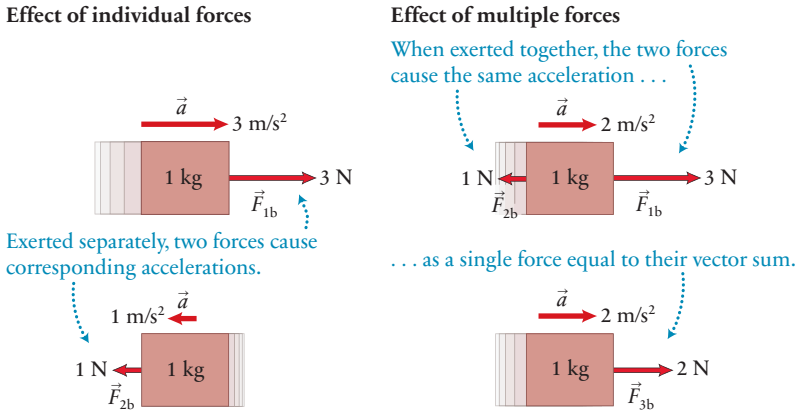
$$\Sigma\vec{F} = m\vec{a} \tag{8.6}$$

or

$$\vec{a} = \frac{\Sigma\vec{F}}{m}. \tag{8.7}$$

In terms of components, Eqs. 8.6 and 8.7 become

$$\Sigma F_x = ma_x \quad \text{and} \quad a_x = \frac{\Sigma F_x}{m}. \tag{8.8}$$



Equation 8.7 is called the **equation of motion** for the object. For a given vector sum of forces, this equation allows us to obtain the acceleration and therefore to determine the motion of the object. Conversely, if we know the acceleration of an object, Eq. 8.6 allows us to determine the vector sum of the forces exerted on that object.

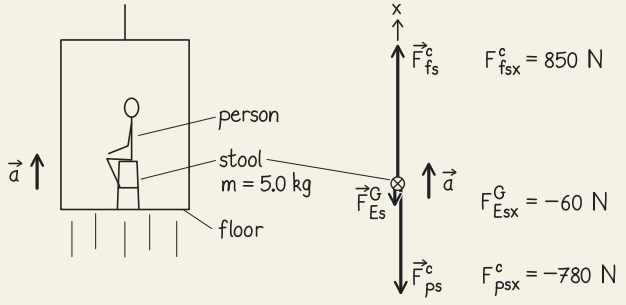
Because the SI unit of momentum is kg · m/s and the SI unit of time is seconds, the SI unit of force is kg · m/s^2. This derived SI unit is given the special name **newton** (N) in honor of the English scientist Isaac Newton:

$$1\text{ N} \equiv 1\text{ kg}\cdot\text{m/s}^2. \tag{8.9}$$

*We drop the "by" subscript because the sum represents the forces exerted by *all* objects on the object under consideration.

Figure 8.15 Superposition of forces.

This definition means that a force of 1 N exerted on an object that has an inertia of 1 kg causes that object to accelerate at 1 m/s^2.



Note that while several forces can be exerted simultaneously on a single object, that object can have only one acceleration. For example, if a 1-kg object is simultaneously subject to two forces—say, a 3-N force directed to the right and a 1-N force directed to the left—the object accelerates at 2 m/s^2 to the right, just as if a single force of 2 N directed to the right had been exerted (see **Figure 8.15**). The reason forces can be added vectorially is that the effect of a force is a change in momentum, and momentum is a vector quantity. This property of adding forces vectorially is called the *superposition of forces*.

EXAMPLE 8.7 Elevator stool

A person is sitting on a stool in an elevator. The forces exerted on the stool are a downward force of magnitude 60 N exerted by Earth, a downward force of magnitude 780 N exerted by the person, and an upward force of magnitude 850 N exerted by the elevator floor. If the inertia of the stool is 5.0 kg, what is the acceleration of the elevator?

1 GETTING STARTED I know all the forces that are exerted on the stool, and I must determine its acceleration. I therefore begin by drawing a free-body diagram for the stool that includes the three forces mentioned in the problem statement (**Figure 8.16**). I arbitrarily choose an x axis pointing upward.

Figure 8.16

2 DEVISE PLAN Equation 8.8 gives a relationship between the vector sum of the forces exerted on an object and the acceleration of the object. By substituting the forces given and the inertia of the stool, I can solve for a_x.

3 EXECUTE PLAN From Eq. 8.8, I have

$$a_x = \frac{\Sigma F_x}{m} = \frac{1}{m}(F^c_{fsx} + F^c_{psx} + F^G_{Esx})$$

$$= \frac{1}{5.0\ \text{kg}}[(+850\ \text{N}) + (-780\ \text{N}) + (-60\ \text{N})]$$

$$= +2.0\ \text{m/s}^2. \checkmark$$

4 EVALUATE RESULT The acceleration I obtained is positive, which means that the elevator has an upward acceleration, which is what I expect because the force exerted by the floor on the stool is upward. The magnitude of the acceleration is about one-fifth the acceleration due to gravity, which strikes me as a reasonable value.

8.14 (*a*) You exert a constant force of 200 N on a friend on roller skates. If she starts from rest, estimate how far she moves in 2.0 s. (*b*) When a person jumps off a wall, what is the magnitude of his acceleration? (*c*) Estimate the magnitude of the force exerted by Earth on the person during the jump in part *b*.

QUANTITATIVE TOOLS

As we saw in Section 8.2, forces always come in interaction pairs. To see this quantitatively, consider an isolated system of two colliding carts. As we have seen before, the momentum of the two-cart system is constant, and so the changes in momentum caused by the collision must obey the relationship

$$\Delta\vec{p}_1 + \Delta\vec{p}_2 = \vec{0}, \tag{8.10}$$

where $\Delta\vec{p}_1$ is the change in momentum of cart 1 and $\Delta\vec{p}_2$ is that of cart 2. During an infinitesimal time interval dt, this relationship yields

$$d\vec{p}_1 + d\vec{p}_2 = \vec{0}. \tag{8.11}$$

Because dt is the same for both carts, the time rates of change in momentum must also add to zero:

$$\frac{d\vec{p}_1}{dt} + \frac{d\vec{p}_2}{dt} = \vec{0}. \tag{8.12}$$

According to Eq. 8.4, the time rate of change of momentum of an object is equal to the vector sum of the forces exerted on that object, and so

$$\Sigma\vec{F}_1 + \Sigma\vec{F}_2 = \vec{0}. \tag{8.13}$$

Because the carts are constrained to move in the horizontal direction, the forces in the vertical direction cancel, and so the only forces exerted on the carts we need to consider are those they exert on each other. The vector sum of the forces exerted on cart 1 is thus just the force exerted by cart 2 on cart 1, and the vector sum of the forces exerted on cart 2 is just the force exerted by cart 1 on cart 2:

$$\Sigma\vec{F}_1 = \vec{F}_{21} \quad \text{and} \quad \Sigma\vec{F}_2 = \vec{F}_{12}, \tag{8.14}$$

and thus $\vec{F}_{12} + \vec{F}_{21} = \vec{0}$, or

$$\vec{F}_{12} = -\vec{F}_{21}. \tag{8.15}$$

Newton's laws of motion

In the modern view, the conservation laws are the heart and soul of physics—they best represent the generally held belief that the universe has an underlying simplicity. In the 17th century, however, 200 years before the concept of energy and the conservation laws were formulated, the English scientist Isaac Newton published a work describing his ideas concerning the fundamental principles that govern forces and their effects on the motion of objects. Newton's three laws of motion, as they are known, have been the backbone of physics for more than two centuries.

We have already discussed each of these three laws—albeit under different, and in the current context more appropriate, names.

Newton's first law of motion, first formulated by Galileo Galilei, is what we called the *law of inertia* in Chapter 6:

> **In an inertial reference frame, any isolated object that is at rest remains at rest, and any isolated object that is in motion keeps moving at a constant velocity.**

Newton's second law of motion corresponds to the *definition of force* given in Eq. 8.4:

> **The vector sum of the forces exerted on an object is equal to the time rate of change in the momentum of that object.**

Equation 8.6, $\Sigma\vec{F} = m\vec{a}$, is frequently referred to as Newton's second law even though it holds only when m is constant.

Newton's third law of motion expresses the law of conservation of momentum in terms of forces (Eq. 8.15):

> **Whenever two objects interact, they exert on each other forces that are equal in magnitude but opposite in direction.**

Newton is widely regarded as one of the greatest physicists of all time, not only for his formulation of the laws of motion but also for his law of gravity, for his development of the calculus, and for laying the foundation of modern optics.

In words, whenever two objects interact, they exert forces on each other that are equal in magnitude and opposite in direction. The forces $\vec{F}_{12}$ and $\vec{F}_{21}$ form an **interaction pair.** Because interactions always involve two objects, every force that is exerted *on* an object has associated with it a force of equal magnitude in the opposite direction exerted *by* the object. Note, in Eq. 8.15, that the subscripts on the forces that form an interaction pair are interchanged. For that reason, both forces in an interaction pair can never be part of the same free-body diagram. Equation 8.15 is called **Newton's third law of motion** (see the box "Newton's laws of motion" on page 261); it is a direct consequence of the conservation of momentum expressed in Eq. 8.10.

8.15 If forces always come in interaction pairs and the forces in such a pair are equal in magnitude and opposite in direction (Eq. 8.15), how can the vector sum of the forces exerted on an object ever be nonzero?

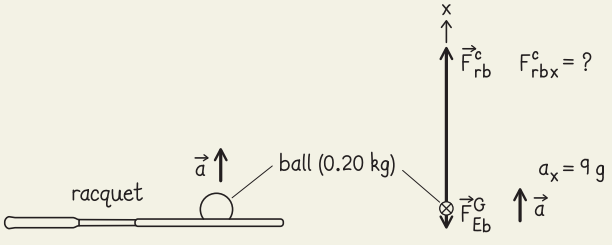
8.8 Force of gravity

We have seen before that, when we ignore air resistance, all objects dropped from a certain height near Earth's surface have a downward acceleration given by $a_x = -g$ when we define up as being the positive x direction (see Chapter 3). For an object in free fall near Earth's surface, the only force exerted on the object is the gravitational force $\vec{F}^G_{\text{Eo}}$ exerted by Earth on the object. The left side of Eq. 8.8 is thus

$$\Sigma F_x = F^G_{\text{Eo}x}. \tag{8.16}$$

The right side is $ma_x = -mg$, where m is the inertia of the object, and so the x component of the gravitational force exerted by Earth on the object is

$$F^G_{\text{Eo}x} = -mg \text{ (near Earth's surface, } +x \text{ axis vertically upward).} \tag{8.17}$$



The minus sign reflects the fact that the acceleration due to gravity (and therefore also the force of gravity) is directed downward and the positive x direction points upward. Because the acceleration due to gravity is the same for all objects, Eq. 8.17 holds for all objects in free fall near Earth's surface. Note that when additional forces are exerted on the object, the x component of the gravitational force exerted by Earth on the object is still given by Eq. 8.17, even though the x component of the object's acceleration is no longer equal to $-g$.

EXAMPLE 8.8 Tennis ball launch

A tennis ball of inertia 0.20 kg is launched straight up in the air by hitting it with a racquet. If the magnitude of the acceleration of the ball while it is in contact with the racquet is $9g$, what are the magnitude and direction of the force exerted by the racquet on the ball?

❶ GETTING STARTED I am given the inertia and acceleration magnitude for a tennis ball hit by a racquet, and I must calculate the force—both magnitude and direction—responsible for this acceleration. Because this problem deals with forces exerted on the ball, I begin by drawing a situation sketch and a free-body diagram for the ball (Figure 8.17). While it is being hit, the ball is in contact with the racquet and so I include an upward contact force exerted by the racquet as well as a downward force of gravity exerted by Earth. Because the ball accelerates upward, I make the upward force vector longer than the downward force vector and point the positive x axis upward.

Figure 8.17

❷ DEVISE PLAN Equation 8.8 relates the ball's acceleration to the vector sum of the two forces exerted on it. I can use Eq. 8.17 to calculate one of the two forces and then solve for the other one in Eq. 8.8.

QUANTITATIVE TOOLS

3 EXECUTE PLAN Equation 8.8 yields

$$\Sigma F_x = F^G_{\mathrm{Eb}x} + F^c_{\mathrm{rb}x} = ma_x.$$

Because I've defined upward as the positive x direction, $a_x = +9g$. Substituting this value and Eq. 8.17 for the gravitational force exerted by Earth on the object, I get

$$(-mg) + F^c_{\mathrm{rb}x} = +9mg$$

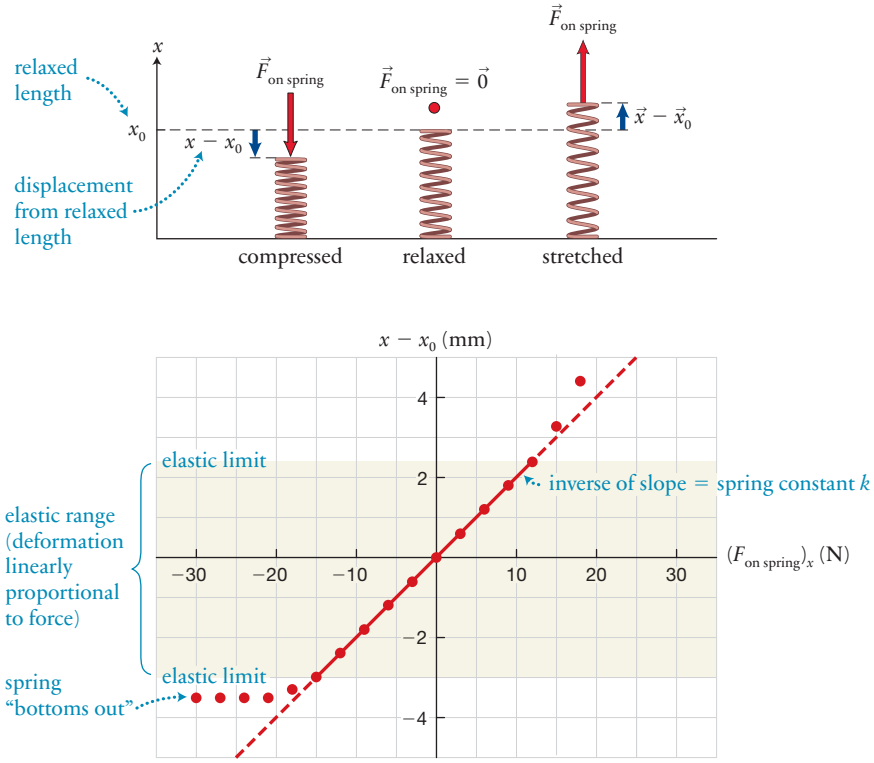
or
$$F^c_{\mathrm{rb}x} = +10mg = +10\,(0.20\ \mathrm{kg})\,(9.8\ \mathrm{m/s^2})$$
$$= +20\ \mathrm{N}. \checkmark$$

4 EVALUATE RESULT The plus sign indicates that this force is directed upward, as expected. The magnitude of the force is ten times larger than the gravitational force exerted by Earth, which also makes sense if the ball is to be accelerated upward during the very short time interval that the racquet is in contact with the ball.

8.16 The magnitude of the gravitational force exerted by Earth on an object of inertia m_1 is $m_1 g$. (*a*) What is the magnitude of the force exerted by the object on Earth (inertia m_E)? (*b*) What is the acceleration of Earth due to its gravitational interaction with the object?

Equation 8.17 shows that the magnitude of the force of gravity exerted on an object is proportional to the object's inertia, which is an intrinsic property of the object that has nothing to do with the presence of Earth or with gravity. This surprising conclusion is a direct consequence of the fact that, when air resistance is negligible, all objects experience the same acceleration due to gravity. It is more difficult to accelerate a large boulder than a feather, but the gravitational forces exerted by Earth on the boulder and on the feather are such that both have the same acceleration when they fall (ignoring air resistance). Equation 8.17 doesn't tell us much about the mechanism of gravity; it merely tells us what magnitude and direction the force of gravity must have to account properly for the free fall of objects near the surface of Earth. In Chapter 13, we'll return to the subject of gravity and its relationship to inertia. In the meantime, we can use Eq. 8.17 to calculate the magnitude of the force of gravity on any object near the surface of Earth.

8.17 Suppose you are in an elevator that is accelerating upward at 1 m/s^2. (*a*) Draw a free-body diagram for your body. (*b*) Determine the magnitude of the force exerted by the elevator floor on you.



8.9 Hooke's law

Now that we have established the relationship between the inertia of an object and the gravitational force exerted on it (Eq. 8.17), we can analyze the behavior of springs quantitatively. We begin by attaching bricks to the free end of a spring that is suspended from a ceiling. Each additional brick increases the force exerted on the spring and the amount by which the spring stretches. We repeat this experiment, but now we support the spring on a solid surface and stack bricks on top of it. Each additional brick increases the force exerted on the spring and further compresses it, up to the point where the spring "bottoms out"—which means its coils get in the way of further compression.

The graph in **Figure 8.18** on the next page shows the x component of the displacement of the free end of the spring from its relaxed position at x_0 versus the x component of the force exerted *on* the spring *by* the bricks. The shaded region indicates the elastic range. The first thing to note is that, within the elastic range, the displacement and the force exerted by the load on the spring are linearly proportional to each other. The second thing to note is that the force exerted on the spring is always in the same direction as the displacement. We can express this quantitatively as

$$(F_{\text{by load on spring}})_x = k(x - x_0) \quad \text{(small displacement)}, \qquad (8.18)$$

Figure 8.18 The x component of the displacement of the free end of the spring from its relaxed position is proportional to the x component of the force causing the displacement.

where k is called the **spring constant.** The spring constant represents the inverse of the slope of the straight line through the data points in Figure 8.18; it tells us how large a force is required to give the free end of the spring a displacement $x - x_0$. The spring constant is therefore a quantitative measure of the stiffness of the spring discussed in Section 8.6. It is always positive, but different springs have different values of k, depending on how they respond to compression and stretching. The SI unit of the spring constant is N/m.

Often we are interested not in the force exerted *on* the spring, but in the force exerted *by* the spring. We know from Eq. 8.15 that

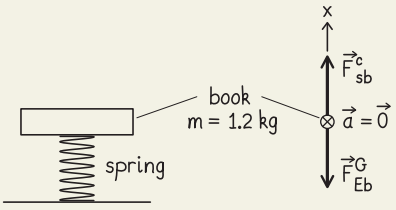
$$\vec{F}_{\text{by spring on load}} = -\vec{F}_{\text{by load on spring}} \tag{8.19}$$

and so the force exerted by the spring is given by

$$(F_{\text{by spring on load}})_x = -k(x - x_0) \quad \text{(small displacement)}. \tag{8.20}$$

Note that the direction of the force of the spring on the load is opposite to the direction of the displacement. A stretched spring pulls back. A compressed spring pushes out. Equation 8.18 (or its equivalent, Eq. 8.20) is called **Hooke's law** after the British physicist Robert Hooke (1635–1703), who first discovered the linear relationship between a spring's stretching or compression and the force exerted on it.

Unlike the conservation principles, which are of universal validity, Eq. 8.20 is valid for only small displacement. As Figure 8.18 shows, Hooke's "law" fails if we compress or stretch the spring beyond certain limits. Still, Hooke's law is of great use because, for small deformations, many materials—from steel to foam—show a linear relationship between force and displacement when compressed or stretched. For this reason, the force that tends to return a stretched or compressed spring or material to its relaxed position is referred to as a *linear restoring force*.



QUANTITATIVE TOOLS

EXAMPLE 8.9 Spring compression

A book of inertia 1.2 kg is placed on top of the spring in Figure 8.18. What is the displacement of the top end of the spring from the relaxed position when the book is at rest on top of the spring?

❶ **GETTING STARTED** My task is to determine how much the top end of a spring is displaced when a 1.2-kg book is placed on the spring. Hooke's law tells me that this displacement is proportional to the force exerted by the spring on the book, so after making a sketch of the situation, I draw a free-body diagram for the book. The book is subject to a downward gravitational force exerted by Earth and an upward contact force exerted by the spring (**Figure 8.19**). Because the book is in translational equilibrium, the book's acceleration is zero and so the two forces are equal in magnitude. I arbitrarily point the x axis upward.

Figure 8.19

❷ **DEVISE PLAN** I can use Eq. 8.20 to determine the displacement, but in order to do so I need to know the spring constant k and the x component F^{c}_{sbx} of the force exerted by the spring on the book. The spring constant is given by the slope of the curve in Figure 8.18. From my free-body diagram I know that $\vec{F}^{c}_{sb}$ is equal to the negative of the force of gravity $\vec{F}^{G}_{Eb}$ exerted by Earth on the book.

❸ **EXECUTE PLAN** From the graph in Figure 8.18, I arbitrarily choose 25 N as my force value and see that it causes a displacement of 5.0 mm. The spring constant is thus, from Eq. 8.18:

$$k = \frac{(F_{\text{by load on spring}})_x}{x - x_0} = \frac{+25\ \text{N}}{+5.0 \times 10^{-3}\ \text{m}} = 5.0 \times 10^{3}\ \text{N/m}.$$

Because the book is at rest, I know that $\vec{F}^{c}_{sb} + \vec{F}^{G}_{Eb} = \vec{0}$, and so $\vec{F}^{G}_{Eb} = -\vec{F}^{c}_{sb}$. The force of gravity is given by Eq. 8.17, and so I get for the force exerted by the spring on the book

$$\begin{aligned} F^{c}_{sbx} &= -F^{G}_{Ebx} \\ &= -(-mg) \\ &= (1.2\ \text{kg})(9.8\ \text{m/s}^2) \\ &= +12\ \text{N}. \end{aligned}$$

Substituting this value and the spring constant into Eq. 8.20, I obtain for the displacement:

$$\begin{aligned} x - x_0 &= \frac{-F^{c}_{sbx}}{k} \\ &= \frac{-12\ \text{N}}{5.0 \times 10^{3}\ \text{N/m}} \\ &= -2.4 \times 10^{-3}\ \text{m}. \checkmark \end{aligned}$$

❹ **EVALUATE RESULT** It makes sense that the force exerted by the book on the spring is equal to the force exerted by Earth on the book ($\vec{F}^{G}_{Eb} = \vec{F}^{c}_{bs}$) because the spring has to keep the book from being pulled downward into the ground. I can thus also obtain my answer by reading off the displacement from Figure 8.18 for a force of magnitude 12 N (the magnitude of the force of gravity exerted on the book). This procedure yields a value that is very close to the result I obtained. The negative sign in my answer indicates that the top end of the spring is displaced downward, as I expect.

8.18 (*a*) Is a spring that has a large spring constant k stiffer or softer than a spring that has a small spring constant? (*b*) Which has a larger spring constant: steel or foam rubber?

8.10 Impulse

Back in Chapter 4 we defined the change in momentum of a system or object as the impulse delivered to it. In this section we determine a relationship between force and impulse, which permits us to determine the effect forces have on momentum.

We begin by considering a simple case: a single object subject to constant forces. To calculate what happens to the momentum of the object, we consider its motion during a time interval $\Delta t = t_f - t_i$. The constant

forces exerted on the object give it a constant acceleration $\vec{a}$ given by Eq. 8.7. Because the acceleration is constant, we can write

$$\vec{a} = \frac{\Delta\vec{v}}{\Delta t}. \tag{8.21}$$

Multiplying both sides by the inertia m of the object, we get

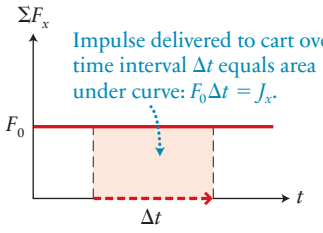
$$m\vec{a} = m\frac{\Delta\vec{v}}{\Delta t} = \frac{\Delta\vec{p}}{\Delta t} \tag{8.22}$$

or

$$\Delta\vec{p} = m\vec{a}\,\Delta t. \tag{8.23}$$

From Eq. 8.6 we know that $\Sigma\vec{F} = m\vec{a}$, and so Eq. 8.23 becomes

$$\Delta\vec{p} = \left(\Sigma\vec{F}\right)\Delta t \quad \text{(constant force)}. \tag{8.24}$$



If we compare this to the momentum law ($\Delta\vec{p} = \vec{J}$, Eq. 4.18), we see that the impulse delivered by the forces to the object is

$$\vec{J} = \left(\Sigma\vec{F}\right)\Delta t \quad \text{(constant force)}. \tag{8.25}$$

This equation, called the **impulse equation,** states that the impulse delivered to an object—the change in an object's momentum—during a time interval Δt is equal to the product of the vector sum of the forces exerted on the object and the duration of the time interval. Equation 8.24 shows that the longer a force is exerted, the smaller it has to be to accomplish a given change in the momentum of the object. This is why, in the bicycling example discussed in Section 8.1, the force of impact is less when you hit the mattress instead of the concrete wall. Likewise, it hurts less to catch a ball (that is to say, bring the ball to rest) with a padded glove than without one. And, by holding out your hand in front of you and then drawing it back just as the ball strikes your glove, you can further increase Δt and thus reduce the force required to slow the ball to a stop.

Figure 8.20 The impulse delivered by a force is equal to the area under the $F_x(t)$ curve, as shown here for (*a*) a constant force and (*b*) a force that varies with time.

(*a*) Impulse delivered by constant force exerted on object

(*b*) Hand shoves cart, exerting force that varies with time

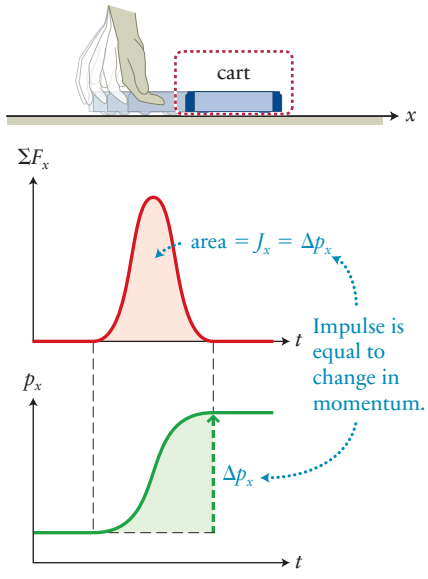


Figure 8.20*a* shows a force-versus-time graph for an object subject to constant forces whose vector sum is equal to F_0. The impulse delivered during a time interval Δt is equal to the shaded rectangular area under the $F_x(t)$ curve—the width Δt times the height F_0.

So far in this discussion, the impulse-delivering forces we've looked at have been *constant* forces. However, the relationship between impulse and area under the $F_x(t)$ curve holds not only when $\Sigma\vec{F}$ is constant. Just as we found, in Section 3.8, that the area under the $a_x(t)$ curve of an object yields the change in velocity (Eq. 3.27, $\Delta v_x = \int_{t_i}^{t_f} a_x(t)dt$), we calculate for the impulse delivered by an arbitrary force $\Sigma\vec{F}$ that varies with time

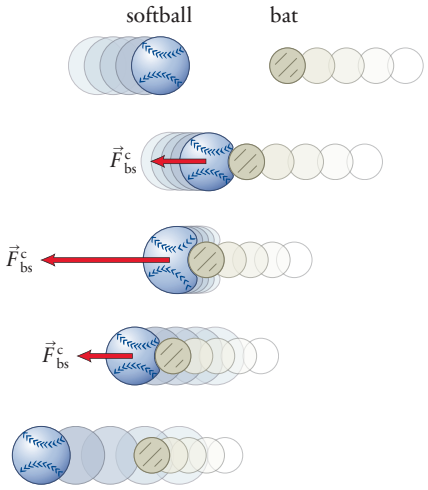
$$\Delta\vec{p} = \vec{J} = \int_{t_i}^{t_f} \Sigma\vec{F}(t)dt \quad \text{(time-varying force)}. \tag{8.26}$$

You can obtain this equation by integrating Eq. 8.4. You can also convince yourself of this result either by applying to force the procedure we applied to acceleration in Section 3.8 or by multiplying the left and right sides of Eq. 3.27 by the inertia m of the object.

Figure 8.20*b* shows the momentum of a cart getting a shove. The impulse delivered by the hand to the cart is equal to the change in momentum $\Delta\vec{p}$ shown in the figure. The force exerted by the hand on the cart is also shown in Figure 8.20*b*. This curve is obtained by applying what we know from Eq. 8.4 and taking the derivative of the $p_x(t)$ curve in Figure 8.20*b*. As the hand begins pushing, the force increases and peaks. Then, as the

QUANTITATIVE TOOLS

hand stops pushing, the force decreases to zero. The impact of a bat on a ball varies in a similar way with time, albeit much more rapidly (Figure 8.21). In general, the impulse delivered by a time-varying force during a given time interval is equal to the area under the $F_x(t)$ curve during that time interval (Eq. 8.26 and Figure 8.20*b*).



If the vector sum of the forces exerted on the object is zero, $\Sigma\vec{F} = \vec{0}$, the object is in translational equilibrium. Equation 8.26 then tells us that the momentum of the object does not change

$$\Delta\vec{p} = \vec{0} \quad \text{(translational equilibrium)}. \tag{8.27}$$

In words, the momentum of an object in translational equilibrium does not change.

8.19 (*a*) A feather and a brick are falling freely in an evacuated tube. Is the magnitude of the gravitational force exerted by Earth on the feather larger than, smaller than, or equal to that exerted by Earth on the brick? (*b*) Suppose equal forces of 10 N are exerted on both objects for 2 s. Which object gains more momentum? (*Evacuated* means all the air has been sucked out of the tube, so that there is no air resistance to hinder the motion.)

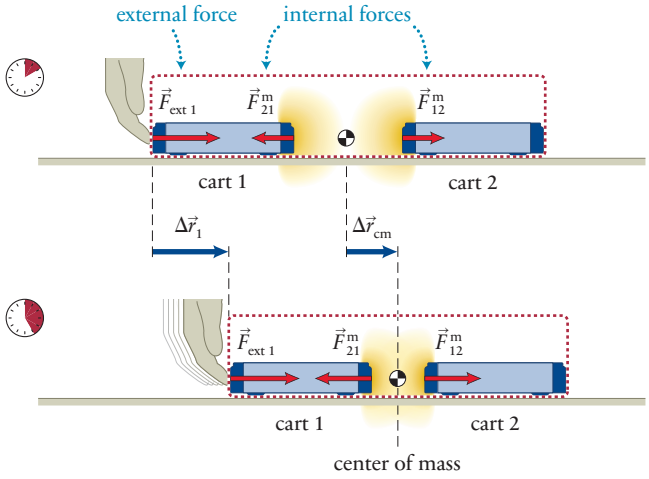


Figure 8.21 As a bat strikes a ball, the magnitude of the force exerted by the bat on the ball increases as the ball deforms, peaks at the instant the ball and bat have zero relative velocity, and finally decreases back to zero as the ball regains its shape and leaves the bat.

8.11 Systems of two interacting objects

So far we have considered only the very simple case of a single object subject to a force. In this section we look at a system of two interacting objects. For such systems, it is useful to make a distinction between forces exerted from inside the system and forces exerted on the system from outside. The former are called *internal forces*, the latter *external forces*. In Figure 8.22, two carts equipped with repelling magnets move on a track while cart 1 gets a push. Because of the magnetic repulsion, the carts never touch each other; instead, cart 2 accelerates to the right when cart 1 approaches. If we choose the two carts as our system, the forces the carts exert on each other are internal, and the push exerted on cart 1 is external.

Figure 8.22 Two carts with repelling magnets moving under the influence of an external force exerted on cart 1.

The momentum of the two-cart system is

$$\vec{p} = \vec{p}_1 + \vec{p}_2. \tag{8.28}$$

Differentiating this equation with respect to time and substituting the vector sum of the forces for each dp/dt term (Eq. 8.4) give

$$\frac{d\vec{p}}{dt} = \frac{d\vec{p}_1}{dt} + \frac{d\vec{p}_2}{dt} = \Sigma\vec{F}_1 + \Sigma\vec{F}_2. \tag{8.29}$$

The vector sum of the forces exerted on cart 1 consists of two parts: the external force exerted on cart 1 and an internal force exerted by cart 2 on cart 1 (due to the magnetic repulsion):

$$\Sigma\vec{F}_1 = \vec{F}_{\text{ext }1} + \vec{F}^{\text{m}}_{21}. \tag{8.30}$$

Because no external force is exerted on cart 2, the vector sum of the forces exerted on it is

$$\Sigma\vec{F}_2 = \vec{F}^{\text{m}}_{12}. \tag{8.31}$$

Substituting Eqs. 8.30 and 8.31 into the right side of Eq. 8.29 gives

$$\frac{d\vec{p}}{dt} = \vec{F}_{\text{ext }1} + \vec{F}^{\text{m}}_{21} + \vec{F}^{\text{m}}_{12}. \tag{8.32}$$

Because $\vec{F}^{\text{m}}_{12}$ and $\vec{F}^{\text{m}}_{21}$ form an interaction pair, we have $\vec{F}^{\text{m}}_{12} = -\vec{F}^{\text{m}}_{21}$, and so

$$\frac{d\vec{p}}{dt} = \vec{F}_{\text{ext }1}. \tag{8.33}$$

Equation 8.33 shows that only the external force exerted on cart 1 changes the momentum of the system. The internal forces do not have any effect on the momentum of the system.

Using the definition of center-of-mass velocity from Section 6.6, we have $\vec{p} = m\vec{v}_{\text{cm}}$, with $m = m_1 + m_2$. Because the inertia m of the system remains constant in the interaction, we have

$$\frac{d\vec{p}}{dt} = \frac{d(m\vec{v}_{\text{cm}})}{dt} = m\frac{d\vec{v}_{\text{cm}}}{dt} \equiv m\vec{a}_{\text{cm}} \tag{8.34}$$

and hence we can rewrite Eq. 8.33 as simply

$$\vec{F}_{\text{ext }1} = m\vec{a}_{\text{cm}} \tag{8.35}$$

or

$$\vec{a}_{\text{cm}} = \frac{\vec{F}_{\text{ext }1}}{m}. \tag{8.36}$$

Equation 8.36 is the equation of motion for the center of mass of the system. In words:

The center of mass of a two-object system accelerates as though both objects were located at the center of mass and the external force were exerted at that point.

You can now begin to see the power of the center-of-mass concept. Although we cannot determine the acceleration of the individual carts

without knowing more about the magnetic interaction, Eq. 8.36 allows us to calculate the motion of their center of mass *regardless* of the details of the magnetic interaction. As you will see in the next section, this is true not just for a system of two carts subject to a single external force, but even for a system of many interacting objects subject to many external forces, regardless of the interactions within the system and regardless of where on the system the external forces are exerted.

8.12 Systems of many interacting objects

With the analysis of a system comprising two objects under our belt, we are ready to look at the more complicated case of a system in which there are more than two objects. As in the preceding section, we begin by differentiating the momentum of the system with respect to time:

$$\frac{d\vec{p}}{dt} = \frac{d\vec{p}_1}{dt} + \frac{d\vec{p}_2}{dt} + \cdots = \Sigma\vec{F}_1 + \Sigma\vec{F}_2 + \cdots, \tag{8.37}$$

where $\vec{p}_1, \vec{p}_2, \cdots$ are the momenta of the individual objects in the system and $\Sigma\vec{F}_1, \Sigma\vec{F}_2, \cdots$ are the vector sums of the forces exerted on each of them. Each of these sums has two parts: one due to internal interactions and one due to external interactions. For object 1, for example, we have a sum of internal forces and a sum of external forces exerted on it:

$$\Sigma\vec{F}_1 = \Sigma\vec{F}_{\text{ext }1} + \Sigma\vec{F}_{\text{int }1} \tag{8.38}$$

and we can write similar expressions for all the other objects. Therefore the right side of Eq. 8.37 consists of a sum of external and internal forces:

$$\frac{d\vec{p}}{dt} = \Sigma(\vec{F}_{\text{ext }1} + \vec{F}_{\text{ext }2} + \cdots) + \Sigma(\vec{F}_{\text{int }1} + \vec{F}_{\text{int }2} + \cdots). \tag{8.39}$$

All internal forces drop out of Eq. 8.39, however. To see why, consider the case in which there are no external forces. Then the right side of Eq. 8.39 reduces to the sum of all internal forces:

$$\frac{d\vec{p}}{dt} = \Sigma(\vec{F}_{\text{int }1} + \vec{F}_{\text{int }2} + \cdots). \tag{8.40}$$

In this case, however, the system is isolated (because no external forces are exerted on it), and so we know that its momentum does not change. Therefore $d\vec{p}/dt = \vec{0}$ and Eq. 8.40 becomes

$$\vec{0} = \Sigma(\vec{F}_{\text{int }1} + \vec{F}_{\text{int }2} + \cdots). \tag{8.41}$$

In words, all the internal forces add up to zero! Therefore all of them drop out of the right side of Eq. 8.39, and the time rate of change of the momentum of the system is the sum of the external forces:

$$\frac{d\vec{p}}{dt} = \Sigma(\vec{F}_{\text{ext }1} + \vec{F}_{\text{ext }2} + \cdots) \equiv \Sigma\vec{F}_{\text{ext}}, \tag{8.42}$$

where $\Sigma\vec{F}_{\text{ext}}$ is the vector sum of all of the external forces exerted on the system. (See also the box "Cancellation of internal forces" on page 270.)

Cancellation of internal forces

There is another way to see that internal forces always add to zero. We consider here a system consisting of three particles, but the proof can be extended to any number of particles.

Each particle is subject to forces from the other two particles and to an external force:

$$\Sigma\vec{F}_1 = \Sigma\vec{F}_{\text{ext }1} + \vec{F}_{21} + \vec{F}_{31}$$
$$\Sigma\vec{F}_2 = \Sigma\vec{F}_{\text{ext }2} + \vec{F}_{12} + \vec{F}_{32}$$
$$\Sigma\vec{F}_3 = \Sigma\vec{F}_{\text{ext }3} + \vec{F}_{13} + \vec{F}_{23}.$$

Summing up all the forces, we get

$$\Sigma\vec{F}_1 + \Sigma\vec{F}_2 + \Sigma\vec{F}_3$$
$$= \Sigma\vec{F}_{\text{ext }1} + \Sigma\vec{F}_{\text{ext }2} + \Sigma\vec{F}_{\text{ext }3} + (\vec{F}_{12} + \vec{F}_{21})$$
$$+ (\vec{F}_{13} + \vec{F}_{31}) + (\vec{F}_{32} + \vec{F}_{23}). \qquad (1)$$

Remember, however, that two interacting particles exert on each other forces that are equal in magnitude but opposite in direction (Eq. 8.15). This means that the following equalities must hold:

$$\vec{F}_{12} = -\vec{F}_{21}$$
$$\vec{F}_{13} = -\vec{F}_{31}$$
$$\vec{F}_{32} = -\vec{F}_{23}.$$

So each term in parentheses in Eq. 1 vanishes, and only the external forces remain:

$$\Sigma\vec{F}_1 + \Sigma\vec{F}_2 + \Sigma\vec{F}_3$$
$$= \Sigma\vec{F}_{\text{ext }1} + \Sigma\vec{F}_{\text{ext }2} + \Sigma\vec{F}_{\text{ext }3}.$$

Using the definition of center-of-mass velocity again, we have $\vec{p} = m\vec{v}_{\text{cm}}$, where $m = m_1 + m_2 + \cdots$, so that

$$\frac{d\vec{p}}{dt} = \frac{d(m\vec{v}_{\text{cm}})}{dt} = m\frac{d\vec{v}_{\text{cm}}}{dt} \equiv m\vec{a}_{\text{cm}}. \qquad (8.43)$$

After substituting Eq. 8.43 into Eq. 8.42, we obtain the same result as for the two-object nonisolated system:

$$\Sigma\vec{F}_{\text{ext}} = m\vec{a}_{\text{cm}}. \qquad (8.44)$$

Now, however, this expression applies to many objects and many external forces.* What this result means is the following: If external forces are exerted on the objects in a many-object system, the system's center of mass moves as though all the objects in the system were concentrated at the center of mass and all external forces were exerted at that point.

The equation of motion for the center of mass of a nonisolated system is thus

$$\vec{a}_{\text{cm}} = \frac{\Sigma\vec{F}_{\text{ext}}}{m}. \qquad (8.45)$$

Note the surprising similarities between the equations for a single object (Eqs. 8.4 and 8.6),

$$\frac{d\vec{p}}{dt} = \Sigma\vec{F} \quad \text{and} \quad \Sigma\vec{F} = m\vec{a}, \qquad (8.46)$$

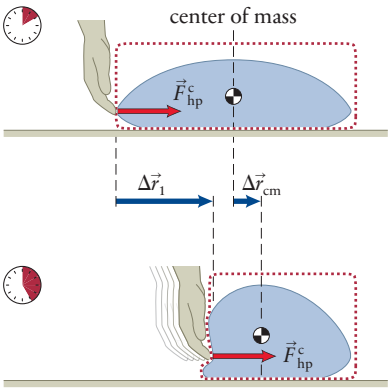
and those for the center of mass of a system of interacting objects (Eqs. 8.42 and 8.44),

$$\frac{d\vec{p}}{dt} = \Sigma\vec{F}_{\text{ext}} \quad \text{and} \quad \Sigma\vec{F}_{\text{ext}} = m\vec{a}_{\text{cm}}. \qquad (8.47)$$

*Equation 8.44 is less general than Eq. 8.42. The latter is always true, but the former holds only if the inertia m of the system is not changing. Equation 8.44 cannot be used, for instance, to calculate the acceleration of a rocket where the burning and high-speed ejection of fuel result in an appreciable change in the rocket's inertia.

The most significant difference between Eqs. 8.6 and 8.44 is that instead of the acceleration $\vec{a}$ of a single object, Eq. 8.44 contains the center-of-mass acceleration $\vec{a}_{cm}$ of the system. This subtle but very important difference is what makes it possible to apply this analysis to everyday objects. Any object can be regarded as a system of interacting particles; after all, objects are made up of many interacting atoms. Thus all the relationships we just derived apply to macro-sized objects.

One interesting application is to macro-sized objects that deform easily. For example, imagine pushing a down pillow (**Figure 8.23**). When you begin pushing on one edge of the pillow, your hand deforms the side it touches, meaning that part of the pillow is accelerating. While your hand is accelerating that side of the pillow, the other side of the pillow doesn't move at all. In other words, different parts of the pillow have different instantaneous velocities and different instantaneous accelerations. It therefore makes no sense, while deformation is taking place, to speak of *the* acceleration $\vec{a}$ of the pillow, and Eqs. 8.46 cannot be applied. On the other hand, we can always use Eqs. 8.47 to describe the motion of the pillow's center of mass. In other words, the momentum $\vec{p}$ of the pillow, the acceleration $\vec{a}_{cm}$ of its center of mass, and the vector sum of the forces exerted on it are still well-defined quantities.



Perhaps the most remarkable aspect of this result is that we can always apply Eqs. 8.42 and 8.44 regardless of the internal interactions in a system. Even without any knowledge of these interactions, we can determine the motion of the center of mass of the pillow. What we give up by not considering the internal interactions is the ability to determine how the system deforms or what the motions of the different parts of the system are when the external force is exerted. In Figures 8.22 and 8.23, for example, we can determine only the displacement $\Delta\vec{r}_{cm}$ of the center of mass, not the displacement $\Delta\vec{r}_1$ of the point where the external force is exerted on the system, or the displacement of any other point.

The difference between Eqs. 8.46 and 8.47 vanishes when we consider a single object and ignore any deformation in it—that is to say, if we consider a **rigid object.** Although I argued in Section 8.6 that no object is truly rigid, most objects can be treated as being rigid for the purpose of describing their motion. For example, imagine pushing a stalled car toward the side of the road. For motion in one dimension, the front of the car moves the same way the back does—the minute compression of the car while your hands are pushing it is negligible. If you displace the back of the car by, say, 10 m, you can be pretty sure that the front of the car is also displaced by 10 m (give or take a fraction of the width of a hair). *All* parts of the car get displaced by 10 m in the same direction, and so the velocity and acceleration are the same for all parts of the car. For rigid objects we do not need to take into account any internal interactions or any difference in the displacement of various parts of the object.

Only for *deformable objects* (or for systems consisting of two or more rigid objects that can move relative to one another, like the two magnetically repelling carts in Figure 8.22) do you have to use the results derived in the last two sections.

8.20 (*a*) Show that Eqs. 8.47 reduce to Eqs. 8.46 when you consider a system of just one object. (*b*) Follow the procedure used to get from Eq. 8.21 to Eq. 8.24 for a system of many interacting objects.

Figure 8.23 As the external force exerted by the hand displaces a down pillow, the pillow deforms, and so different parts of the pillow are displaced by different amounts. For objects that deform, it makes no sense to speak of "the displacement" or "the acceleration" of the object. However, it does makes sense to speak of the displacement or the acceleration of the center of mass.

Chapter Summary

Characteristics of forces (Sections 8.1, 8.2, 8.3, 8.7)

Concepts When an object participates in one interaction only, the **force** exerted on the object is given by the time rate of change in the object's momentum.

A **contact force** is a force that one object exerts on another object only when the two objects are in physical contact.

A **field force** is a force (such as gravity) that one object exerts on another object without the requirement that the two objects be in physical contact.

When two objects interact, the forces they exert on each other form an **interaction pair,** and these forces have equal magnitudes but opposite directions.

Quantitative Tools The SI unit of force is the **newton** (N):

$$1\ \text{N} = 1\ \text{kg}\cdot\text{m/s}^2. \tag{8.9}$$

For an interaction pair of forces,

$$\vec{F}_{12} = -\vec{F}_{21}. \tag{8.15}$$

Some important forces (Sections 8.6, 8.8, 8.9)

Concepts A taut, flexible object (such as a spring, rope, or thread), when subjected to equal and opposite *tensile forces* applied at either end, experiences along its length a *stress* called **tension.** If the object is very light, the tension is the same everywhere in it.

Hooke's law relates the force that a spring exerts on a load to the distance the spring is stretched (or compressed) from its relaxed position.

Quantitative Tools The x component of the force of gravity exerted on an object of inertia m near Earth's surface is

$$F^G_{\text{E}o\,x} = -mg, \tag{8.17}$$

where the minus sign indicates that the force is directed downward.

Hooke's law: If a spring is stretched (or compressed) by a *small* distance $x - x_0$ from its unstretched length x_0, the x component of the force it exerts on the load is

$$(F_{\text{by spring on load}})_x = -k(x - x_0), \tag{8.20}$$

where k is called the **spring constant** of the spring.

Effects of force (Sections 8.1, 8.4, 8.5, 8.7)

Concepts The vector sum of the forces exerted on an object is equal to the time rate of change of the momentum of the object.

The **equation of motion** for an object relates the object's acceleration to the vector sum of the forces exerted on it.

Newton's laws of motion describe the effects forces have on the motion of objects.

If an object is at rest or moving with constant velocity, it is in **translational equilibrium.** In this case, the vector sum of the forces exerted on it is equal to zero.

A **free-body diagram** for an object is a sketch representing the object by a dot and showing all the forces exerted *on* it.

Quantitative Tools Vector sum of forces exerted on an object:

$$\Sigma\vec{F} \equiv \frac{d\vec{p}}{dt}. \tag{8.4}$$

Equation of motion:

$$\vec{a} = \frac{\Sigma\vec{F}}{m}. \tag{8.7}$$

If the inertia m of an object is constant, Newton's second law is usually written as

$$\Sigma\vec{F} = m\vec{a}. \tag{8.6}$$

For two interacting objects, 1 and 2, Newton's third law of motion states that

$$\vec{F}_{12} = -\vec{F}_{21}. \tag{8.15}$$

Impulse (Section 8.10)

Concepts The **impulse** $\vec{J}$ produced by forces exerted on an object is the product of the vector sum of the forces and the time interval over which the forces are exerted. The impulse delivered to the object is also equal to the change in its momentum.

Quantitative Tools For a constant force,

$$\Delta\vec{p} = \vec{J} = \left(\Sigma\vec{F}\right)\Delta t. \qquad (8.24, 8.25)$$

For a time-varying force,

$$\Delta\vec{p} = \vec{J} = \int_{t_i}^{t_f} \Sigma\vec{F}(t)\,dt. \qquad (8.26)$$

System of interacting objects (Sections 8.11, 8.12)

Concepts The center of mass of a system of objects accelerates as though all the objects were located at the center of mass and the external force were applied at that location.

Quantitative Tools Acceleration of a system of objects:

$$\vec{a}_{cm} = \frac{\Sigma\vec{F}_{ext}}{m}. \qquad (8.45)$$

Questions and Problems

Dots indicate difficulty level of problems: • = *easy*, •• = *intermediate*, ••• = *hard*; CR = *context-rich problem.*

8.1 Momentum and force

1. A car merges onto a freeway, accelerating from 60 km/h to 80 km/h. As it does this, a bus passes by in the fast lane, travelling at a constant 100 km/h. Which vehicle has the greater magnitude of the vector sum of forces acting on it? •
2. You wish to move a crate. (*a*) Is there a minimum value for the magnitude of the pushing force you have to exert to set the crate in motion? (*b*) Is there a minimum value for the magnitude of the vector sum of forces that must be exerted on the crate to set it in motion? •
3. Sketch the $\Sigma F_x(t)$ curve for the vector sum of forces exerted on the object whose x component of momentum is plotted in Figure P8.3. Curve sections are numbered for reference. ••

Figure P8.3

4. The x component of the vector sum of forces exerted on a cart moving on a low-friction track is measured in the laboratory with the aid of a spring-loaded sensor and a monitoring computer. From the data in the table, sketch the $\Sigma F_x(t)$ curve of the cart and use your graph to estimate the change in the cart's momentum. ••

F (N)	t (s)
0.00	0.00
0.15	0.020
0.32	0.040
0.50	0.060
0.57	0.080
0.37	0.10
0.21	0.12
0.11	0.14
0.070	0.16
0.040	0.18

5. If a single known force is exerted on an object of unknown initial velocity for a certain time interval, you know the change in the object's momentum. However, you don't know its change in kinetic energy. Why not? •••
6. Consider a coal mining cart being loaded with coal as it moves along a horizontal track. Suppose that a tractor exerts a constant horizontal force on this cart. Is there any situation in which the cart-coal system would not accelerate? •••

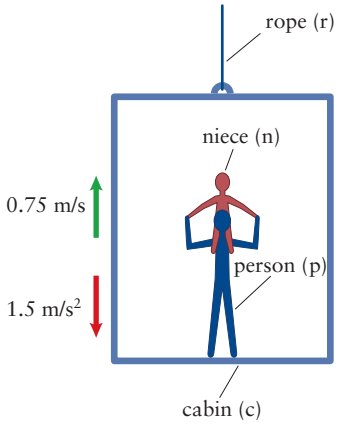
8.2 The reciprocity of forces

7. A worker pushes a box in a factory. In each case, decide which force has the greater magnitude: the force exerted by the worker on the box or the force exerted by the box on the worker. (*a*) The box is heavy and does not move no matter how hard the worker pushes. (*b*) Some contents are removed, and now when pushed the box slides across the floor at constant speed. (*c*) The worker pushes harder, and the box accelerates. •

8. In many science fiction movies, someone is portrayed moving something with her or his mind—an amazing feat called *telekinesis*. What does your knowledge of forces predict about the effect of a telekinetic event on the gifted person? •
9. You jump into the air from a level floor. Which of the following are exerting a force on you: (*a*) the floor, (*b*) the Earth, (*c*) the air, (*d*) your feet? ••
10. During a tennis volley, a ball that arrives at a player at 40 m/s is struck by the racquet and returned at 40 m/s. The other player, realizing that the ball is out of bounds, catches it in her hand. Assuming the time interval of contact is the same in both cases, compare the force exerted by the first player's racquet on the ball with the force exerted by the second player's hand on the ball. ••

8.3 Identifying forces

11. Two soccer players kick two identical balls at the same time. Player 1 sends his ball at an impressive 90 km/hr at an angle of 30° above the horizontal. Player 2 kicks at 70 km/hr at 45°. Once in mid-air, which ball has a larger force acting on it? •
12. The force of friction is one of the most common forces that affects our everyday lives, and there are many situations where we either want to minimize or maximize it. Consider a children's playground and think of a situation where a large force of friction is important, and also another situation where a small force of friction is desirable. •
13. A boy bounces on a trampoline. When the boy is up in the air at the highest point, can you say that the total force on him is zero? ••
14. (*a*) Can an object ever exert both a contact force and a field force on another object? (*b*) Can an object ever exert a contact force on something without exerting a field force on that same object? ••



8.4 Translational equilibrium

15. You and two other friends are pushing a car over the rough road ahead. A physicist observing the car's motion claims there is no net force acting on the car. Explain. •
16. You are discussing physics homework with a friend while the two of you are riding your bikes. Distracted, you collide with a parked car. The car doesn't move. Your friend says, "Of course not! The force of the collision wasn't enough to overcome the inertia of the car." How do you respond? •
17. What interaction does a bathroom (spring) scale actually measure? ••
18. A table sits on the floor, and a vase containing water and flowers sits on top of the table. All objects are at rest. Identify all forces exerted on the table, and describe how these forces are related. ••

8.5 Free-body diagrams

19. You want to climb up a rope attached to a tree branch overhead. You test the strength of the rope by holding it while slowly lifting your feet off the ground; the rope holds your weight. However, as you start to climb rapidly up the rope, it suddenly breaks. Your weight has not changed, so why did the rope break? •
20. When you are standing motionless on the ground, your feet exert a force on Earth. Why doesn't Earth move away from you? ••
21. You push on a crate, and it starts to move—but you don't. Draw a free-body diagram for you and one for the crate; show only the horizontal forces. Then use the diagrams and your knowledge about forces and interactions to explain why the crate moves but you don't. ••
22. A ball falling near the surface of the Earth where air friction is not negligible eventually slows down to a constant "terminal" velocity. How is that possible given that frictional force increases with increasing velocity? ••
23. You are carrying your 3-year-old niece on your shoulders in an elevator cabin that is moving upward with velocity 0.75 m/s and constant downward acceleration of 1.5 m/s^2 (Figure P8.23*). Your inertia is 60 kg, your niece's inertia is 25 kg, and the cabin's inertia is 95 kg. (*a*) Draw free-body diagrams for the elevator cabin, your niece, and yourself, labeling the forces using the notation introduced in section 8.5. Make sure the lengths of the force vectors are appropriate to the magnitudes of the forces. (*b*) State the magnitudes of as many forces as possible, and identify all the forces that form interaction pairs. Explain briefly how you obtained these magnitudes. •••

Figure P8.23

8.6 Springs and tension

24. A delivery person in an elevator is holding a package by an elastic cord. (Don't ask why.) (*a*) What happens to the length of the cord when the elevator accelerates upward? Draw the free-body diagram for the package in this case. (*b*) What happens to the cord length when the elevator slows to a stop after its ascent? Draw the free-body diagram for the package in this case. •
25. Suppose a rope that is hanging by one end from the ceiling has a large inertia. Is the tension in the rope uniform throughout the length? ••
26. Walking beside a pasture, you and a fellow student see a farmer pulling a mule with a rope and getting nowhere. Your friend says, "The force with which the mule is

pulling on the rope has the same magnitude as the force with which the farmer is pulling on the rope, but the two forces point in opposite directions. Because the two forces cancel, the tension in the rope is zero." How do you respond? ●●

27. In a game of tug of war, the blue team is beating the red team, and the red team is accelerating toward the mud pit between the two teams. Which has the greater magnitude, if either: the force the blue team exerts on the rope or the force the red team exerts on the rope? Assume that the gravitational force exerted on the rope is negligible compared with the forces exerted by the two teams on the rope. ●●

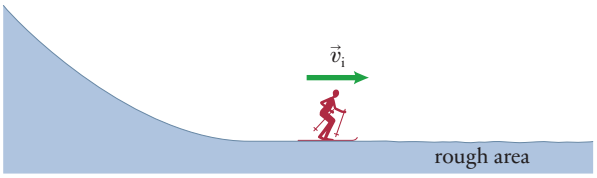
28. The standard coupling between railroad cars must be capable of withstanding the maximum tensile force exerted on any coupling in a given train. (*a*) If a locomotive is pulling ten cars and speeding up, on which coupling is the greatest tensile force exerted? (*b*) Is this tensile force due to stretching or compression? (*c*) If the locomotive is slowing the train down, on which coupling is the greatest tensile force exerted? (*d*) Is this tensile force due to stretching or compression? ●●

8.7 Equation of motion

29. A proton (inertia 1.67×10^{-27} kg) and an electron (inertia 9.11×10^{-31} kg) are being separately subjected to an electric force of 3.2×10^{-14} N. Compare their ensuing accelerations. ●

30. An object moving along the x-axis experiences a constant force in its direction of motion, $F_x = 56$ N. At $t = 1.2$ s, the object is moving at 2.0 m/s and at $t = 3.5$ s it is moving at 2.8 m/s. What is the inertia of the object? ●

31. Using this chapter, is it possible to figure out an object's past motion if you know its present position and velocity and the history of all the forces exerted on it? ●●



32. The force exerted by expanding gases is what propels a shell out of a gun barrel. Suppose a force that has an average magnitude F propels the shell so that it has a speed v at the instant it reaches the end of the barrel. What magnitude force is required to double the speed of the shell in the same gun? ●●

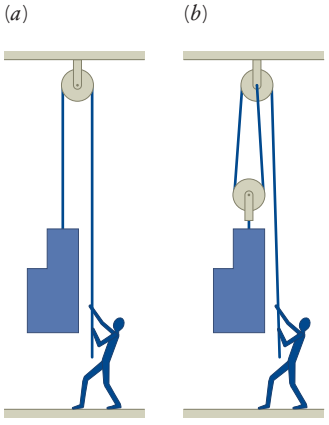
33. A 50-kg pneumatic hammer is fitted with a shock absorber at the top to lessen the impact on the worker. The vertical displacement of the hammer as a function of time is given by $x(t) = at^2 - bt^3$ (during the hammer's bounce), where $a = 15$ m/s^2 and $b = 20$ m/s^3. The positive x axis is directed upward. (*a*) Write an expression for the x component of the vector sum of forces exerted on the hammer as a function of time. (*b*) At which values of t is the x component of the vector sum of forces on the hammer positive, at which values of t is it negative, and at which values of t is it zero? ●●

34. You push a 30 kg shopping cart initially at rest (loaded with groceries) with a constant 12-N force. How far does it travel after pushing it for 4.5 s? ●●

35. In Figure P8.35, a 55-kg skier heads down a slope, reaching a speed of 27 km/h. They then slide across a horizontal snow field but hit a rough area. Assume the snow before the rough area is so slippery that you can ignore any friction between the skier and the snow. However the rough area exerts a significant constant friction force. If the skier comes to rest after travelling 50 m across the rough area, what is the magnitude of the friction force? ●●

Figure P8.35

36. A 2.34-kg cart on a long, level, low-friction track is heading for a small electric fan at 0.23 m/s. The fan, which was initially off, is turned on. As the fan speeds up, the magnitude of the force it exerts on the cart is given by at^2, where $a = 0.0200$ N/s^2. What is the speed of the cart 3.5 s after the fan is turned on? After how many seconds is the cart's velocity zero? ●●●



8.8 Force of gravity

37. Two blocks of the same inertia (10 kg) but different sizes are falling freely. Compare the force exerted by the Earth on the two blocks. ●

38. Estimate the magnitude of the force of gravity exerted on (*a*) a packet of sugar, (*b*) a cup of water, (*c*) a packed carry-on suitcase, (*d*) an adult gorilla, and (*e*) a midsize car. ●

39. The magnitude of the gravitational force exerted on the piano in Figure P8.39 is 1500 N. With how much force do you have to pull on the rope in order to hold up the piano (*a*) with the single pulley and (*b*) with the double pulley? ●

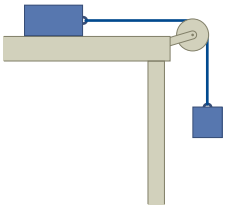


Figure P8.39

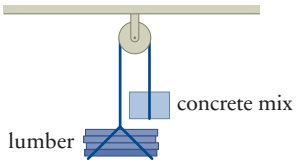
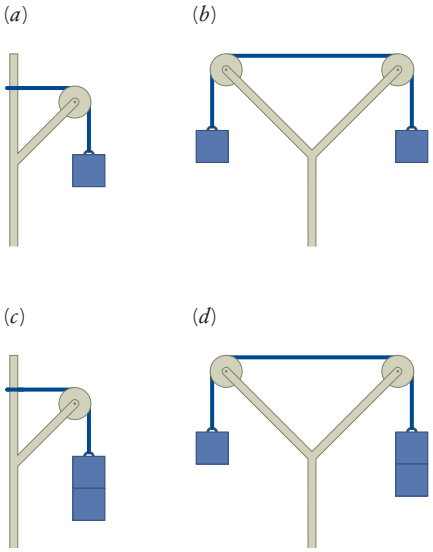
40. The piano in Figure P8.39 is being lowered with an acceleration of magnitude exactly $g/8$. To maintain this acceleration, with what force magnitude must the person pull on the rope (*a*) with the single pulley and (*b*) with the double pulley? ●●



41. If the force of gravity exerted by Earth on a fully suited astronaut at Earth's surface is 1960 N, what is the magnitude of the gravitational force exerted on her (*a*) on Jupiter, where the acceleration due to gravity is 25.9 m/s^2, and (*b*) on the Moon, where the acceleration due to gravity is 1.6 m/s^2? ●●
42. You are collecting water from a well by lowering a bucket on a rope. The inertia of the empty bucket is 0.72 kg, and the inertia of the rope is negligible. (*a*) If you lower the empty bucket with a downward acceleration of 4.8 m/s^2, what is the tension in the rope? (*b*) You now pull the filled bucket, with total inertia 6.6 kg, back to the top of the well. If the maximum tension that the rope can support is 100 N, what is the maximum upward acceleration for the bucket? ●●
43. Figure P8.43 shows two blocks, one of which is placed on a low-friction table, and supports, by means of a massless rope that runs over a low-friction pulley, the other block, which is suspended in mid-air. If you hold the hanging block, and then release it, how big an inertia should this block have for the system to slide? What would the acceleration of the system be, in terms of *g*, *m*, and M? ●●

Figure P8.43

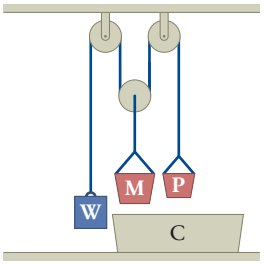


44. Assume that the block on the table in Figure P8.43 has twice the inertia of the hanging block. (*a*) You give the block on the table a push to the right so that it starts to move. If the magnitude of the frictional force exerted by the table on the block is half the magnitude of the gravitational force exerted on the hanging block, what is the acceleration of the hanging block after you have stopped pushing the block on the table? (*b*) What would this hanging-block acceleration be if you had pushed the block on the table to the left instead? Consider only a short time interval after you stop pushing. ●●
45. Consider figure P8.43. Let the inertia of the block on the table be M and that of the hanging bock be M/4. If the coefficient of kinetic friction between the table and the block is 0.2, calculate the tension in the rope and the acceleration of the hanging block. ●●
46. A bag of concrete mix is tied to one end of a rope that is looped over a pulley attached to the ceiling, and the other end of the rope is tied to a pallet of lumber (Figure P8.46). The concrete mix has a greater inertia than the lumber. When both loads are released from rest so that the system is free to move, compare the tension in the rope with the magnitudes of the gravitational forces exerted by Earth on the lumber and on the concrete mix. Ignore any friction in the pulley. ●●

Figure P8.46

47. All blocks in Figure P8.47 are identical and you can ignore any friction in the pulleys. Rank the configurations in increasing order of tension in the rope. (Hint: Use free-body diagrams.) ●●

Figure P8.47



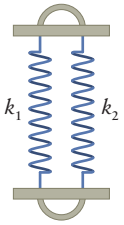
48. Picture an object in free fall. If the leading face of the object (which means the face closest to the ground) has a large surface area, air resistance becomes important. For low speeds, the force due to air resistance may be approximated as proportional to the object's velocity according to the expression $\vec{F}^{a} = -b\vec{v}$, where *b* is a number that depends on the shape and volume of the object and on the density of the air. (*a*) Show that, for an object of inertia *m*, there is a limiting speed (called the *terminal speed*) given by $v_t = mg/b$. (*b*) Show that, if the object is released from rest, its speed as a function of time is given by

$$v(t) = v_t[1 - e^{-(b/m)t}].$$

(*c*) What are the units of m/b? Sketch a graph of *v* as a function of time, with the horizontal axis in units of multiples of m/b. ●●●
49. At a munitions factory, chemicals M and P have to be added to a vat containing chemical C. Chemicals M and

P have to be added simultaneously to prevent an accidental detonation. Your task, as the chemical engineer in charge, is to come up with a way of doing this, and you devise the pulley scheme shown in Figure P8.49, where block W is a counterweight whose inertia controls the speed at which the buckets containing chemicals M and P move. The idea is that when a strap holding block W at rest is released, the block rises and the buckets containing M and P descend into the vat. In order to have the two buckets have an identical acceleration of magnitude $g/3$, what must be the ratios of the inertias m_W, m_M, and m_P? Ignore any friction in the pulleys. •••

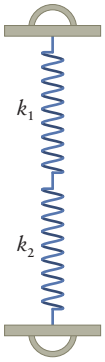
Figure P8.49



8.9 Hooke's law

50. A 66-kg person experiences a gravitational force of about 660 N. Yet, if this person were to jump onto a spring scale, the scale would briefly read about 2400 N. Why does the scale register a force so much larger than the gravitational force exerted on the person? •

51. A 27-kg child stands in the center of a trampoline. (*a*) If the trampoline center is 0.32 m lower than before they got on, what is the spring constant of the trampoline? (*b*) Assuming the trampoline acts like a spring, how low would their 65-kg father sink if he stood alone in the center? •

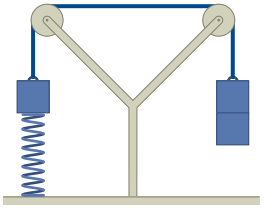


52. Two springs have spring constants k_1 and $k_2 > k_1$. Connected as shown in Figure P8.52, they act like one spring. Compute the spring constant of the combination, and determine whether it is smaller than k_1, equal to k_1, between k_1 and k_2, equal to k_2, or greater than k_2. ••

Figure P8.52

53. Two springs have spring constants k_1 and $k_2 > k_1$. Connected as shown in Figure P8.53, they act like one spring. Compute the spring constant of the combination. Is the combination smaller than k_1, equal to k_1, between k_1 and k_2, equal to k_2, or greater than k_2? ••

Figure P8.53



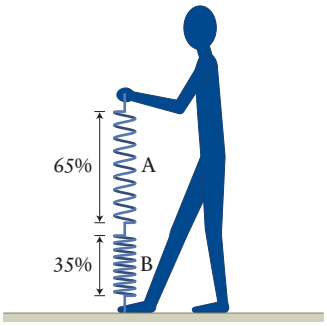
54. Two springs are hooked together end to end. When a 4.0-kg brick is suspended from one end of the combination, the combination stretches 0.15 m beyond its relaxed length. (*a*) What is the spring constant of the combination? (*b*) If the top spring stretches 0.10 m, what is the spring constant of each spring? ••

55. When a 5.0-kg box is hung from a spring, the spring stretches to 50 mm beyond its relaxed length. In an elevator accelerating upward at 2.0 m/s^2, how far does the spring stretch with the same box attached? ••

56. Suppose that when you lie on your bed, your body is supported by 30 of the springs in the mattress. Assuming that all the springs are identical and that your body presses on each spring equally, estimate their spring constant. (Experiment: Lie on your bed and see how far down you sink.) ••

57. In the modified Atwood machine shown in Figure P8.57, each of the three blocks has the same inertia m. One end of the vertical spring, which has spring constant k, is attached to the single block, and the other end of the spring is fixed to the floor. The positions of the blocks are adjusted until the spring is at its relaxed length. The blocks are then released from rest. What is the acceleration of the two blocks on the right after they have dropped a distance d? Ignore any friction in the pulleys. ••

Figure P8.57



58. Your boss hands you a bag containing four springs, A, B, C, and D, and tells you that they all have the same relaxed length. He wants you to rank them by the values of their spring constants. He locks you in a room with only the springs, a ruler, and a pad and pencil, and tells you to knock when you're done. Each spring has a hook on one end and a handgrip on the other. There is nothing in the room you can use to measure inertia.

After thinking for a few minutes, you hook springs A and B together, stand on one handgrip with your foot, and pull on the other handgrip with your hand until the

combination spring has been stretched to double its original length (Figure P8.58). You notice that spring A makes up 65% of the stretched length and spring B makes up the other 35%.

Figure P8.58

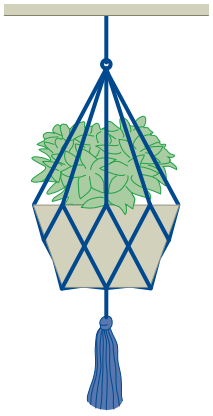
You work your way through the rest of the springs and tabulate the results:

Combination	Percent of stretched length
A/B	A 65, B 35
A/C	A 70, C 30
A/D	A 67, D 33

Based on these results, what are the numerical values in the ratio k_A: k_B: k_C: k_D? •••

59. A 5.0-kg red book is suspended from a spring attached to the ceiling of an elevator that is accelerating downward. Attaching the book causes the spring to stretch 71 mm beyond its relaxed length. You also have a yellow book of unknown inertia. When you attach the yellow book and the red one to the spring at the same time, the spring stretches 110 mm beyond its relaxed length. When the elevator is at rest, the combination of the two books stretches the spring 140 mm beyond its relaxed length. (*a*) What is the spring constant? (*b*) What is the inertia of the yellow book? (*c*) What is the elevator's acceleration? •••

8.10 Impulse



60. Use the relationship between force and impulse to explain how padded boxing gloves protect a boxer's hands. •

61. If you try to pound a nail into a board with a 2.5-kg rubber mallet, you will have less luck than if you use a 0.8-kg steel hammer. Why? •

62. In a baseball game, a batter hits the 0.150-kg ball straight back at the pitcher at 180 km/h. If the ball is traveling at 160 km/h just before it reaches the bat, what is the average force exerted by the bat on it if the collision lasts 5.0 ms? •

63. In Figure P8.63, a heavy potted plant hangs by an enveloping hanger made of heavy yarn. (*a*) If you pull slowly on the tassel at the bottom, where is the hanger most likely to break? Why? (*b*) If you yank quickly on the tassel, where is the hanger most likely to break? ••

Figure P8.63

64. Estimate the impulse delivered by a hammer to a nail being driven into a wood plank. ••

65. An 1100-kg car stops at a red light, going from 85 km/h to stationary in 20 s. (*a*) What is the impulse delivered to the car? (*b*) What is the average vector sum of forces exerted on the car? ••

66. A 2-kg block resting on a low-friction floor is subjected to the time-dependent force $F(t) = 0.5t^2$. The block starts out 1.0 m away from the origin. (*a*) What is speed of the object at $t = 2.0$ s? (*b*) What is the position of the object at $t = 2.0$ s? ••

67. Just before hitting the ground, a partially inflated 0.625-kg basketball has a speed of 3.30 m/s. Then it loses half of its kinetic energy as it bounces. (*a*) What is the ball's speed immediately after it bounces? (*b*) If the ball is in contact with the ground for 9.25 ms, what is the magnitude of the average force exerted by the ground on the ball? ••

68. A 2.3-kg ball dropped from a height of 2.0 m onto a steel plate rigidly attached to the ground bounces back to a height of 1.7 m. (*a*) What is the impulse delivered to the ball by the plate? (*b*) What is the coefficient of restitution of the collision? ••

69. A 0.050-kg egg falls off a table that is 1.0 m high and lands on a tile floor. (*a*) What is the impulse delivered to the egg by the floor? (*b*) The egg lands on its side, and at the instant of impact the part of the shell farthest from the floor is 40 mm above the floor. The collision continues until the center of mass is on the floor. Estimate the time interval over which the collision lasts. (*c*) What is the average force exerted by the floor on the egg? (*d*) If the floor were carpeted, the collision time interval might be extended by as much as a factor of four as the carpet "gives" under the egg. What would the average force exerted on the egg be then? ••

70. When it crashes into a bridge support that does not move, a car goes from 80 km/h to 0 in 1.23 m. (*a*) What is the impulse delivered to the 70-kg driver by the seat belt, assuming the belt makes the driver's motion identical to the car's motion? (*b*) What is the average force exerted by the belt on the driver? (*c*) If the driver were not wearing the seat belt and flew forward until he hit the steering wheel, which stopped him in 0.0145 s, what would be the average force exerted by the steering wheel on him? (*d*) Would he be likely to survive the crash described in part *c*? Justify your answer by comparing

the force exerted by the steering wheel on the driver to the gravitational force exerted on him. •••

71. A volleyball player serves the ball. The 0.27-kg ball was moving straight up and is at the high point of its trajectory when she hits it in a purely horizontal direction. The magnitude of the force exerted on the ball while her hand is in contact with it is given by

$$F(t)_{\text{hb}}^{\text{c}} = at - bt^2,$$

where $a = 3.0 \times 10^5$ N/s and $b = 1.0 \times 10^8$ N/s^2. Her hand is in contact with the ball for 3.0 ms. What is the magnitude of (*a*) the impulse delivered to the ball, (*b*) the average force exerted by her hand on the ball, and (*c*) the maximum force exerted by her hand on the ball? (*d*) What is the velocity of the ball immediately after her hand loses contact with it? •••

8.11 Systems of two interacting objects

72. A 70-kg student is falling toward Earth. (*a*) Draw one free-body diagram for Earth and one for the student. Assume that air resistance can be ignored. (*b*) Calculate the student's acceleration and the vector sum of forces exerted on him. (*c*) Earth's inertia is 5.97×10^{24} kg. What is the magnitude of the planet's acceleration toward the student? •

73. Box A, which has an inertia of 2 kg, and box B, which has an inertia of 3 kg, are 2.0 m apart on a low-friction floor. Box B is pushed toward box A by a steady force of 10.0 N. What is the acceleration of (*a*) box A and (*b*) the center of mass of the system before they collide? •

74. Two 0.500-kg carts are 100 mm apart on a low-friction track. You push one of the carts with a constant force of 2.00 N directed so that the cart you push moves away from the other cart. Determine the acceleration of the center of mass of the two-cart system when (*a*) the carts do not interact and (*b*) the carts are connected by a spring of spring constant $k = 300$ N/m. ••

75. A force of magnitude F is exerted on the leftmost face of two blocks sitting next to each other on a slippery surface, with two of their faces touching. The inertia of the block on the right is m, and the inertia of the block on the left is $2m$. (*a*) What is the magnitude of the acceleration of each block? (*b*) What are the magnitude and direction of the contact force the left block exerts on the right block? (*c*) What are the magnitude and direction of the contact force the right block exerts on the left block? (*d*) How do your answers to parts *a*, *b*, and *c* change if the positions of the two blocks are interchanged? ••

76. A 2.0-kg cart and an 8.0-kg cart are connected by a relaxed, horizontal spring of spring constant 300 N/m. You pull the 8.0-kg cart with some constant horizontal force. The separation between the carts increases for a short time interval, then remains constant as you continue to pull and the spring is stretched by 0.100 m. (*a*) What pulling force did you exert? (*b*) If you instead pull the 2.0-kg cart, what force must you exert to get the same stretch in the spring? ••

77. A 1500-kg truck and a 1000-kg car are parked with their rear bumpers nearly touching each other in a level parking lot. Both vehicles have their brakes off so that they are free to roll. A man sitting on the rear bumper of the truck exerts a constant horizontal force on the rear bumper of the car with his feet, and the car accelerates at 1.2 m/s^2. (*a*) What are the magnitude and direction of the acceleration of the center of mass of the car-truck system? (*b*) What vector sum of forces (magnitude and direction) is exerted on each vehicle? (*c*) What are the magnitude and direction of the acceleration of the truck? Ignore any friction between the tires and the parking lot surface. ••

78. A 70-kg skier is being towed on a rope behind a 450-kg snowmobile on a smooth, snow-covered surface at 10 m/s when the snowmobile hits a patch of muddy ground that brings it to a halt in 10 m. (*a*) What is the average acceleration of the snowmobile while it is slowing? (*b*) What is the average acceleration of the center of mass of the skier-snowmobile system? ••

79. A 4.0-kg block and a 2.0-kg block are connected to opposite ends of a relaxed spring of spring constant 300 N/m. The blocks are pushed toward each other for 0.50 s. The 4.0-kg block is pushed with a force of 50 N, and the 2.0-kg block is pushed with a force of 20 N. Ignore the inertia of the spring. (*a*) What is the acceleration of the center of mass of the two-block system while this pushing is going on? (*b*) When the blocks are released, what is the velocity of the 2.0-kg block if the 4.0-kg block is moving away from it at 5.0 m/s in the Earth reference frame? ••

8.12 Systems of many interacting objects

80. You push your 0.70-kg pillow across your bed with a constant force of 10 N. The bed provides a frictional force of 6.0 N. What is the acceleration of the center of mass of the pillow? •

81. You are holding a basketball while standing on a bathroom scale. You now throw the basketball directly upwards, and catch it on its way down. Describe how the reading on the scale changes from its initial value (*a*) as you are throwing the basketball, (*b*) after the basketball has left your hands, (*c*) while you are catching the basketball again. ••

82. You build a 2.0-kg mound of mashed potatoes on a kitchen scale (which is a spring scale). You then use a large spoon to press on the top of the mound at a constant force of 3.0 N. While you are doing this, the scale reading increases by 5.0%. (*a*) What is the acceleration of the center of mass of the potatoes? (*b*) Describe what happens to the shape of the mound and the scale reading as time goes by. ••

83. You use a rope of length ℓ to tie the front of a 1500-kg truck to the rear of a 1000-kg car and then use an identical rope of length ℓ to tie the front of the car to the rear of a 500-kg trailer. Each rope will break if its tension exceeds 2000 N. You attach a strong cable to the rear of the truck and use a winch to pull it with a force of magnitude F. (*a*) What is the acceleration of the three-vehicle system? (*b*) What is the maximum pulling force you can exert on the truck before a rope breaks? (*c*) If you now attach the cable to the front of the trailer and again pull the system, what is the maximum force with which you can pull it without snapping a rope? ••

84. A tugboat pulls two barges down the river. The barge connected to the tugboat, carrying coal, has an inertia of 2.0×10^5 kg, and the other barge, carrying pig iron, has an inertia of 3.0×10^5 kg. The resistive force between the coal barge and the water is 8.0×10^3 N, and the resistive force between the pig iron barge and the water is 10×10^3 N. The common acceleration of all three boats is 0.40 m/s^2. Even though the ropes are huge, the gravitational force exerted on them is much smaller than the pulling forces. (*a*) What is the tension in the rope that connects the tugboat to the coal barge? (*b*) What is the tension in the rope that connects the two barges? (*c*) Repeat parts *a* and *b* for the case in which the order of the barges is reversed. ••

85. A farmer is trying to haul three 500-kg trailers connected together with identical ropes that will break if their tension exceeds 2000 N. The first trailer is connected to his tractor with a rigid hitch. (*a*) If the tractor has to overcome a frictional force of 900 N per trailer to start them moving, what is the minimum force the tractor must exert on the first trailer to get them all rolling if the ropes are taut? (*b*) What is the maximum force the tractor can exert without breaking any rope? ••

86. A train is comprised of an engine car of inertia M, and 3 more cars of inertias m_1, m_2, and m_3, respectively. The acceleration of the train is *a*. Friction can be ignored. ••
   (*a*) What is the net force acting on the train?
   (*b*) What is the force in the coupler pulling the last car (m_3)?
   (c) What is the force in the coupler between the engine and the first car (m_1)?

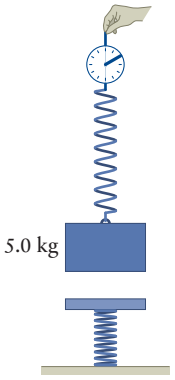
87. A red 10-kg cart is connected to a 20-kg cart by a relaxed spring of spring constant 60 N/m. The 20-kg cart is resting against another 10-kg cart, this one blue. All are on a low-friction track. You push the red 10-kg cart to the right, in the direction of the 20-kg cart, with a constant force of 10 N. (*a*) What is the acceleration of the center of mass of the three-cart system? (*b*) What is the acceleration of each cart the instant you begin to push? (*c*) What is the vector sum of the forces on each cart when the spring is compressed 100 mm? •••

Additional Problems

88. A toy wagon initially at rest is pulled by a child from one end of a driveway to the other end. The magnitude of the force the wagon exerts on the child is the same as the magnitude of the force the child exerts on the wagon. So, how does the child get the wagon moving? •

89. In years past, car frames were built as stiff as possible, but today's cars are built with "crumple zones" in the front and rear portions of the frame. What is the purpose of this design change? •

90. An 80-kg man rides in an elevator from the ground to an upper floor. The elevator goes from rest to 10 m/s in 5 seconds, and then continues at the same constant speed for 10 seconds, before slowing down to a stop in 5 seconds. How much push from the elevator floor does the man feel during (*a*) the initial acceleration, (*b*) the constant-speed phase, and (*c*) the final deceleration? ••



91. You want to hang an object from the ceiling of an elevator that has a maximum acceleration of 4.0 m/s^2. (*a*) If you hang the object with fishing line that supports 45 N of force, what is the maximum inertia the object can have if the line is not to break? (*b*) What combination of slowing down, speeding up, going up, and going down of the elevator causes the greatest force to be exerted on the fishing line? ••

92. You need to lower a 45-kg safe from a window to the bed of a 1800-kg truck. You have a rope that is just long enough, but it will support no more than 42 kg. What must you be careful to do (or not to do) so that the rope does not break? ••

93. A 10-kg cart is connected to a 20-kg cart by a relaxed spring of spring constant 1000 N/m, and both carts are placed on a low-friction track. You push the 10-kg cart in the direction of the 20-kg cart with a constant force of 10 N. (*a*) What is the acceleration of the center of mass of the two-cart system at any instant? (*b*) What is the acceleration of each cart at the instant you begin to push? (*c*) What is the acceleration of each cart when the spring has its maximum compression? ••

94. A 5.0-kg block suspended from a spring scale is slowly lowered onto a vertical spring (Figure P8.94). (*a*) What does the scale read before the block touches the vertical spring? (*b*) If the scale reads 40 N when the bottom spring is compressed 30 mm, what is *k* for the bottom spring? (*c*) How far does the block compress the bottom spring when the scale reads 0? ••

Figure P8.94

95. You need to lift a heavy load of inertia m_ℓ upward with an acceleration of magnitude $g/8$. You have two pulleys of inertia $m_P \ll m_\ell$, one attached to a beam above the loading dock and another that can be attached to the load. You consider a block-and-tackle system, which has two pulleys, but you realize that these are double pulleys (each has two wheels side by side on a common axle) and you have a long piece of rope. ••• CR

96. You and your uncle are fishing. You are using 22-N fishing line, which means the line can support that much tension without breaking. Your uncle challenges you to catch the biggest fish you can land in the boat with that line, with the provision that you have to hoist the fish

out of the water with the line and not with a net. You finally hook a fish that looks to have the right inertia, and you start to reel it in slowly. Just as you get the fish up into the air, though, the line snaps and the fish gets away. You accuse your uncle of having behind your back switched your pole to a line weaker than the 22-N line you thought you were working with, but he denies it. He then points out that you were accelerating the fish upward at 1.0 m/s^2. ●●● CR

97. Your 70-kg friend always thinks he can dominate you in contests of strength because, even though you are a very athletic gymnast, your inertia is 63 kg. This time, while the gym class watches, he has attached a pulley to the ceiling of the gym, passed a rope over it, and tied one end of the rope around his waist. He hands you the other end of the rope, which is not quite long enough to reach the floor, and bets you that you cannot lift him off the ground by pulling on the rope. You realize that gravitational forces will favor your friend if the two of you are hanging on opposite sides of the pulley, but then you recall your amazing arm strength gained from years of work on gymnastic apparatus. ●●● CR

98. A burst of compressed air pushes a pellet out of a blowpipe. The force exerted by the air on the pellet is given by $F(t) = F_0 e^{-t/\tau}$, where τ is called a *time constant* because it has units of time. (*a*) What does F_0 represent? (*b*) What is the momentum of the pellet after an interval equal to one time constant has elapsed? (*c*) What is the momentum after an interval equal to five time constants has elapsed? (*d*) What is the final momentum of the pellet after a long time interval has elapsed? (*e*) If $\tau = 0.50$ ms, after how long a time interval has the momentum reached 95% of its final value? ●●●

99. *Thrust* is the force that pushes a rocket forward. It is a force exerted on the rocket as the engine expels hot gases from the rear of the rocket. For most rockets, thrust is variable rather than constant during the "burn time" (the time interval during which fuel is consumed and expelled). However, the thrust of a certain rocket is nearly constant during part of its burn time, beginning when the rocket has consumed 40% of its fuel and continuing until the rocket has consumed about 90% of its fuel. As the rocket consumes and expels its fuel, its inertia decreases. Describe the rocket's acceleration during this interval of constant thrust. ●●●

Work

CONCEPTS

9.1 Force displacement
9.2 Positive and negative work
9.3 Energy diagrams
9.4 Choice of system

QUANTITATIVE TOOLS

9.5 Work done on a single particle
9.6 Work done on a many-particle system
9.7 Variable and distributed forces
9.8 Power

As you learned in Chapter 8, a system subject to external forces—that is to say, forces exerted by objects outside the system on objects inside the system—is not isolated. The relationship between the momentum of a nonisolated system and the vector sum of the forces exerted on that system is simple: The vector sum of the forces is equal to the time rate of change in the system's momentum (Eq. 8.4). In addition to affecting a system's momentum, external forces can change the energy of the system. In the simplest case, a single force exerted on a system consisting of a single object causes that object to accelerate, and so the force changes the object's kinetic energy. Forces can also change the physical state of objects (think of compressing or stretching a spring or crumpling a piece of paper by exerting a force on it). Because the physical state of an object is related to the object's internal energy, we see that forces can change not only an object's kinetic energy but its internal energy as well.

To describe these changes in energy, physicists use the concept of **work:**

Work is the change in the energy of a system due to external forces.

When an external force $\vec{F}_{\text{ext}}$ causes a change in the energy of a system, physicists refer to this change either as "the *work done by* the force $\vec{F}_{\text{ext}}$ on the system" or as "the *work done by* the object or person exerting force $\vec{F}_{\text{ext}}$ on the system."

Because work is a change in energy, the unit for work is the same as that for energy—the joule.

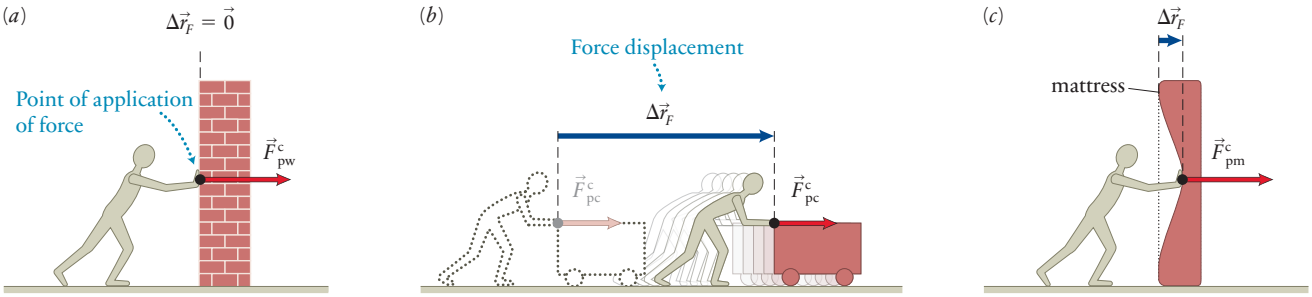
Note that this definition of work is much more limited than the meaning of the word *work* in ordinary language, which refers to any physical or mental effort or activity. You may be "doing work" for your physics class while reading this book, but there is no work involved in the physics sense.

9.1 Force displacement

Work amounts to a mechanical transfer of energy either from a system to its environment or from the environment to the system. For instance, if you (part of the "environment") push a friend on a bicycle (system is rider plus bicycle) and your friend accelerates, the force exerted by you on your friend transfers energy from your body to hers, increasing her kinetic energy. If you compress a spring, you transfer energy from your body to the spring, where it is stored in the form of elastic potential energy. In each case, the change in the system's energy is caused by an external force—a force exerted by you on the system.

If you wonder why a force has to be external to do work on a system—that is, to change the energy of the system—remember that forces represent interactions between objects. Any interaction between objects within the system rearranges the energy between these objects but doesn't change the overall amount of energy in the system. Only an interaction between an object inside the system and an object outside it—an external interaction—can transfer energy across the system boundary.

Do external forces *always* cause a change in the energy of a system? To answer this question, it is helpful to consider an example.



9.1 Imagine pushing against a brick wall as shown in Figure 9.1*a*. (Assume the wall is undeformable—a fair assumption at macroscopic scales.) (*a*) Considering the wall as the system, is the force you exert on it internal or external? (*b*) Does this force accelerate the wall? Change its shape? Raise its temperature? (*c*) Does the energy of the wall change as a result of the force you exert on it? (*d*) Does the force you exert on the wall do work on the wall?

As this checkpoint illustrates, external forces exerted on a system do not always do work on the system. The other two examples in **Figure 9.1**, however, do involve changes in energy, and hence in these cases work is done by your external force on the system. If, as shown in Figure 9.1*b*, you push against something that has wheels and so can accelerate it, its kinetic energy changes. If you push against a deformable object, the object changes shape and so its potential energy changes (Figure 9.1*c*).

Why is the work zero in Figure 9.1*a* but nonzero in parts *b* and *c*? The key to answering this question lies in looking at the *point of application* of each force (the point at which the force is exerted on the system, as indicated

CONCEPTS

Figure 9.1 An external force does work on a system only if it causes the point at which it is applied (represented by a black dot) to move.

Point of application does not move, so force does no work on wall.

Point of application moves, so force does work on cart.

Point of application moves, so force does work on mattress.

by the black dots in Figure 9.1). When you push against the brick wall, it neither moves nor deforms, and so the point of application of the force does not move. When you push the cart, you must move along with the cart to accelerate it; in other words, the point of application of the force is displaced. Similarly, when your force changes the shape of the deformable mattress in Figure 9.1*c*, the point of application of the force is displaced.

In order for a force to do work, the point of application of the force must undergo a displacement.

Whenever an external force is exerted on a system and the displacement of the point of application of the force is zero, no work is done by the force on the system. Conversely, in one dimension, when the **force displacement** (shorthand for "the displacement of the point of application of the force") is nonzero, the external force does work on the system, and so the energy of the system changes. (In more than one dimension, the angle between the force and the force displacement also plays a role. We shall discuss this point in Chapter 10.)* To distinguish the force displacement from other displacements, we add a subscript F to the symbol for displacement: $\Delta\vec{r}_F$.

EXERCISE 9.1 Displaced forces

For which of the following forces is the force displacement nonzero: (*a*) the force exerted by a hand compressing a spring, (*b*) the force exerted by Earth on a ball thrown upward, (*c*) the force exerted by the ground on you at the instant you jump upward, (*d*) the force exerted by the floor of an elevator on you as the elevator moves downward at constant speed?

SOLUTION (*a*), (*b*), and (*d*).

(*a*) The point of application of the force is at the hand, which moves to compress the spring.

(*b*) The point of application of the force of gravity exerted by Earth on the ball is at the ball, which moves.

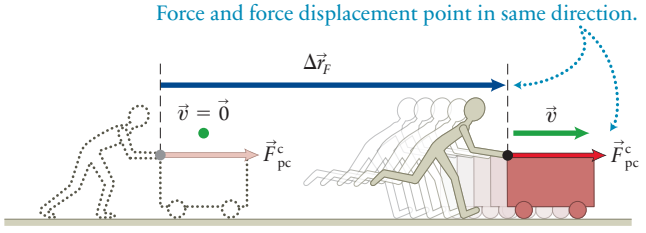
(*c*) The point of application is on the ground, which doesn't move (at a macroscopic scale).

(*d*) The point of application is on the floor of the elevator, which moves. ✔

9.2 You throw a ball straight up in the air. Which of the following forces do work on the ball while you throw it? Consider the interval from the instant the ball is at rest in your hand to the instant it leaves your hand at speed v. (*a*) The force of gravity exerted by Earth on the ball. (*b*) The contact force exerted by your hand on the ball.

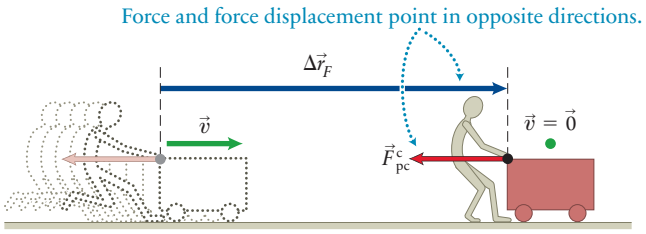
*Two additional external forces are exerted on the cart in Figure 9.1*b* that have nonzero force displacements: the force of gravity and the contact force exerted by the ground. However, these two forces are equal in magnitude and opposite in direction and so they "cancel out": Their net effect is the same as that of no force. Therefore no work is done by these forces on the cart.

9.2 Positive and negative work



When the energy of a system increases as a result of an external force exerted on the system, the change in energy is positive, and so the work done by that external force on the system is said to be positive. An external force can also decrease the energy of a system, however. For instance, imagine slowing down a friend who is coasting on a bicycle. In this case, the kinetic energy of the system decreases, the change in energy is negative, and so the work done by the external force (that is, by you on your friend) on the system is said to be negative.

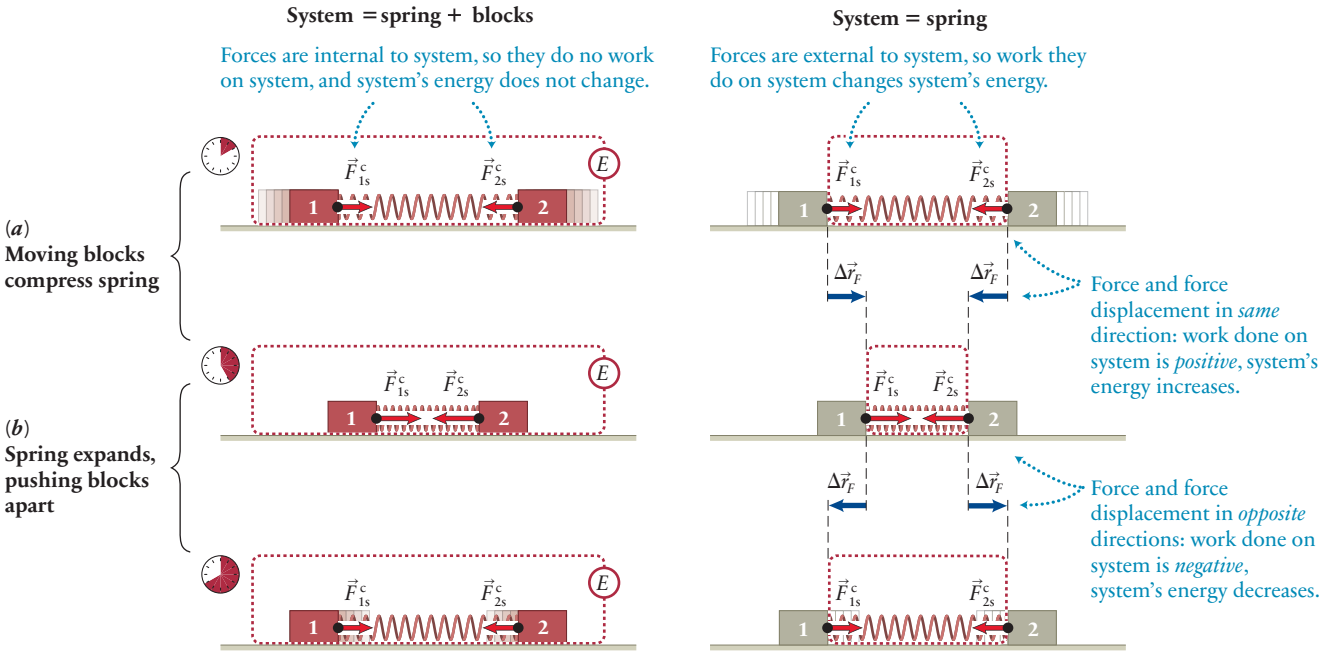
9.3 A ball is thrown vertically upward. (*a*) As it moves upward, it slows down under the influence of gravity. Considering the changes in energy of the ball, is the work done by Earth on the ball positive or negative? (*b*) After reaching its highest position, the ball moves downward, gaining speed. Is the work done by the gravitational force exerted on the ball during this motion positive or negative?



Examples of positive and negative work are illustrated in **Figure 9.2**. In both cases the person exerts a force $\vec{F}^{c}_{pc}$ on the cart. What, then, is the difference between these two situations? The difference lies in the direction in which the force is applied. To speed the cart up, the person must push in the direction of travel of the cart; the force vector $\vec{F}^{c}_{pc}$ and the force displacement $\Delta\vec{r}_F$ point in the same direction. To slow the cart down, the force must be applied in the direction opposite the cart's direction of travel; the force $\vec{F}^{c}_{pc}$ and the force displacement $\Delta\vec{r}_F$ point in opposite directions.

Figure 9.2 The work done on a system is positive if the system gains kinetic energy and negative if the system loses kinetic energy.

(*a*) Cart speeds up, so positive work is done on it



(*b*) Cart slows down, so negative work is done on it

CONCEPTS

Figure 9.3 Only forces that are *external* to a system can do work on the system and change the system's energy.

The work done by a force on a system is positive when the force and the force displacement point in the same direction and negative when they point in opposite directions.

9.4 Go back to Checkpoint 9.3 and answer the same two questions in terms of the directions of the applied forces and the force displacements. Do your answers agree with those you gave in Checkpoint 9.3?

Let us next consider a situation involving changes in potential energy. Figure 9.3*a* shows a spring being compressed by two moving blocks. There are two ways to look at this problem. We can consider the spring and the blocks as a closed system whose energy must remain constant, or we can consider just the spring as a system on which the blocks do work.

For the closed blocks-spring system in Figure 9.3*a*, the potential energy of the spring increases during the compression by an amount equal to the decrease in the blocks' kinetic energy. Because no external forces are exerted on the system, no work is involved.

Considering just the spring as our system in Figure 9.3*a*, we note that the increase in the spring's potential energy results from the work done by the blocks on it. Because the spring's potential energy increases, the work done on the system must be positive. Indeed, the forces exerted by the blocks on the spring point in the same direction as the force displacements.

Figure 9.3*b* shows the reverse situation: Two blocks are held against a compressed spring and then released, so that they accelerate away from each other. For the closed blocks-spring system, the energy doesn't change, and we can account for the increase in kinetic energy of the blocks by a decrease in the potential energy of the expanding spring. If, however, we consider the spring by itself as our system, the decrease in energy of the system implies that the work done by the blocks on the spring is negative.

Let us see if we reach the same conclusion for the sign of the work in Figure 9.3*b* when we look at the directions of the forces and the force displacements. Because we are interested in the work done *on the spring*, we need to consider the forces exerted by the blocks on it. These forces still point toward the spring, as shown in Figure 9.3*b*.* The force displacements, however, now point in the opposite direction, away from the spring. Because each force and its force displacement point in opposite directions, the work done by the blocks on the spring is negative. Everything is consistent: Both energy considerations and the directions of the forces and force displacements tell us that the work done by the blocks on the spring is negative as the spring expands.

CONCEPTS

*Careful! You may think the spring exerts a force on the blocks and not the other way around. Don't forget, however, that the force exerted by the spring on each block is just one part of an interaction pair. If you are having trouble picturing the force exerted by the blocks on the spring, imagine the spring expanding without having to push against the blocks: The expansion would be easier because there would be no resistance from the blocks. So, in a sense, the force exerted by the blocks on the spring slows down the expansion of the spring.

EXERCISE 9.2 Positive and negative work

Is the work done by the following forces considered in Exercise 9.1 positive, negative, or zero? In each case the system is the object on which the force is exerted. (*a*) The force exerted by a hand compressing a spring, (*b*) the force exerted by Earth on a ball thrown upward, (*c*) the force exerted by the ground on you at the instant you jump upward, (*d*) the force exerted by the floor of an elevator on you as the elevator moves downward at constant speed.

SOLUTION (*a*) Positive. To compress a spring, I must move my hand in the same direction as I push. ✔

(*b*) Negative. The force exerted by Earth points downward; the point of application moves upward. ✔

(*c*) Zero, because the point of application is on the ground, which doesn't move. ✔

(*d*) Negative. The force exerted by the elevator floor points upward; the point of application moves downward. ✔

9.5 Suppose that instead of the two moving blocks in Figure 9.3*a*, just one block is used to compress the spring while the other end of the spring is held against a wall. (*a*) Is the system comprising the block and the spring closed? (*b*) When the system is defined as being only the spring, is the work done by the block on the spring positive, negative, or zero? How can you tell? (*c*) Is the work done by the wall on the spring positive, negative, or zero?

9.3 Energy diagrams

In analyzing situations involving work, we extend the bar diagrams introduced in Chapter 5 to include work done on the system. Consider, for example, the situation in **Figure 9.4*a***. The energy of the system represented by this diagram increases from 10 J to 15 J. In order for this 5-J increase to occur, an amount of work equal to 5 J must be done by external forces on the system. The length of the vertical bar representing the final energy is equal to the sum of the lengths of the bars representing the initial energy and the work done by the external forces on the system.

Figure 9.4 Bar diagrams showing the work done on a system. Positive work adds to the system's energy; negative work subtracts from it.

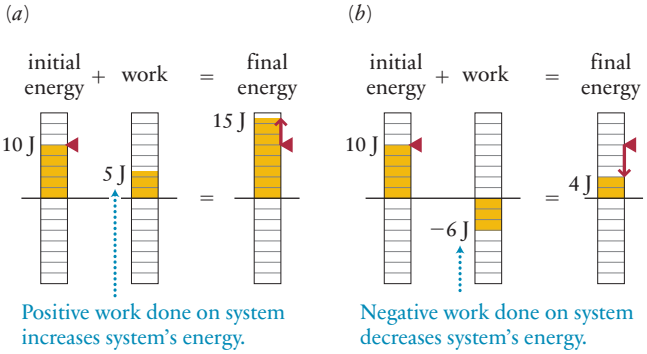


Figure 9.4*b* represents a system whose energy decreases. In order for the energy to decrease, the work done by external forces on the system must be negative, and so the bar representing this work extends below the baseline.

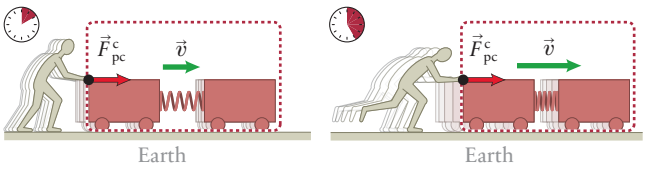
Because any of the four kinds of energy discussed in Chapter 7 (kinetic energy K, potential energy U, source energy E_s, and thermal energy E_{th}) can change in situations involving work, our bar diagrams need to include more detail in order to show in what form the energy transferred to a system appears when some external force does work on it. The additional bars make these diagrams more cumbersome to draw, however, and therefore we introduce the following simplification. Instead of drawing one set of bars for each of the initial and final individual energies, we draw just one set of bars representing the *change* in each category of energy, and we add a fifth bar, denoted by W, representing the work done by external forces on the system. We call these diagrams **energy diagrams.** Energy diagrams are a graphic representation of conservation of energy: They show that the energy of a system can change only due to the transfer of energy into or out of the system.

Just as with free-body diagrams, the first step in drawing an energy diagram is to define the system. In addition we should show any external force whose point of application undergoes a nonzero displacement; these are the forces that do work on the system. Consider, for example, the situation shown in **Figure 9.5*a***: a person pushing a pair of carts connected by a spring. The pushing accelerates the carts and compresses the spring. Let us choose a system comprising the pair of carts and the spring; Figure 9.5*a* shows its initial and final states. We also draw a vector representing the external force $\vec{F}^{c}_{pc}$ exerted by the person on the left cart and indicate the position of the point of application of that force with a black dot.

Because the carts speed up, the final kinetic energy of the system is greater than the initial kinetic energy and the change in kinetic energy $\Delta K = K_f - K_i$ is therefore positive. This change in kinetic energy corresponds to the upward-pointing arrow marked ΔK in Figure 9.5*b*, which is a set of the bar diagrams we used before now (no work values are shown). The compression of the spring causes the elastic potential energy stored in the spring to increase, and so the change in potential energy $\Delta U = U_f - U_i$ is also positive, as shown by the upward-pointing arrow in Figure 9.5*b*.

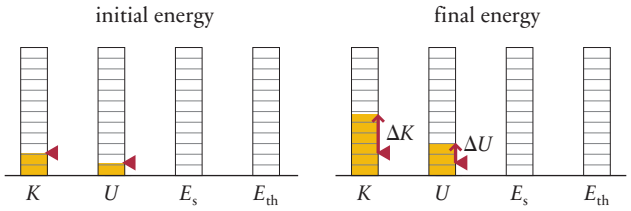
To represent this same information in an energy diagram (Figure 9.5*c*), we draw bars to represent the changes ΔK and ΔU. The heights of the bars, which are equal to the heights of the arrows in Figure 9.5*b*, now represent the *changes* in each energy category. The ΔE_s and ΔE_{th} bars are empty because there are no changes in these energies.



The change in the system's energy comes from the work done by external forces on the system. The length of the bar representing the work done on the system in Figure 9.5*c* must therefore equal the sum of the lengths of the ΔK and ΔU bars. Note that these energy arguments

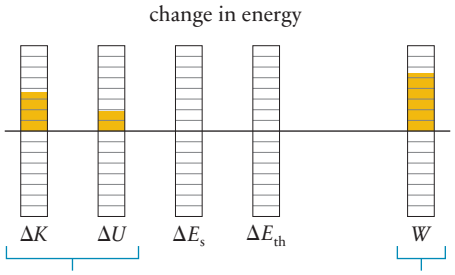
CONCEPTS

Figure 9.5 (*a*) Changes in a system's energy can be shown (*b*) by initial and final bar diagrams or, more compactly, (*c*) by a single energy diagram, which shows the *changes* in energy in each category and a column showing work done on the system.



(*a*)

External work by person changes system's kinetic and potential energy.

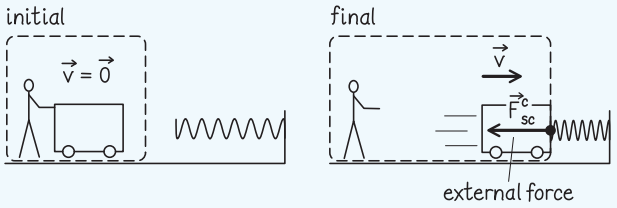


(*b*)

We can represent the changes in energy by initial and final bar diagrams . . .

(*c*) . . . or by a single **energy diagram**.

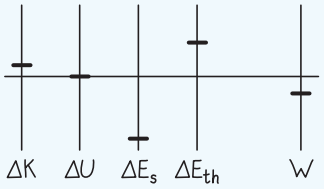
tell us that the work done by external forces on the system must be positive. We can verify this sign by checking the directions of the force exerted on the system and its force displacement. From Figure 9.5*a*, we see that both are to the right, and so the work done by external forces on the system is indeed positive.



The general procedure for making energy diagrams is summarized in the Procedure box "Drawing Energy Diagrams"on page 288.

EXERCISE 9.3 Cart launch

A cart is at rest on a low-friction track. A person gives the cart a shove and, after moving down the track, the cart hits a spring, which slows down the cart as the spring compresses. Draw an energy diagram for the system that comprises the person and the cart over the time interval from the instant the cart is at rest until it has begun to slow down.



SOLUTION Following the steps in the Procedure box, I begin by listing the objects that make up the system: cart and person. Then I sketch the system in its initial and final states (**Figure 9.6**). The external forces exerted on the system are the force of gravity on person and cart, the contact force exerted by ground on person, the contact force exerted by track on cart, and the contact force exerted by spring on cart. The vertical forces add up to zero, and so the work done by them on the system is zero. The force exerted by the spring on the cart, however, undergoes a force displacement, so I include that force in my diagram and indicate its point of application, as shown in Figure 9.6.

Figure 9.6

Next I determine whether there are any changes in energy. Kinetic energy: The cart begins at rest and ends with nonzero speed, which means a gain in kinetic energy (**Figure 9.7**). Potential energy: Neither the configuration of the cart nor that of the person changes in a reversible way, so the potential energy does not change. (The configuration of the spring does change in a reversible way, but the spring is not part of the system.) Source energy: The person has to exert effort to give the cart a shove, so source energy is consumed. The source energy of the system therefore decreases. Thermal energy: No friction is involved, but the conversion of source energy is always accompanied by the generation of thermal energy, so the thermal energy increases. (The person's muscles heat up.)

Figure 9.7

In Figure 9.6 the force exerted by the spring on the cart points to the left and the force displacement points to the right. This means that the work done by the spring on the cart is negative, and the *W* bar of my energy diagram must extend below the baseline. I adjust the lengths of the bars so that the length of the *W* bar is equal to the sum of the lengths of the other bars, yielding the energy diagram shown in Figure 9.7. ✔

9.6 Draw an energy diagram for the cart in Figure 9.2*b*.

CONCEPTS

PROCEDURE: Drawing energy diagrams

1. Specify the **system** under consideration by listing the components inside the system.
2. **Sketch** the system in its initial and final states. (The initial and final states may be defined for you by the problem, or you may have to choose the most helpful states to examine.) Include in your sketch any external forces exerted on the system that undergo a nonzero force displacement, and draw a dot at the point of application of each force.
3. Determine any nonzero **changes in energy** for each of the four categories of energy, taking into account the four basic energy-conversion processes illustrated in Figure 7.13:
   - **a.** Did the speed of any components of the system change? If so, determine whether the system's kinetic energy increased or decreased and draw a bar representing ΔK for the system. For positive ΔK, the bar extends above the baseline; for negative ΔK, it extends below the baseline. (For some problems you may wish to draw separate ΔK bars for different objects in the system; if so, be sure to specify clearly the system component that corresponds to each bar and verify that the entire system is represented by the sum of the components.)
   - **b.** Did the configuration of the system change in a reversible way? If so, draw a bar representing the change in potential energy ΔU for the system. If necessary, draw separate bars for the changes in different types of potential energy, such as changes in elastic and gravitational potential energy.
   - **c.** Was any source energy consumed? If so, draw a bar showing ΔE_s. Source energy usually decreases, making ΔE_s negative, and so the bar extends below the baseline. Keep in mind that conversion of source energy is always accompanied by generation of thermal energy (Figure 7.13*c* and *d*).
   - **d.** Does friction occur within the system, or is any source energy consumed? If so, draw a bar showing ΔE_{th}. In nearly all cases we consider, the amount of thermal energy increases, and so ΔE_{th} is positive.
4. Determine whether or not any **work** W is done by external forces on the system. Determine whether this work is negative or positive. Draw a bar representing this work, making the length of the bar equal to the sum of the lengths of the other bars in the diagram.

   If no work is done by external forces on the system, leave the bar for work blank, then go back and adjust the lengths of the other bars so that their sum is zero.

CONCEPTS

EXERCISE 9.4 Compressing a spring

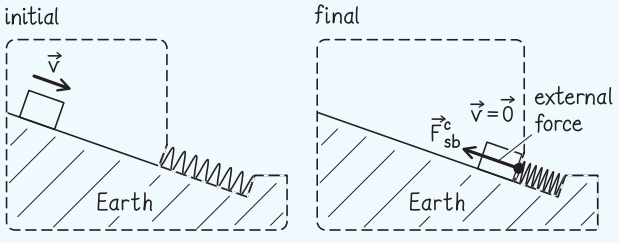
A block initially at rest is released on an inclined surface. The block slides down, compressing a spring at the bottom of the incline; there is friction between the surface and the block. Consider the time interval from a little after the release, when the block is moving at some initial speed v, until it comes to rest against the spring. Draw an energy diagram for the system that comprises the block, surface, and Earth.

SOLUTION I begin by listing the objects that make up the system: block, surface, and Earth. Then I sketch the initial and final states of the system (**Figure 9.8**). The spring exerts external forces on the system. The bottom end of the spring exerts a force on the surface edge, but this force has a force displacement of zero. The top end of the spring exerts a force $\vec{F}^{c}_{sb}$ on the block. Because this force undergoes a nonzero force displacement, I include it in my diagram and show a dot at its point of application.

Next I determine whether there are any energy changes. Kinetic energy: The block's kinetic energy goes to zero, and the kinetic energies of the surface and Earth do not change. Thus the kinetic energy of the system decreases, and ΔK is negative. Potential energy: As the block moves downward, the gravitational potential energy of the block-Earth system decreases, and so ΔU is negative. (Because the spring gets compressed, its elastic potential energy changes, but the spring is not part of the system.) Source energy: none (no fuel, food, or other source of energy is converted in this problem). Thermal energy: As the block slides, energy is dissipated by the friction between the surface and the block, so ΔE_{th} is positive.

To determine the work done on the system, I look at the external forces exerted on it. The point of application of the external force $\vec{F}^{c}_{sb}$ exerted by the spring on the block undergoes a force displacement opposite the direction of the force, so that force does negative work on the system. Thus the work done on the system by the external forces is negative, and the W bar extends below the baseline (**Figure 9.9**). I adjust the lengths of the bars so that the length of the W bar is equal to the sum of the lengths of the other three bars, yielding the energy diagram shown in Figure 9.9. ✔

Figure 9.8



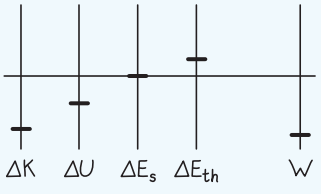


Figure 9.9

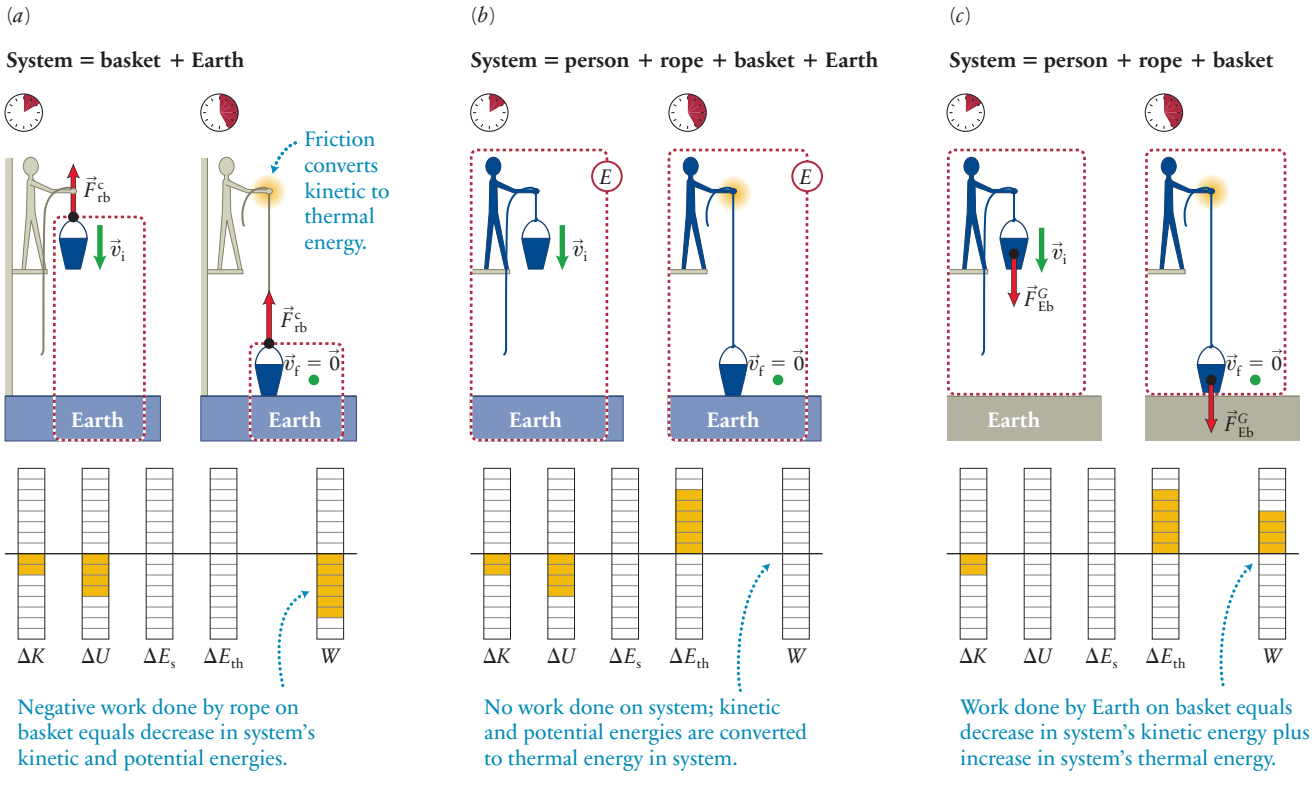
9.7 Draw an energy diagram for the situation presented in Exercise 9.4, but choose the system that comprises block, spring, surface, and Earth.

9.4 Choice of system

For a given situation, different choices of system yield different energy diagrams, as you just saw if you did Checkpoint 9.7. To examine this point further, consider the situation shown in **Figure 9.10**. Using a long rope, a person lowers a basket from a balcony, smoothly putting the basket down on the ground. The basket initially moves downward at speed v_i, but friction between the person's hands and the rope slows the basket so that it ends up at rest on the ground. For simplicity we assume no source energy is consumed; the person just lets the rope slide, exerting no physical effort.

Let us begin by choosing the basket and Earth as our system, a choice that leads to the energy diagram shown in Figure 9.10*a*. Because the basket comes to rest, its kinetic energy decreases. As the distance between Earth and basket decreases, the potential energy of the Earth-basket system decreases. There is no conversion of source energy nor any dissipation of energy within the system, and so we leave the columns for ΔE_s and ΔE_{th} blank.



Next we examine the external forces exerted on the system. The person exerts forces both on Earth and, via the rope, on the basket. The latter involves a nonzero force displacement (the knot, which is the point of application for the force exerted by the rope on the basket, moves downward), so work is done on the system. This work is negative because the force exerted by the rope on the basket is upward and the force displacement is downward. In order to make the work equal to the change in the system's energy, the length of the bar representing work must be made equal to the sum of the lengths of the ΔK and ΔU bars.

What this energy diagram tells us is that the energy of the basket-Earth system decreases as energy is transferred out of the system. Because energy is transferred out of the system, the work done by the person on the system is negative.

What happens if we include the person and the rope in the system, as is Figure 9.10*b*? The changes in the kinetic and potential energies are the same as before, but now the person no longer exerts external forces and therefore cannot do any work on the system. In fact, because we have included everything in the system, there are no external forces and so there is no work done by external forces on the system—the system is closed.

For this choice of system, we have to take into account the dissipation of energy because of friction between the person's hands and the rope, and so we have a positive ΔE_{th}. The resulting energy diagram tells us that the initial kinetic energy of the basket and

Figure 9.10 Different choices of system yield different energy diagrams.

CONCEPTS

the initial potential energy of the system are converted to thermal energy (the rope and the person's hands heat up). No work is done by external forces on the system because the system is closed. This conclusion is entirely consistent with the one we drew on the basis of Figure 9.10*a*, but in the process we've obtained more information on where the energy went.

Finally we consider the same situation for a system that comprises only basket, person, and rope, as in Figure 9.10*c*. The changes in the kinetic and thermal energies are as before. For this choice of system, however, there is no change in gravitational potential energy (remember that gravitational potential energy refers to the configuration of Earth and the basket *together*, and Earth is no longer part of the system). What was counted as gravitational potential energy in Figure 9.10*a* and *b* appears as work done by the gravitational force on the system here. Earth exerts a downward external force on the basket as the basket moves downward, so Earth does positive work on the basket. (Earth also exerts a downward force on the person, but this force involves no force displacement.)

In Section 9.5, I shall show that the positive work done by the gravitational force on the system in Figure 9.10*c* is exactly equal to the negative of the change in the gravitational potential energy in Figures 9.10*a* and *b*. As this example shows, in order to avoid double-counting, it is important always to remember the following point:

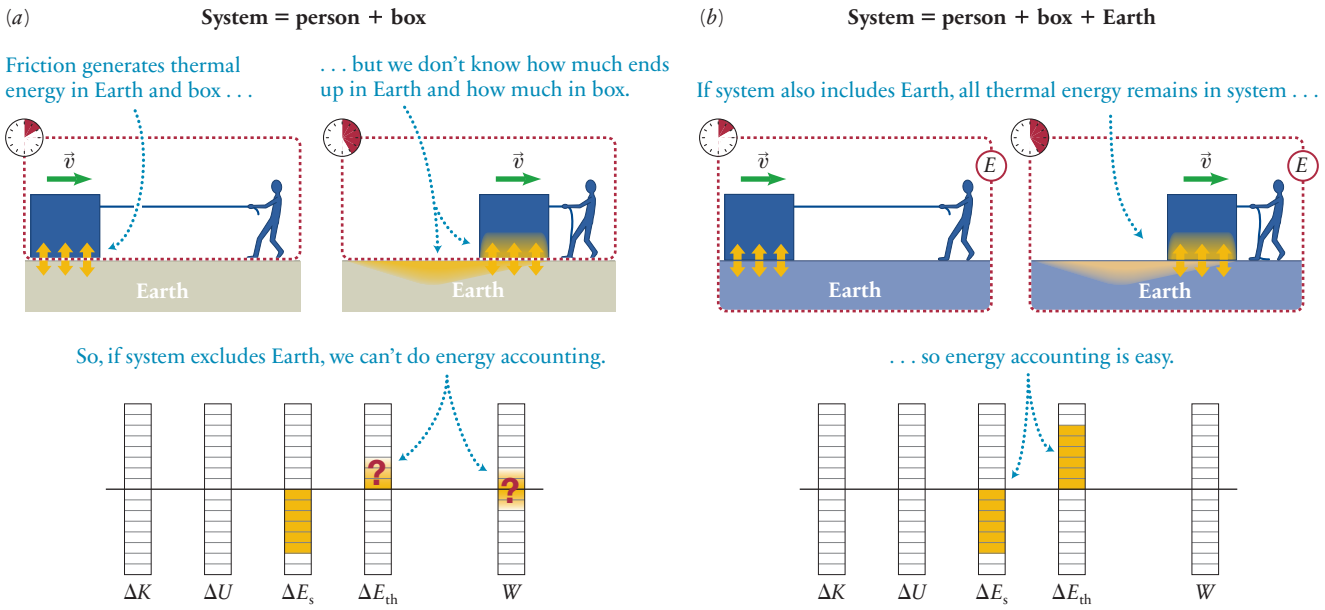
Gravitational potential energy always refers to the relative position of various parts within a system, never to the relative positions of one component of the system and its environment.

Whenever you are looking at the energy associated with the gravitational interaction between an object inside your system and an object outside the system, do not include that energy in the ΔU bar of your energy diagram. That energy must be accounted for in the W part of the diagram instead.

The energy diagram of Figure 9.10*c* shows how the initial kinetic energy of the basket and the positive work done by Earth on the system end up as thermal energy.

All three choices of system lead to a valid conclusion. By looking at a situation from various points of view, you gain a better understanding of what energy conversions and transfers take place. Also, by looking at a situation in various ways and verifying that your answers are consistent with one another, you can convince yourself that you have not overlooked something.

9.8 Draw an energy diagram for just the basket in Figure 9.10.



Although you are generally free to choose whichever system suits you best, there are certain choices of system that lead to complications. In particular:

When drawing an energy diagram, do not choose a system for which friction occurs at the boundary of the system.

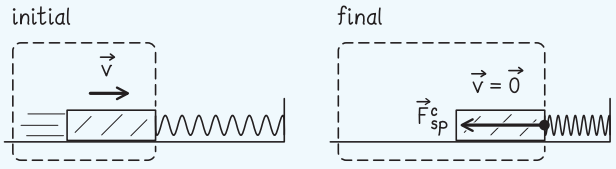
The reason for this is simple: Wherever friction occurs, thermal energy is generated. The problem is that this thermal energy appears on both sides of the surface where friction occurs. If you pull on a rope to draw a large box toward yourself, as in **Figure 9.11**, friction between floor and box heats up both box and floor.

CONCEPTS

Figure 9.11 If you need to do energy accounting, don't choose a system for which friction occurs at the system boundary.

The thermal energy generated ends up partly in the floor and partly in the box. How much ends up where depends, among other things, on the materials that rub against each other and is not something that can be determined easily. So, if you choose just the box as your system, an unknown amount of energy flows out of the system, and it is no longer possible to do the energy accounting for the system.

There is another reason friction at a system boundary leads to problems. Whenever friction occurs at a boundary, the frictional force is *external* to the system (it is exerted by the environment on the system) and hence has to be taken into account in the computation of the work done on the system. The force of friction, however, is not applied at a single, well-defined location. Instead, it is distributed over the surfaces that move relative to each other. Consequently it is not possible to determine the force displacement, which is the other piece of information necessary to determine the work done on the system.



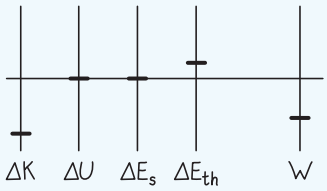
These problems with friction at a system boundary don't mean we can never treat any situations involving friction. Both our analyses of Figure 9.10 and Exercise 9.4 involve friction, but for all choices of system we considered, the two objects that rub against each other were kept together either inside or outside the system.

EXAMPLE 9.5 Puck and spring

A puck sliding on a horizontal surface hits the free end of a spring that is held fixed at the other end. There is friction between puck and surface. Consider the interval from the instant before the puck comes in contact with the spring until the instant the puck has zero velocity and the spring reaches maximum compression. Draw an energy diagram for a system that contains the puck and for which the work done on the system is nonzero. (Your system may include objects in addition to the puck if you like.)

1 GETTING STARTED I begin by making situation sketches at the beginning and end of the time interval of interest. The items in my sketches are the puck, the surface, and the spring (**Figure 9.12**).

Figure 9.12



If I include all three items in my system, the system is closed, so the work done by external forces on the system is zero. Because there is friction between surface and puck, I must keep the two together. Given that the puck must be part of the system, I have no choice but to have my system be the puck plus the surface, so I draw my system boundary around these two objects. The only external force exerted on this system is the contact force exerted by the spring on the puck, so I add that force to my diagram and indicate its point of application.

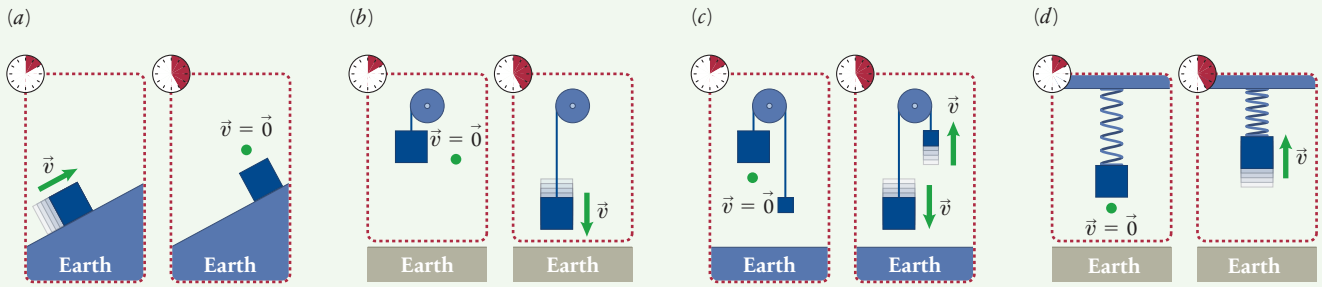
2 DEVISE PLAN All I have to do is follow the procedure for drawing an energy diagram for my system.

3 EXECUTE PLAN My energy diagram is shown in **Figure 9.13**. Because the puck slows to a stop, its kinetic energy decreases. Because there are no reversible changes in the system configuration and because no source energy is consumed, my bars for ΔU and ΔE_s must be zero. The friction causes dissipation of energy, so the ΔE_{th} bar shows an increase.

Figure 9.13

Because the external force exerted by the spring on the system points in the direction opposite the direction of the force displacement, the work done by the spring on the system is negative. I adjust the lengths of the bars so that the length of the W bar is equal to the sum of the lengths of the other bars. ✔

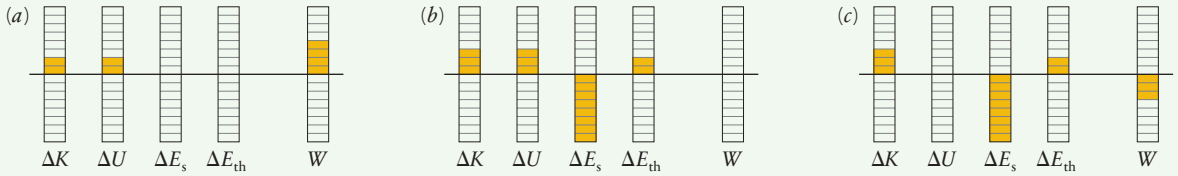
4 EVALUATE RESULT The puck slows down under the combined action of the frictional force and the force exerted by the spring. So part of the puck's initial kinetic energy is converted to thermal energy, and the rest goes into compressing the spring. Because the spring is not part of the system, that energy leaves the system as (negative) work.



9.9 (*a*) Draw an energy diagram for the situation shown in Figure 9.11 for the system that comprises Earth and the box. Assume the box keeps moving at constant velocity, and consider the rope to be part of the person. (*b*) Explain each bar in the energy diagram of Figure 9.11*b*.

CONCEPTS

Self-quiz



1. A stunt performer falls from the roof of a two-story building onto a mattress on the ground. The mattress compresses, bringing the performer to rest without his getting hurt. Is the work done by the mattress on the performer positive, negative, or zero? Is the work done by the performer on the mattress positive, negative, or zero?
2. Consider a weightlifter holding a barbell motionless above his head. (*a*) Is the sum of the forces exerted on the barbell zero? (*b*) Is the weightlifter exerting a force on the barbell? (*c*) If the weightlifter exerts a force, does this force do any work on the barbell? (*d*) Does the energy of the barbell change? (*e*) Are your answers to parts *c* and *d* consistent in light of the relationship between work and energy?
3. Do any of the systems in **Figure 9.14** undergo a change in potential energy? If yes, is the change positive or negative? Ignore any friction.

Figure 9.14

4. A person pushes a cart up a small hill, gaining speed along the way. Friction in the cart's wheels is negligible. Name the components of the system depicted in each energy diagram shown in **Figure 9.15**.

Figure 9.15

Answers

1. Because the mattress brings the performer to rest, $\vec{F}^{c}_{mp}$ must point upward. The point of application of this force moves downward as the mattress compresses, meaning the work done by the mattress on the performer is negative. The work done by the performer on the mattress is positive because $\vec{F}^{c}_{pm}$ points downward and its point of application moves downward.
2. (*a*) Yes, because the barbell remains motionless. (*b*) Yes. He exerts an upward force to counter the downward gravitational force. (*c*) No, because the point at which the lifter exerts a force on the barbell is not displaced. (*d*) No. (*e*) They are consistent. If no work is done on a system, the energy of the system does not change.
3. Yes. (*a*), (*c*), and (*d*). Because none of the situations involves friction or the conversion of source energy, the only things you need to consider are changes in the kinetic and potential energies and work done by external forces on the system. The system in part *a* is closed, and so the decrease in kinetic energy causes an increase in gravitational potential energy: $\Delta U > 0$. In part *b*, Earth is not included in the system, so there can be no potential energy component of the system's energy. In part *c*, the system is closed, so the increase in kinetic energy must be due to a decrease in gravitational potential energy: $\Delta U < 0$. In part *d*, Earth does negative work on the system, so the energy of the system must decrease. Because the kinetic energy increases, the elastic potential energy of the spring must decrease: $\Delta U < 0$.
4. If there is a change in potential energy, the cart and Earth must be in the system; if there is a change in source energy, the person must be in the system. (*a*) Cart and Earth. The person does positive work on the system. (*b*) Person, cart, and Earth. This system is closed; no work is done by external forces on it. Source energy is converted to increase the kinetic and potential energies (and some of it is dissipated). There is more kinetic and potential energy in this system than in part *a* because the person is included in the system. (*c*) Person and cart. Earth does negative work on the system.

9.5 Work done on a single particle

In the first part of this chapter we defined work as the change in the energy of a system due to external forces, and we represented work by the letter W. The SI unit of work is the same as that of energy, J. When work is done by external forces on a system, the energy of the system changes by an amount

$$\Delta E = W. \tag{9.1}$$

This equation is called the **energy law** and embodies conservation of energy: Because energy cannot be created or destroyed, the energy of a system can change only if energy is transferred into or out of the system.* For a system that is closed, $W = 0$ and so the energy law takes on the form we encountered in Chapter 5: $\Delta E = 0$.

To calculate the work done by an external force on a system, we start by considering a simple case: a single particle of inertia m subject to a constant force $\vec{F}$. The term **particle** refers to any object that has no internal structure and no extent in space. Because it lacks extent and internal structure, a particle cannot change shape and therefore any internal energy is fixed ($\Delta E_{\text{int}} = 0$). Only the kinetic energy of a particle can change, so

$$\Delta E = \Delta K \quad \text{(particle)}. \tag{9.2}$$

To calculate what happens to the kinetic energy of a particle subject to a constant force $\vec{F}$, we consider the particle's motion over a time interval $\Delta t = t_{\text{f}} - t_{\text{i}}$ for the case where the particle's velocity at instant t_{i} is $\vec{v}_{\text{i}}$. The constant force gives the particle a constant acceleration given by the equation of motion (Eq. 8.8):

$$a_x = \frac{\Sigma F_x}{m} = \frac{F_x}{m}. \tag{9.3}$$

At the end of the time interval, the x component of the particle's velocity is given by Eq. 3.4,

$$v_{x,\text{f}} = v_{x,\text{i}} + a_x \Delta t, \tag{9.4}$$

and the x component of the particle's displacement is given by Eq. 3.7,

$$\Delta x = v_{x,\text{i}} \Delta t + \tfrac{1}{2} a_x (\Delta t)^2. \tag{9.5}$$

Because we are considering a particle, the displacement of the particle is also the force displacement.

Using these expressions, we can evaluate the change in the particle's kinetic energy:

$$\Delta K = K_{\text{f}} - K_{\text{i}} = \tfrac{1}{2} m (v_{\text{f}}^2 - v_{\text{i}}^2). \tag{9.6}$$

*For now, we consider only mechanical transfers of energy and ignore any other type of energy transfer. Later we'll also take into account transfer of energy by heating and radiation.

Substituting Eq. 9.4 into Eq. 9.6 and keeping in mind that $v^2 = v_x^2$ and $a^2 = a_x^2$, we get

$$\begin{aligned}\Delta K &= \tfrac{1}{2}m[(v_{x,\mathrm{i}} + a_x\Delta t)^2 - v_{x,\mathrm{i}}^2] \\ &= \tfrac{1}{2}m[2v_{x,\mathrm{i}}a_x\Delta t + a_x^2(\Delta t)^2] \\ &= ma_x\left[v_{x,\mathrm{i}}\Delta t + \tfrac{1}{2}a_x(\Delta t)^2\right] \\ &= ma_x\Delta x_F = F_x\Delta x_F, \end{aligned} \tag{9.7}$$

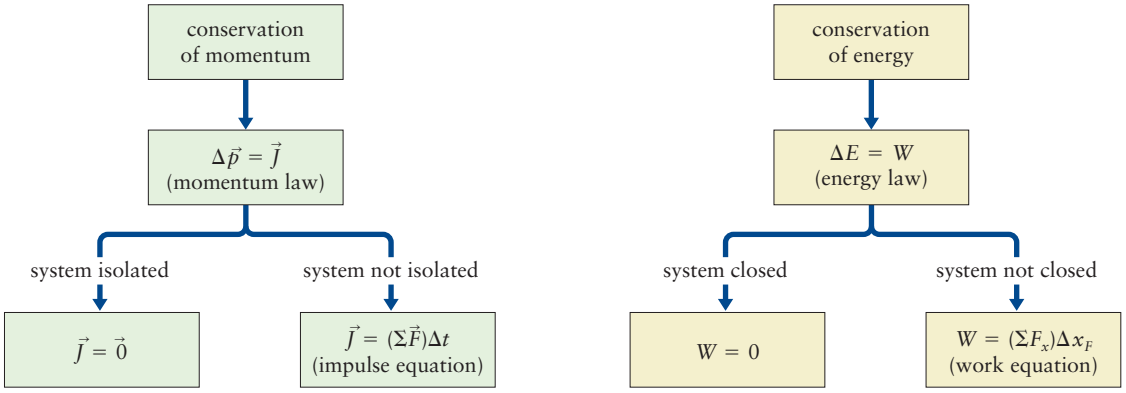
where the substitution $v_{x,\mathrm{i}}\Delta t + \frac{1}{2}a_x(\Delta t)^2 = \Delta x_F$ comes from Eq. 9.5, the substitution $ma_x = F_x$ comes from Eq. 9.3, and Δx_F carries a subscript F to remind us that this is the **force displacement** (the displacement of the point of application of the force). Having found this result $\Delta K = F_x\Delta x_F$, we can use Eq. 9.2, $\Delta E = \Delta K$, to say that $\Delta E = F_x\Delta x_F$ and then Eq. 9.1, $\Delta E = W$, to finally say

$$W = F_x\Delta x_F \quad \text{(constant force exerted on particle, one dimension).} \tag{9.8}$$

In words:

For motion in one dimension, the work done by a constant force exerted on a particle equals the product of the x components of the force and the force displacement.

If the external force $\vec{F}$ and the force displacement $\Delta\vec{r}_F$ point in the same direction, F_x and Δx_F are either both positive or both negative, and so the product $F_x\,\Delta x_F$ is positive. Consequently, the kinetic energy increases. When the force and the particle's displacement point in opposite directions, F_x and Δx_F have opposite algebraic signs. The work done by the force on the particle is then negative, and so the kinetic energy of the particle decreases.



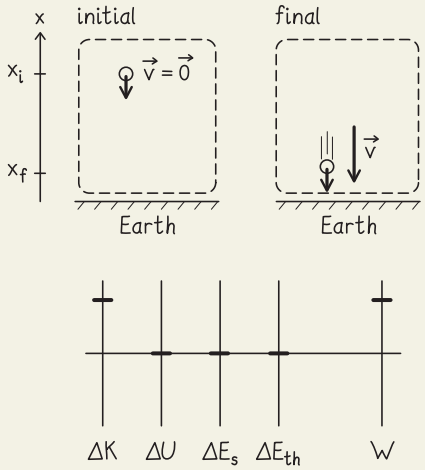
If more than one force is exerted on a particle, the x component of its acceleration is given by Eq. 8.8: $a_x = \sum F_x/m$. Substituting this expression for the x component of the acceleration into Eq. 9.7 gives $\Delta K = (\sum F_x)\Delta x_F$. Moving on to Eq. 9.8, we obtain the work done by these forces on the particle:

$$W = (\textstyle\sum F_x)\Delta x_F \quad \text{(constant forces exerted on particle, one dimension).} \tag{9.9}$$

Equation 9.9 is what we call the **work equation** for a particle. Together with the energy law (Eq. 9.1), this equation allows us to deal with systems that are not closed.

Notice the parallel between our treatments of momentum/impulse and energy/work (**Figure 9.16**). Conservation of momentum gives rise to the momentum law, Eq. 4.18, $\Delta\vec{p} = \vec{J}$, where $\vec{J}$ is the impulse delivered to the system. For an isolated system, the impulse is zero and so the momentum of the system does not change. If the system is not isolated, we can use the impulse equation, Eq. 8.25, $\vec{J} = (\sum\vec{F})\Delta t$, to calculate the change in the momentum of the system. Conservation of energy gives rise to the energy law, Eq. 9.1. The work done on a closed system is zero, and so the energy of the system does not change. If the system is not closed, we can use the work equation, Eq. 9.9, to calculate the change in the energy of the system. When we solve problems, it is possible to choose either a closed system or a system that is not closed. As the next example shows, both choices lead to the same answer. If you are unable to obtain a solution with one approach, try the other.

Figure 9.16 Energy and momentum changes for systems.



Although we derived Eqs. 9.8 and 9.9 for a particle, they can also be used for any rigid object as long as only the kinetic energy of the object changes. In that case, we can use Eq. 9.2 to calculate the change in the energy of the object. Because all particles that make up the object undergo the same displacement $\Delta\vec{r}$, Eq. 9.8 gives the work done by a constant force exerted on the object.

EXAMPLE 9.6 Work done by gravity

A ball of inertia m_b is released from rest and falls vertically. What is the ball's final kinetic energy after a displacement $\Delta x = x_f - x_i$?

1 GETTING STARTED I begin by making a sketch of the initial and final conditions and drawing an energy diagram for the ball (**Figure 9.17**). I choose an x axis pointing upward. Because the ball's internal energy doesn't change as it falls (its shape and temperature do not change), I can treat the ball as a particle. Therefore only its kinetic energy changes. I can also assume air resistance is small enough to be ignored, so that the only external force exerted on the ball is a constant gravitational force. This force has a nonzero force displacement and so does work on the ball. I therefore include this force in my diagram.

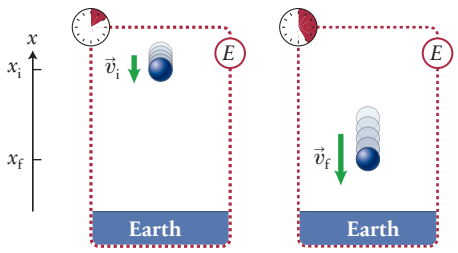
Figure 9.17

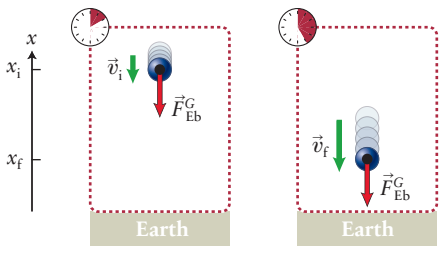
2 DEVISE PLAN If I treat the ball as a particle, Eqs. 9.1 and 9.2 tell me that the change in the ball's kinetic energy is equal to the work done on it by the constant force of gravity, the x component of which is given by Eq. 8.17: $F^G_{\text{Eb}\,x} = -m_b g$. (The minus sign means that the force points in the negative x direction.) To calculate the work done by this force on the ball, I use Eq. 9.8.

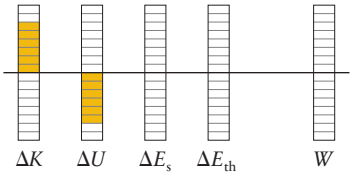
3 EXECUTE PLAN Substituting the x component of the gravitational force exerted on the ball and the force displacement $x_f - x_i$ into Eq. 9.8, I get

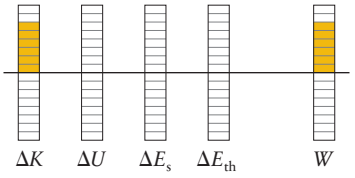
$$W = F^G_{\text{Eb}x}\Delta x_F = -m_b g(x_f - x_i).$$

Because the work is equal to the change in kinetic energy and the initial kinetic energy is zero, I have $W = \Delta K = K_f - 0 = K_f$, so









$$K_f = -m_b g(x_f - x_i). \checkmark$$

4 EVALUATE RESULT Because the ball moves in the negative x direction, $\Delta x = x_f - x_i$ is negative and so the final kinetic energy is positive (as it should be).

An alternative approach is to consider the closed Earth-ball system. For that system, the sum of the gravitational potential energy and kinetic energy does not change, and so, from Eq. 7.13, $\Delta K + \Delta U^G = \frac{1}{2}m_b(v_f^2 - v_i^2) + m_b g(x_f - x_i) = 0$. Because the ball starts at rest, $v_i = 0$, and so I obtain the same result for the final kinetic energy: $\frac{1}{2}m_b v_f^2 = -m_b g(x_f - x_i)$.

QUANTITATIVE TOOLS

Figure 9.18 Two ways to determine the change in kinetic energy of a falling ball.

	Closed-system approach	Open-system approach
Sketch		
Energy diagram		
Energy law	$\Delta E = 0$ $\Delta K + \Delta U^G = 0$	$\Delta E = \Delta K = W$ $W = F^G_{Ebx}\Delta x_F$
Equation to use	$\Delta U^G = m_b g(x_f - x_i)$	$F^G_{Ebx} = -m_b g$
Answer	$\Delta K = -m_b g(x_f - x_i)$	$\Delta K = -m_b g(x_f - x_i)$

The two approaches used in Example 9.6 are shown schematically in Figure 9.18. In the closed-system approach, the increase in kinetic energy is attributed to a decrease in the gravitational potential energy of the Earth-ball system. In the open-system approach, the increase in kinetic energy is attributed to the work done by the force of gravity on the ball. In this case it is meaningless to talk about gravitational potential energy because gravitational potential energy refers to the configuration of Earth and the ball *together*. Because Earth is not part of the system, it would not be clear whether to attribute this potential energy to Earth or to the ball.

9.10 Verify that in Example 9.6 the momentum transferred to the ball by the gravitational force is $\Delta p_x = m_b(v_{x,f} - v_{x,i})$.

9.6 Work done on a many-particle system

Everyday objects cannot always be treated as either single particles or rigid objects. As we saw in Section 8.12, we must consider such objects as systems of many interacting particles. The acceleration of the center of mass of such a system is given by Eq. 8.45:

$$\vec{a}_{cm} = \frac{\Sigma \vec{F}_{ext}}{m}, \tag{9.10}$$

where m is the inertia of the system. Using this result, we can now evaluate the work done by external forces on a many-particle system following an approach analogous to that of a single particle in Eqs. 9.4–9.8.

Consider the motion of a two-particle system over a time interval $\Delta t = t_f - t_i$. If the center of mass of the system moves at velocity $\vec{v}_{cm,i}$ at

QUANTITATIVE TOOLS

some initial instant t_i and has constant acceleration $\vec{a}_{cm}$, then from Eq. 9.4 the velocity of the center of mass at the end of the time interval is

$$\vec{v}_{cm,f} = \vec{v}_{cm,i} + \vec{a}_{cm}\Delta t \tag{9.11}$$

and its displacement is (from Eq. 9.5)

$$\Delta\vec{x}_{cm} = \vec{v}_{cm,i}\Delta t + \tfrac{1}{2}\vec{a}_{cm}(\Delta t)^2. \tag{9.12}$$

Using these expressions, we can evaluate the changes in the translational kinetic energy of the system from Eq. 6.32, $K_{cm} = \frac{1}{2}mv_{cm}^2$:

$$\Delta K_{cm} = K_{cm,f} - K_{cm,i} = \tfrac{1}{2}m(v_{cm,f}^2 - v_{cm,i}^2). \tag{9.13}$$

Following the same derivation used to obtain Eq. 9.7, we calculate for the change in translational kinetic energy of the system

$$\Delta K_{cm} = ma_{cmx}\Delta x_{cm} = (\Sigma F_{extx})\Delta x_{cm} \quad \text{(constant forces, one dimension)}. \tag{9.14}$$

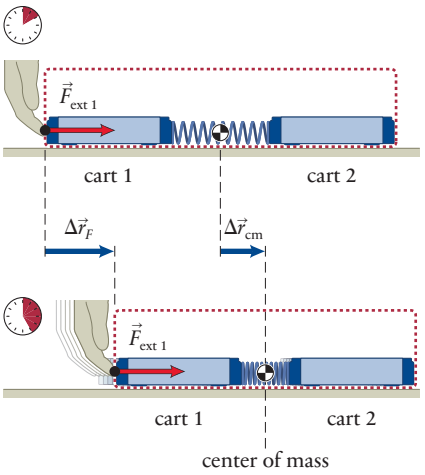
Even though this result looks very much like Eq. 9.7, ΔK_{cm} does not represent the work done by the external force on the system. The reasons are that the translational kinetic energy K_{cm} is only part of the kinetic energy of the system (which we know from Eq. 6.35, $K = K_{cm} + K_{conv}$) and for a system of many interacting particles changes can also occur in the other kinds of energy. Therefore $\Delta K_{cm} \neq \Delta E$. Knowing from Eq. 9.1 that $\Delta E = W$, we see that ΔK_{cm} from Eq. 9.14 cannot be equal to the work done by the external force on the many-particle system:

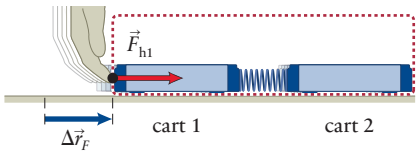
$$\Delta K_{cm} \neq W \quad \text{(many-particle system)}. \tag{9.15}$$

To see this more explicitly, consider the system consisting of two carts connected by a spring, illustrated in **Figure 9.19**. Cart 1 is subject to a single external force $\vec{F}_{ext\,1}$. If we ignore any changes in the carts' internal energies, we can consider the carts to be particles, which means that all of the system's internal energy is stored in the spring. The pushing on cart 1 both accelerates the system and compresses the spring, causing changes in the system's kinetic and internal energies. Unfortunately, we cannot calculate these changes because we don't know how much the spring compresses and we don't know anything about the instantaneous velocities of the carts. Because the work done by external forces on the system is equal to the change in the system's energy E—where E is the sum of all forms of energy—Eq. 9.14 does not provide an expression for the work done on the system.

So, how can we determine the work done by external forces on a many-particle system? Because work is energy transferred, we can use the fact that the work W_{env} done by a system on its environment has the same magnitude as the work W_{sys} done by the environment on the system but carries the opposite sign: $W_{env} = -W_{sys}$. If the system gains, say, 100 J, then conservation of energy dictates that something outside the system must lose 100 J. In **Figure 9.20a**, for example, the external force $\vec{F}_{h1}$ exerted by the hand on cart 1 gives the cart a displacement $\Delta\vec{r}_F$. According to Eq. 8.15, $\vec{F}_{12} = -\vec{F}_{21}$, cart 1 must exert a force $-\vec{F}_{h1}$ on the hand. The work done by cart 1 on the hand over the displacement $\Delta\vec{r}_F$ is, from Eq. 9.8, $-F_{h1x}\Delta x_F$ (Figure 9.20*b*). Because the work done by the two-cart system *on* the hand is $-F_{h1x}\Delta x_F$, the work done *by* the hand on the two-cart

Figure 9.19 An external force does work on a system of two interacting carts.





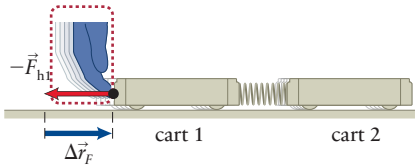


Figure 9.20 The work done by its environment on a system has the same magnitude as the work done by the system on its environment, but the two carry opposite signs: $W_{env} = -W_{sys}$.

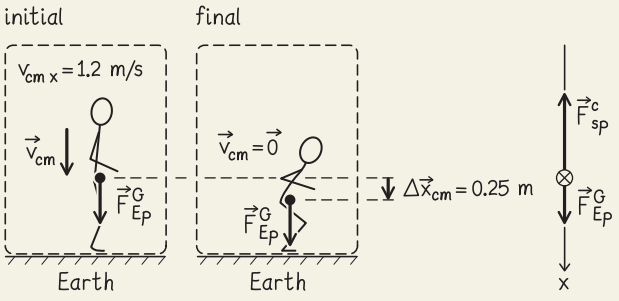
(*a*) Hand does work on carts

(*b*) Carts do work on hand

system must be $+F_{\text{h1}\,x}\Delta x_F$. In general, when an external force is exerted on one of the particles in a two-particle system, the work equation is*

$$W = F_{\text{ext }1x}\Delta x_F \quad \text{(constant nondissipative force, one dimension).} \quad (9.16)$$



This work is equal to the product of the external force and Δx_F, the x component of the displacement *of the point of application of this force*, which is different from Δx_{cm}, the x component of the displacement *of the center of mass*, which appears in Eq. 9.14. Although we obtained this result for the specific case of two carts connected by a spring, the result does not depend on any of the specifics of the system and therefore is valid for any system of two interacting particles subject to a single, constant external force.

EXAMPLE 9.7 Landing on his feet

A 60-kg person jumps off a chair and lands on the floor at a speed of 1.2 m/s. Once his feet touch the floor surface, he slows down with constant acceleration by bending his knees. During the slowing down, his center of mass travels 0.25 m. Determine the magnitude of the force exerted by the floor surface on the person and the work done by this force on him.

❶ **GETTING STARTED** I begin by making a sketch of the initial and final conditions, choosing my person as the system and assuming the motion to be entirely vertical (**Figure 9.21**). I point the $+x$ axis downward in the direction of motion, which means that the x components of both the displacement and the velocity of the center of mass are positive: $\Delta x_{\text{cm}} = +0.25$ m and $v_{\text{cm}x} = +1.2$ m/s. Two external forces are exerted on the person: a downward force of gravity $\vec{F}^G_{\text{Ep}}$ exerted by Earth and an upward contact force $\vec{F}^c_{\text{sp}}$ exerted by the floor surface. Only the point of application of the force of gravity undergoes a displacement, and so I need to include only that force in my diagram. (Source energy and thermal energy balance each other; I ignore them here.)

Figure 9.21

❷ **DEVISE PLAN** Knowing the initial center-of-mass velocity, I can use Eq. 9.13 to calculate the change in the person's translational kinetic energy ΔK_{cm}. To calculate the vector sum of the external forces exerted on the person, I can use the value I obtain for ΔK_{cm} and the displacement $\Delta x_{\text{cm}} = +0.25$ m in Eq. 9.14 to obtain the vector sum of the forces exerted on the person. If I then subtract the force of gravity, I obtain the force exerted by the floor surface on the person. To determine the work done by this force on the person, I need to multiply it by the force displacement. Because the person slows down as he travels downward, his acceleration is upward and so the vector sum of the forces is upward too. To remind myself of this, I draw a free-body diagram in which the arrow for the upward contact force is longer than the arrow for the downward force of gravity.

❸ **EXECUTE PLAN** Because the person ends at rest, his final translational kinetic energy is zero, and Eq. 9.13 gives me

$$\Delta K_{\text{cm}} = 0 - \tfrac{1}{2}mv^2_{\text{cm,i}} = \tfrac{1}{2}(60\text{ kg})(1.2\text{ m/s})^2 = -43\text{ J}.$$

Substituting this value and the displacement of the center of mass into Eq. 9.14 yields

$$\Sigma F_{\text{ext}x} = \frac{\Delta K_{\text{cm}}}{\Delta x_{\text{cm}}} = \frac{-43\text{ J}}{0.25\text{ m}} = -170\text{ N}.$$

To obtain the force exerted by the floor from this vector sum, I add to the sketch a free-body diagram showing the two forces exerted on the person (Figure 9.21).

$$\Sigma F_{\text{ext}x} = F^G_{\text{Ep}x} + F^c_{\text{sp}x}$$

and so $F^c_{\text{sp}x} = \Sigma F_{\text{ext}x} - F^G_{\text{Ep}x}$. The x component of the force of gravity is $F^G_{\text{Ep}x} = mg = (60\text{ kg})(9.8\text{ m/s}^2) = +590$ N and so $F^c_{\text{sp}x} = -170\text{ N} - 590\text{ N} = -760$ N. ✔

To determine the work done by this force on the person, I must multiply the x component of the force by the force displacement. The point of application is at the floor, which doesn't move. This means that the force displacement is zero, and so the work done on the person is zero too: $W = 0$. ✔

❹ **EVALUATE RESULT** The contact force $F^c_{\text{sp}x}$ is negative because it is directed upward, as I expect. Its magnitude is larger than that of the force of gravity, as it should be in order to slow the person down.

*We can apply this line of reasoning only when the force $\vec{F}_{\text{ext }1}$ is nondissipative. As we saw in Section 9.4, if the force exerted at the boundary of a system is dissipative, we don't know how much of the dissipated energy ends up inside the system.

QUANTITATIVE TOOLS

9.11 Compare the rightmost terms of Eqs. 9.14 and 9.16 to determine whether, in any two-particle system subject to a single, constant external force, ΔE is larger than, equal to, or smaller than ΔK_{cm}. Explain your answer.

We can easily generalize Eq. 9.16 to a many-particle system subject to several constant forces. When more than one external agent interacts with the system, we can follow the same argument to calculate the work done by each external agent on the system. If agent 1 exerts a force $\vec{F}_{ext\ 1}$ on a system and the point of application of this force undergoes a displacement $\Delta\vec{r}_{F1}$, then the work done by that agent on the system is $W_1 = F_{ext\ 1x}\,\Delta x_{F1}$.* Likewise, the work done by agent 2 is $W_2 = F_{ext\ 2x}\,\Delta x_{F2}$. The work done by all the agents in the environment on the system is the sum of the work done by each on the system:

$$W = W_1 + W_2 + \cdots = F_{ext\ 1x}\Delta x_{F1} + F_{ext\ 2x}\Delta x_{F2} + \cdots \qquad (9.17)$$

or

$$W = \sum_n (F_{ext\ nx}\Delta x_{Fn} \quad \text{(constant nondissipative forces, one dimension)}, \qquad (9.18)$$

which is the work equation for a many-particle system subject to constant external forces.

Note that to calculate this work we must take the product of each external force and the force displacement *of that force*. If the system is an object that deforms, these displacement values are different in different parts of the system. For that reason both $F_{ext\,nx}$ and Δx_{Fn} in Eq. 9.18 carry a subscript n.

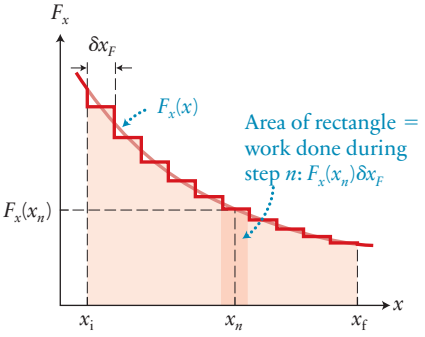
If the force is dissipative, we cannot use this expression because the dissipated energy is distributed on both sides of the system boundary. Dissipative forces are discussed in the next section. The results for a single particle and a system of particles are summarized in **Table 9.1**.

9.12 Show that for a one-particle system, Eqs. 9.14 and 9.18 both reduce to Eq. 9.9.

Table 9.1 Equation of motion and energy accounting for a particle and a system of particles

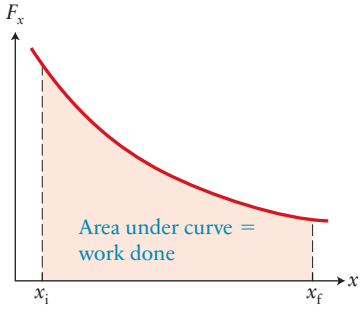
	Single particle or rigid object	System of particles or deformable object
Equation of motion	$\vec{a} = \dfrac{\Sigma\vec{F}}{m}$	$\vec{a}_{cm} = \dfrac{\Sigma\vec{F}_{ext}}{m}$
Energy law	$\Delta E = W$	$\Delta E = W$
Work equation	$W = (\Sigma F_x)\Delta x_F$	$W = \sum_n (F_{ext\,nx}\Delta x_{Fn})$
Kinetic energy change	$\Delta K = W$	$\Delta K_{cm} = (\Sigma F_{ext\,x})\Delta x_{cm}$

*When work is done by more than one force on an object or system, the work done by each force individually inherits the subscripts of the corresponding force.



9.7 Variable and distributed forces

The results obtained in the preceding two sections apply only to forces that are constant and that are applied at well-defined locations in a system. If the forces are not constant or if we cannot determine the force displacement, then the results we obtained do not apply. Examples are the force exerted by a spring, which varies with the amount of compression or stretching, and the frictional force, which is distributed over a surface and for which it is not possible to determine the point of application. Let us examine these two cases in more detail.



What should one do if the force exerted on a system isn't constant? (We call such a force a *variable force*.) For this kind of force, the x component can be written as a function of x: $F_x = F_x(x)$. The trick is to apply the constant-force result over a force displacement small enough to make the force approximately constant over that displacement. **Figure 9.22** shows how, for a force that varies with the position at which that force is applied, we can divide the force displacement into small segments.

Figure 9.22 Evaluating the work done by a variable force $\vec{F}(x)$ on a system.

(*a*) Work approximated by area under steps of constant force

(*b*) As δx_F approaches zero, area under curve approaches work done

Suppose we want to know the work done by the variable force on a system while the point of application of the force moves from x_i to x_f in Figure 9.22. We first divide the force displacement $x_f - x_i$ into N equal smaller force displacements δx_F such that the force is approximately constant across each δx_F (Figure 9.22*a*). Applying Eq. 9.8 to each smaller displacement δx_F, we can write the work done by the variable force on the system during each displacement as

$$W_n = F_x(x_n)\delta x_F, \tag{9.19}$$

where $F_x(x_n)$ is the x component of the force at x_n (this point x_n is located at the center of each interval, as shown in Figure 9.22*a*). This work is the area of the dark shaded rectangle in Figure 9.22*a*. The work done over the entire force displacement from x_i to x_f is then approximately equal to the sum of work W_n over all small force displacements δx_F between x_i and x_f:

$$W \approx \sum_n W_n = \sum_n F_x(x_n)\delta x_F, \tag{9.20}$$

where $\sum_n F_x(x_n)\delta x_F$ represents the sum of all the rectangular areas under the steps between x_i and x_f (the light shaded area in Figure 9.22*a*).

To get a better approximation, we can divide the displacement $x_f - x_i$ into a larger number of smaller force displacements δx_F, so that the variation of the external force over each displacement becomes even smaller and the red stepped curve is closer to the actual (light red) $F_x(x)$ curve.

An exact result is obtained if we let δx_F approach zero (and the number of small displacements approaches infinity), as in Figure 9.22*b*:

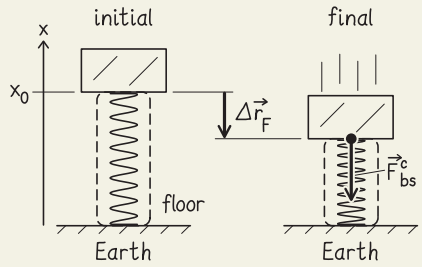
$$W = \lim_{\delta x_F \to 0} \sum_n F_x(x_n)\delta x_F, \tag{9.21}$$

which is precisely the definition of the integral of the x component of the external force with respect to x from x_i to x_f:

$$W = \int_{x_i}^{x_f} F_x(x)dx \quad \text{(nondissipative force, one dimension)}. \tag{9.22}$$

9.13 Show that Eq. 9.22 reduces to Eq. 9.8 when the force is constant.

An example of a force that varies with the position at which it is applied is the force exerted by a spring on a load: $\vec{F}_{sl} = -k(\vec{x} - \vec{x}_0)$ (Eq. 8.20).



QUANTITATIVE TOOLS

EXAMPLE 9.8 Spring work

A brick of inertia m compresses a spring of spring constant k so that the free end of the spring is displaced from its relaxed position. What is the work done by the brick on the spring during the compression?

❶ **GETTING STARTED** I begin by making a sketch of the situation as the free end of the spring is compressed from its relaxed position x_0 to a position x (**Figure 9.23**). Because I need to calculate the work done by the brick on the spring, I choose the spring as my system. Three forces are exerted on the spring: contact forces exerted by the brick and by the floor, and the force of gravity. As usual when dealing with compressed springs, I ignore the force of gravity exerted on the spring (see Section 8.6). Only the force $\vec{F}^{c}_{bs}$ exerted by the brick on the spring undergoes a nonzero force displacement, so I need to show only that force in my diagram. Because the brick and spring do not exert any forces on each other when the spring is in the relaxed position, I do not draw this force in the initial state.

Figure 9.23

❷ **DEVISE PLAN** I need to calculate the work done by the brick on the spring. I could use Eq. 9.22 if I knew the force the brick exerts on the spring. That force is not given, but the force exerted by the brick on the spring and the force exerted by the spring on the brick form an interaction pair: $\vec{F}^{c}_{bs} = -\vec{F}^{c}_{sb}$. I can use Eq. 8.20 to determine $\vec{F}^{c}_{sb}$ and then use it in Eq. 9.22.

❸ **EXECUTE PLAN** Equation 8.20 tells me that the x component of the force exerted by the spring on the brick varies depending on how far the spring is compressed:

$$F_{sbx} = -k(x - x_0),$$

where x_0 is the coordinate of the relaxed position of the free end of the spring. The x component of the force exerted by the brick on the spring is thus

$$F_{bsx} = +k(x - x_0). \tag{1}$$

Because $x_0 > x$, F_{bsx} is negative, which means that $\vec{F}^{c}_{bs}$ points in the same direction as the force displacement. Thus the work done by the brick on the spring is positive. Now I substitute Eq. 1 into Eq. 9.22 and work out the integral to determine the work done by the brick on the spring:

$$W_{bs} = \int_{x_0}^{x} F_{bsx}(x)\,dx = \int_{x_0}^{x} k(x - x_0)\,dx$$

$$= \left[\tfrac{1}{2}kx^2 - kx_0x\right]_{x_0}^{x} = \tfrac{1}{2}k(x - x_0)^2. \checkmark \tag{2}$$

❹ **EVALUATE RESULT** Because the spring constant k is always positive (see Section 8.9 on Hooke's law), the work done by the brick on the spring is also positive. This is what I expect because the work done in compressing the spring is stored as potential energy in the spring.

9.14 In Example 9.8, consider the situation from the instant the brick is released to the instant at which it has zero velocity (when the spring compression is greatest). Draw an energy diagram for a system that comprises (*a*) the spring alone and (*b*) Earth, spring, and brick.

The energy law tells me that the change in the energy of the spring in Example 9.8 is equal to the work done by the brick on it: $\Delta E = W$. As you saw in part *a* of Checkpoint 9.14, only the potential energy of the spring (corresponding to the configuration of the spring) changes, and so $\Delta E = \Delta U_{spring} = W$. The change in the **potential energy of a spring** as its free end is displaced from its relaxed position x_0 to any position x is thus

$$\Delta U_{spring} = \tfrac{1}{2}k(x - x_0)^2. \tag{9.23}$$

This expression also describes the change in potential energy when the spring is stretched by some external force. To stretch the spring, the force exerted on it must point upward in Figure 9.23, which means that instead of $\Delta\vec{r}$ and $\vec{F}^{c}_{bs}$ both pointing downward as they do in compression, these two vectors both point upward. The expression for the work done by the stretching force on the spring (Eq. 2 in Example 9.8) remains the same because the displacement and the force exerted on the spring still both

point in the same direction and so Eq. 9.23 also remains the same. Consequently the potential energy of a spring increases both when the spring is compressed and when it is stretched.

9.15 (Brain twister) As the brick in Example 9.8 moves downward, why is the magnitude of the force it exerts on the spring given by Eq. 1 in Example 9.8 and not by simply the magnitude mg of the gravitational force exerted by Earth on the brick? Hint: Draw a free-body diagram for the brick as it moves downward.

Next we turn to the force of friction. As we discussed in Section 9.4, friction poses a problem for two reasons. First, the energy dissipated by friction ends up being divided between two objects. Second, there is no single point of application for frictional forces—the force is distributed over two surfaces that move relative to each other.

Consider a block sliding across a rough surface. The block is initially moving at some speed v but eventually comes to rest because of friction between it and the surface. **Figure 9.24** shows an energy diagram for the closed block-surface system. Because there are no reversible changes in configuration and no source energy is used, we know that all of the block's kinetic energy is converted to thermal energy. So, if we know the block's initial kinetic energy, we can determine the thermal energy generated from the energy law:

$$\Delta E = \Delta K + \Delta E_{\text{th}} = 0. \tag{9.24}$$

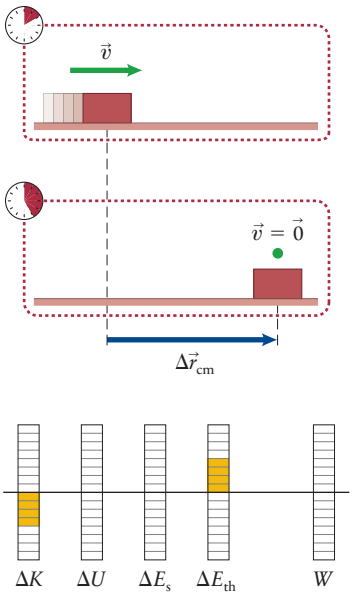
Because the final kinetic energy is zero, we have

$$\Delta E_{\text{th}} = -\Delta K = -(K_{\text{f}} - K_{\text{i}}) = K_{\text{i}}. \tag{9.25}$$

How are these energy changes related to the displacement $\Delta\vec{r}_{\text{cm}}$ over which the block slides to a stop? Let the force of friction exerted by the surface on the block be $\vec{F}^{\text{f}}_{\text{sb}}$. According to Eq. 9.14, the change in the block's translational kinetic energy is equal to the product of the external force exerted on the block and the displacement of its center of mass:

$$\Delta K_{\text{cm}} = F^{\text{f}}_{\text{sb}x}\Delta x_{\text{cm}}. \tag{9.26}$$

Because the frictional force and the block's displacement point in opposite directions, the right side of Eq. 9.26 is negative. Because the block is a rigid object, the translational kinetic energy is all of its kinetic energy, and so $\Delta K_{\text{cm}} = \Delta K$. Substituting Eq. 9.25 then yields an expression for the energy dissipated by friction:



$$\Delta E_{\text{th}} = -F^{\text{f}}_{\text{sb}x}\Delta x_{\text{cm}} \quad \text{(constant dissipative force, one dimension)}. \tag{9.27}$$

When you use this equation, keep in mind that the energy is dissipated on both sides of the surface where the friction occurs. So, even though the right sides of Eqs. 9.26 and 9.27 are the product of a constant force and a displacement, it would not be correct to refer to this product as "the work done by the friction force exerted on the block." Furthermore, Eq. 9.27 holds for travel in only one direction; if the block reverses the direction of travel, you have to apply Eq. 9.26 to each one-way segment separately. If the sum of the distances traveled over all the one-way segments is d_{path}, the change in thermal energy becomes

$$\Delta E_{\text{th}} = F^{\text{f}}_{\text{sb}}d_{\text{path}} \quad \text{(constant dissipative force, one dimension)}, \tag{9.28}$$

where F^{f}_{sb} is the magnitude of the force of friction and where we have dropped the minus sign of Eq. 9.27 because all quantities are positive.

Figure 9.24 Energy diagram for a system in which friction dissipates kinetic energy to thermal energy.

QUANTITATIVE TOOLS

9.16 A 0.50-kg wood block slides 0.50 m on a horizontal floor before colliding elastically with a wall and reversing its direction of travel. If the block has an initial speed of 1.0 m/s and comes to rest exactly at its starting position, what is the magnitude of the frictional force between block and floor?

9.8 Power

Often we are interested not just in knowing how much energy is converted within a system or transferred to a system but also in knowing *how fast* the energy is converted or transferred. The rate at which energy is transferred or converted is called **power.** If the energy of a system changes by an amount ΔE over a time interval Δt, the average power is defined as

$$P_{\text{av}} = \frac{\Delta E}{\Delta t}. \tag{9.29}$$

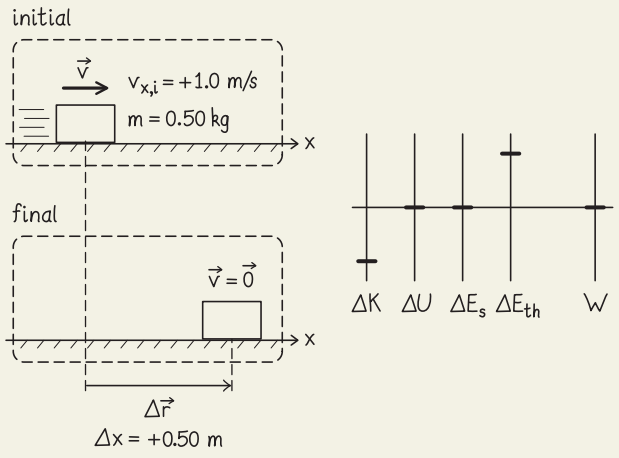
The SI unit of power is the **watt** (W), which is equal to 1 J of energy per second: 1 W ≡ 1 J/s.* A person in good physical condition can deliver about 75 W of average power over a prolonged time interval. This means a healthy person can do work—shovel snow, accelerate an object, and so on—at the rate of about 75 J/s. An athlete can deliver about 400 W over a sustained time interval and up to about 1000 W during short time intervals.

The instantaneous power is

$$P = \lim_{\Delta t \to 0} \frac{\Delta E}{\Delta t} = \frac{dE}{dt}. \tag{9.30}$$

Equation 9.30 gives the rate at which the energy of a system changes. The concept of power can be applied to the rate at which any type of energy changes. For example, the power at which thermal energy is generated is given by

$$P = \frac{dE_{\text{th}}}{dt}. \tag{9.31}$$



EXAMPLE 9.9 Frictional power

A 0.50-kg wood block initially traveling at 1.0 m/s slides 0.50 m on a horizontal floor before coming to rest. What is the average rate at which thermal energy is generated?

❶ **GETTING STARTED** I begin by making a sketch of the situation, listing all the given quantities and drawing an energy diagram for the closed block-floor system (**Figure 9.25**). I note that as the block slides to a stop, all of its kinetic energy is converted to thermal energy.

❷ **DEVISE PLAN** To calculate the average power at which thermal energy is generated, I need to know the amount ΔE_{th} of thermal energy generated and the time interval Δt over which it is generated. The ratio of these two quantities gives the average power (Eq. 9.29). The amount of thermal energy is equal to the initial kinetic energy of the block. If I assume the block has constant acceleration as it comes to a stop, I can use equations from Chapter 3 to determine Δt from the block's initial speed and the distance over which it comes to a stop.

Figure 9.25

(Continued)

*Be careful about distinguishing between italic *W*, our symbol for work, and nonitalic W, the abbreviation for watt, the SI unit of power.

QUANTITATIVE TOOLS

❸ **EXECUTE PLAN** Because the block ends at rest, I know from Eq. 3.4, $v_{x,f} = v_{x,i} + a_x \Delta t$, that

$$a_x = -\frac{v_{x,i}}{\Delta t}.$$

Substituting this result into Eq. 3.8, $x_f = x_i + v_{x,i}\Delta t + \frac{1}{2}a_x(\Delta t)^2$, gives

$$\Delta x = v_{x,i}\Delta t - \tfrac{1}{2}\frac{v_{x,i}}{\Delta t}(\Delta t)^2 = \tfrac{1}{2}v_{x,i}\Delta t$$

or

$$\Delta t = \frac{2\Delta x}{v_{x,i}} = \frac{2(0.50\text{ m})}{1.0\text{ m/s}} = 1.0\text{ s}.$$

The block's initial kinetic energy is $\frac{1}{2}mv_{x,i}^2 = \frac{1}{2}(0.50\text{ kg})(1.0\text{ m/s})^2 = 0.25\text{ J}$, so the thermal energy generated is $\Delta E_{th} = 0.25$ J. From Eq. 9.29, I then obtain for the average power at which this energy is generated: $P_{av} = (0.25\text{ J})/(1.0\text{ s}) = 0.25\text{ W}$. ✔

❹ **EVALUATE RESULT** The value I obtain is rather small—as a gauge, consider that a 25-W light bulb consumes energy at 100 times this rate—but it's unlikely that the energy of a sliding block would be sufficient to generate any light.

Next consider a situation where a system's energy is changed by a constant external force $\vec{F}_{ext}$. One such instance might be when you push a cart. As long as the force you exert on the cart is constant, we can analyze the power being supplied by you to the cart in terms of the x components of the force $F_{ext\,x}$ and the force displacement Δx. We know from Eqs. 9.1 and 9.8 that

$$\Delta E = W = F_{ext\,x}\Delta x. \tag{9.32}$$

Substituting this expression for ΔE into Eq. 9.29 yields

$$P_{av} = \frac{\Delta E}{\Delta t} = F_{ext\,x}\left(\frac{\Delta x}{\Delta t}\right) \tag{9.33}$$

or, with the definition of average velocity,

$$P_{av} = F_{ext\,x}v_{x,av}, \tag{9.34}$$

where $v_{x,av}$ is the x component of the average velocity of the point of application of the force (and because the cart is a rigid object it is also the x component of the average velocity of the cart). The power is positive when $\vec{F}_{ext}$ and $\vec{v}_{av}$ point in the same direction, and in this case the energy of the system increases. When $\vec{F}_{ext}$ and $\vec{v}_{av}$ point in opposite directions, the power is negative and the energy of the system decreases.

To obtain the instantaneous power, we take the limit as Δt in Eq. 9.33 goes to zero, yielding

$$P = F_{ext\,x}v_x \quad \text{(one dimension)}. \tag{9.35}$$

EXAMPLE 9.10 Car drag

A car requires 300 kJ of energy to overcome air resistance and maintain a constant speed of 20 m/s over a distance of 1.0 km. What is the force of air resistance exerted on the car?

❶ **GETTING STARTED** The air resistance causes dissipation of the car's source energy. The problem statement tells me that 300 kJ is dissipated over a distance of 1.0 km when the car moves at 20 m/s.

❷ **DEVISE PLAN** From the speed and the distance traveled, I can calculate the time interval over which the 300 kJ is required. I can then use Eq. 9.29 to calculate the rate at which the energy is converted. Knowing the velocity, I can then obtain the force of air resistance from Eq. 9.35.

❸ **EXECUTE PLAN** At 20 m/s it takes the car 50 s to cover 1.0 km. The rate at which energy is converted is thus $P = (300\text{ kJ})/(50\text{ s}) = 6.0\text{ kW}$. From Eq. 9.35, I obtain

$$F_x = \frac{P}{v_x} = \frac{6.0\text{ kW}}{20\text{ m/s}} = 300\text{ N}. \checkmark$$

QUANTITATIVE TOOLS

4 EVALUATE RESULT The answer I obtain—300 N—is the magnitude of the gravitational force exerted on a 30-kg (65-lb) object and therefore equal in magnitude to the force required to hold up such an object. I know, however, that if I stick my hand out a car window at highway speed, the force exerted by the air on my hand is not much larger than the force required to hold up a small object. The car, being much larger than my hand, intercepts a lot more air, but it is shaped more aerodynamically, and so it is reasonable that the force of air resistance is only 300 N.

9.17 (*a*) A gallon of gasoline contains about 1.4×10^8 J of chemical energy. A car consumes this amount of gasoline in approximately 30 min when cruising along a highway; a plane consumes the same amount in about 1 s when flying at cruising altitude. What is the average power of the energy release in each case? (*b*) A 10-kg load must be hoisted up the side of a building that is 50 m tall. How quickly can an athlete capable of delivering 500 W of power get the job done? (*c*) A 3-kW engine gets the job done six times faster than the athlete. How does the work done by the engine on the load compare with the work done by the athlete on the load?

Chapter Summary

Work done by a constant force (Sections 9.1, 9.2, 9.5, 9.6)

Concepts In order for a force to do work on an object, the point of application of the force must undergo a displacement.

The SI unit of work is the **joule** (J).

The work done by a force is positive when the force and the force displacement are in the same direction and negative when they are in opposite directions.

Quantitative Tools When one or more constant forces cause a particle or a rigid object to undergo a displacement Δx in one dimension, the work done by the force or forces on the particle or object is given by the **work equation:**

$$W = (\Sigma F_x)\Delta x_F. \tag{9.9}$$

In one dimension, the work done by a set of constant nondissipative forces on a system of particles or on a deformable object is

$$W = \sum_n (F_{\text{ext}\,nx}\Delta x_{Fn}). \tag{9.18}$$

If an external force does work W on a system, the **energy law** says that the energy of the system changes by an amount

$$\Delta E = W. \tag{9.1}$$

For a closed system, $W = 0$ and so $\Delta E = 0$.

For a particle or rigid object, $\Delta E_{\text{int}} = 0$ and so

$$\Delta E = \Delta K. \tag{9.2}$$

For a system of particles or a deformable object,

$$\Delta K_{\text{cm}} = (\Sigma F_{\text{ext}\,x})\Delta x_{\text{cm}}. \tag{9.14}$$

Energy diagrams (Sections 9.3, 9.4)

Concepts An **energy diagram** shows how the various types of energy in a system change because of work done on the system. (See the Procedure box on page 288.)

In choosing a system for an energy diagram, avoid systems for which friction occurs at the boundary because then you cannot tell how much of the thermal energy generated by friction goes into the system.

Variable and distributed forces (Section 9.7)

Concepts The force exerted by a spring is variable (its magnitude and/or direction changes) but nondissipative (no energy is converted to thermal energy).

The frictional force is dissipative and so causes a change in thermal energy. This force is also a distributed force because there is no single point of application.

Quantitative Tools The work done by a variable nondissipative force on a particle or object is

$$W = \int_{x_i}^{x_f} F_x(x)dx. \tag{9.22}$$

If the free end of a spring is displaced from its relaxed position x_0 to position x, the change in its potential energy is

$$\Delta U_{\text{spring}} = \tfrac{1}{2}k(x - x_0)^2. \tag{9.23}$$

If a block travels a distance d_{path} over a surface for which the magnitude of the force of friction is a constant F^{f}_{sb}, the energy dissipated by friction (the thermal energy) is

$$\Delta E_{\text{th}} = F^{\text{f}}_{\text{sb}} d_{\text{path}}. \tag{9.28}$$

Power (Section 9.8)

Concepts Power is the *rate* at which energy is either converted from one form to another or transferred from one object to another.

The SI unit of power is the **watt** (W), where 1 W = 1 J/s.

Quantitative Tools The **instantaneous power** is

$$P = \frac{dE}{dt}. \tag{9.30}$$

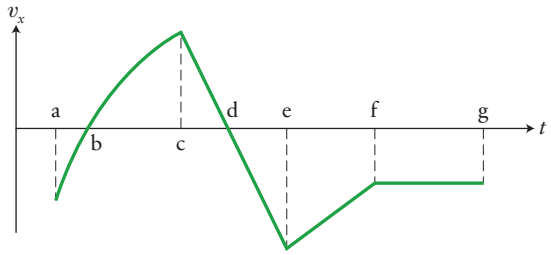
If a constant external force $F_{\text{ext}x}$ is exerted on an object and the x component of the velocity at the point where the force is applied is v_x, the power this force delivers to the object is

$$P = F_{\text{ext}x}v_x. \tag{9.35}$$

Questions and Problems

For instructor-assigned homework, go to Mastering Physics

Dots indicate difficulty level of problems: • = *easy*, •• = *intermediate*, ••• = *hard*; CR = *context-rich problem.*



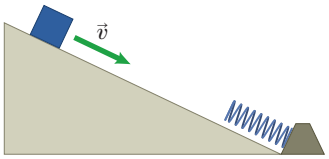
9.1 Force displacement

1. If a large force is applied to an object, does it necessarily follow that work in done on it? •
2. Hitting a door with your bare fist hurts more than hitting a sofa cushion. In work terms, explain why this is so. •
3. If you drop a brick from a height of 50 mm onto your toe, it probably won't hurt much, but if you drop the brick from a height of 0.5 m, it will hurt. The force of gravity exerted on the brick is the same in both cases. Explain why it hurts more from the increased height. ••
4. An object moves with constant velocity. What can you say about the work done on a system that includes only this object? ••
5. You hold a small steel ball in your hand above a laundry basket. Then you throw it straight up and watch as it rises, falls, and comes to rest in the pile of dirty laundry. Ignoring friction, discuss the forces exerted on the ball, the force displacements associated with those forces, and the work done by each force during this process. ••

9.2 Positive and negative work

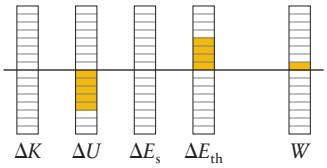
6. The x component of velocity of a particle as a function of time is shown in Figure P9.6. Over what intervals is the work done on the particle (*a*) positive, (*b*) negative, (*c*) zero? •

Figure P9.6



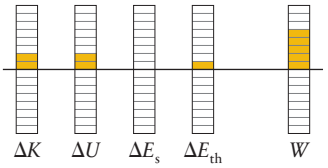
7. You try to push a heavy box along the floor while you are dressed in socks, but your feet keep slipping. When you put on some shoes, your feet no longer slip, and you are able to do work on the box as you push it. Has the friction force between your shoes and the floor done positive or negative work? •
8. You are in an elevator moving between two floors of a building at constant speed. Compare the work done on you by the elevator when you are moving upward to a higher floor to the work done when you are moving downward to a lower floor. ••
9. As a car accelerates from rest to highway speed, a pedestrian watching the motion sees positive work done on the car because its kinetic energy increases. However, from the reference frame of someone driving in the same direction at highway speed, the car is initially moving (backward) and then becomes stationary, corresponding to negative work. Which observer is right? ••
10. A system consists of two interacting particles 1 and 2, with particle 1 confined to an x axis and the system in equilibrium when particle 1 is at a given position on that axis. If displacing particle 1 in either direction from this position requires positive work to be done on the system by an external force, what is the shape of the potential energy curve (as a function of position) for the system in the region near equilibrium? •••

9.3 Energy diagrams



11. Give examples of cases where work is done on a system without changing its kinetic energy. •
12. Taking off on a runway, a small jet experiences a forward force of 90,000 N exerted by the engine and a backward force of 16,000 N exerted by the air. Choose a system and draw an energy diagram using the beginning and end of the runway as your initial and final positions. ••
13. A block launched at speed v down an incline slides down the incline (there is friction between the block and incline) and into a spring (Figure P9.13), where it slows to zero speed as the spring compresses. (*a*) Draw an energy diagram for this process using a system consisting of the block, spring, Earth, and incline. If there is more than one object causing energy conversions, use a separate bar for each. (*b*) Repeat part *a* using a system of just the block and incline. (*c*) Why can't you use the block alone as your system? ••

Figure P9.13

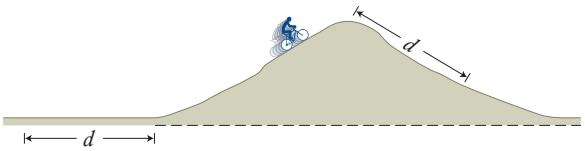


14. What, if anything, is wrong in the energy diagram in Figure P9.14 for a system comprising Earth, an inclined plane, and a block sliding along the incline? The block slides down the incline at constant speed. The only forces exerted on the block are the force of gravity and friction with the incline. ●●

Figure P9.14

15. What possible scenario is described by the energy diagram in Figure P9.15? ●●●

Figure P9.15



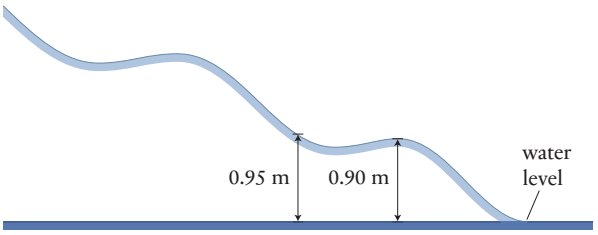
9.4 Choice of system

16. You are lifting a ball at constant velocity. (*a*) When the system is the ball, is work done on the system? If so, by what agent(s)? (*b*) Describe the potential energy of this system during the lift. (*c*) When the system comprises the ball and Earth, is work done on the system? If so, by what agent? (*d*) Describe how the potential energy of the ball-Earth system changes during the lift. ●
17. You throw a ball straight up into the air. If air resistance affects the motion of the ball, which takes longer: the upward trip or the downward trip? Analyze using three different systems. ●
18. A tomato is launched vertically from a spring-loaded toy cannon placed on the pavement. The tomato rises to some maximum height and then falls back, but you have removed the cannon so that the tomato splats on the pavement. Discuss the energy conversions during this process using the following systems: (*a*) tomato, cannon, air, Earth, pavement; (*b*) tomato, cannon, air, pavement; (*c*) tomato, air, pavement; and (*d*) tomato. ●●
19. A ball in motion collides elastically with an identical ball at rest. If we treat each ball as a separate system, is the work done on each ball the same? ●●

9.5 Work done on a single particle

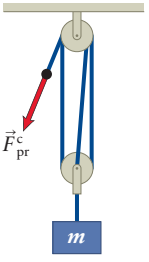
20. You throw a 100-g ball upward with a speed of 19.8 m/s. How much work does the force of gravity do on the ball during its trip to its maximum height? ●
21. At the end of a delivery ramp, a skid pad exerts a constant force on a package so that the package comes to rest in a distance d. When the pad is replaced by one that requires a distance of $2d$ to stop the same package, what happens to the length of time it takes for the package to stop? ●
22. At the end of a delivery ramp, a skid pad exerts a constant force on a package so that the package comes to rest in a distance d. The ramp is changed so that the same package arrives at the skid pad at a higher speed and the stopping distance is $2d$. What happens to the time interval required for the package to stop? ●
23. A 48-kg acrobat must jump high and land on his brother's shoulders. To accomplish this, she leaps from a crouched position to a height where her center of mass is 1.60 m above the ground. Her center of mass is 320 mm above the ground in the crouch and 900 mm above the ground when her feet leave the ground. (*a*) What is the average force exerted on her by the ground during the jump? (*b*) What is her maximum speed? ●●
24. A beetle that has an inertia of 4.0×10^{-6} kg sits on the floor. It jumps by using its muscles to push against the floor and raise its center of mass. (*a*) If its center of mass rises 0.75 mm while it is pushing against the floor and then continues to travel up to a height of 300 mm above the floor, what is the magnitude of the force exerted by the floor on the beetle? (*b*) What is the beetle's acceleration during the motion? ●●
25. A bicyclist pedals a distance d at constant speed on a level stretch of road. She then pedals up a hill and passes slowly over the top. As she coasts down the other side of the hill, she applies the brakes and comes to a stop when she is a distance d past the top (Figure P9.25). Choose an appropriate system and draw an energy diagram from the instant the bicyclist begins her climb until the instant she has stopped on the downslope. ●●

Figure P9.25



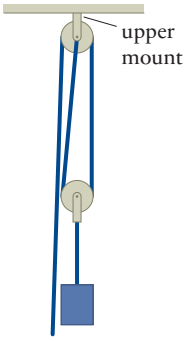
26. In emergency braking, a certain car requires 7.0 m to come to a stop from an initial speed of 10 m/s. Use an argument based on work done on the car to determine the braking distance required if the car's initial speed is 30 m/s. ●●
27. At instant t_0, you are sitting on a dock and you begin using a rope to lower a 4.0-kg lobster trap into the water, 1.4 m below. You lower the trap at a constant speed of 1.0 m/s. At instant t_1 it just reaches the water surface 1.4 m below the dock. You slacken the rope and the trap continues to move downward at a constant speed of 1.0 m/s until at instant t_2 the trap reaches the bottom of the 10-m-deep bay. Choose a system that includes the water, Earth, and the trap. (*a*) Do you do any work on the system in the interval from t_0 to t_2? (*b*) What forces are exerted on the trap during the interval from t_0 to t_2? (*c*) Draw an energy diagram for the interval from t_0 to t_2, showing a correct numerical scale. ●●

28. A 1.1-kg lobster climbs into the trap of Problem 27, and at instant t_3 you begin to haul the trap up onto the dock. The trap moves at a constant 0.40 m/s through the water, and it breaks the surface of the water at instant t_4. You adjust your pull so that it continues moving at that speed until it reaches the height of the dock at instant t_5. Use a system of water, Earth, trap, and lobster. (*a*) Do you do any work on the system in the interval from t_3 to t_5? (*b*) What forces are exerted on the trap as it rises? (*c*) Draw an energy diagram for this system from instant t_3 to instant t_5. In your diagram, there are two kinds of energy you have to combine because you have no way to separate them from each other. Indicate this in your labels. ●●



29. A 30-kg child slides down the amusement-park wave slide shown in Figure P9.29. When they are 0.95 m above the water level their speed is 2.2 m/s. At the top of the final hump, at a height of 0.90 m above the water level, their speed is also 2.2 m/s. What is the increase in the thermal energy of the child and the slide as they move between these two points? ●●

Figure P9.29



30. In the block-and-tackle arrangement shown in Figure P9.30, three segments of the single rope pull on the block. (*a*) Show that the magnitude F_{pr}^{c} of the force exerted by a person on the rope to raise the block at constant speed is $mg/3$, where m is the inertia of the block. (*b*) One worker uses this arrangement to lift a heavy block, while another hauls up an identical block with a straight rope. After both blocks have been raised to the same second-floor window, has either worker done more work than the other? If so, which worker has done more work? ●●

Figure P9.30

31. The pair of pulleys shown in Figure P9.31 is used to lift a 50-kg block 0.25 m. The constant acceleration of the block during the lift is +2.5 m/s^2, and the pulleys and rope have negligible inertia and negligible friction. What is the tension (*a*) in the pulling rope and (*b*) in the rope from which the block hangs? (*c*) What force is exerted by the upper mount on the top pulley? (*d*) How much work is done by the person pulling the rope in lifting the block 0.25 m? (*e*) By how much does the kinetic energy of the block change in this process? (*f*) How much work is done on the block by the rope attached to it? (*g*) How much work does the ceiling do in this process? (*h*) How much work does Earth do on the block? (*i*) Draw energy diagrams for three systems during the lifting: block; block and Earth; block, Earth, pulleys, rope, and person. ●●●

Figure P9.31

9.6 Work done on a many-particle system

32. You push a blob of gelatin with a constant force of 3.0 N across a wet table on which it slides easily. Because the blob shape distorts, its center of mass moves only 30 mm during the time interval in which the point of application of your force moves 50 mm. (*a*) What is the work done by you on the blob? (*b*) By how much does your force change the kinetic energy of the center of mass? ●

33. A 1000-kg car traveling at 5.0 m/s runs into the side of an underpass. The concrete wall is not affected, but the car crumples such that in the time interval from the instant of impact to the instant at which the car comes to rest, its center of mass travels forward 0.50 m. What are (*a*) the magnitude of the average force exerted on the car, (*b*) the work done by the wall on the car, and (*c*) the change in kinetic energy of the system? ●

34. A 60-kg ice skater stands facing a wall with his arms bent and then pushes away from the wall by straightening his arms. At the instant at which his fingers lose contact with the wall, his center of mass has moved 0.50 m, and at this instant he is traveling at 3.0 m/s. What are (*a*) the average force exerted by the wall on him, (*b*) the work done by the wall on him, and (*c*) the change in the kinetic energy of his center of mass? ●

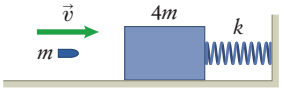
35. Two 0.25-kg carts, one red and one green, are stationary on a low-friction track. The carts are initially separated by 0.50 m. You push on the red one with a constant force of 1.5 N toward the green one. When the carts meet, they join together, and you continue to push with the same constant force as the connected carts move a further 0.75 m along the track, at which point you remove your hand. (*a*) What is the work done by you on the two-cart system? (*b*) How far does the system's center of mass move while you are applying the force? (*c*) By what amount does the force change the kinetic energy of the system? ●●

36. Two 0.50-kg carts are pushed toward each other from starting positions at either end of a 6.0-m low-friction track. Each cart is pushed with a force of 3.0 N, and that force is exerted for a distance of 1.0 m. (*a*) What is the work done on the two-cart system? (*b*) What is the change in kinetic energy of the system? (*c*) What is the kinetic energy of the center of mass of the system? ●●

37. You have a 2.0-m chain lying on the floor alongside ten 0.10-kg cubical blocks, each 0.20 m on a side. Each block is resting on the floor, and the inertia of the chain is 1.0 kg. Which process requires less work: lifting one end of the chain so that the chain hangs vertically with the bottom link just touching the floor, or stacking the blocks in a column ten blocks tall? ••

38. A 1.0-kg cart and a 0.50-kg cart sit at different positions on a low-friction track. You push on the 1.0-kg cart with a constant 2.0-N force for 0.15 m. You then remove your hand, and the cart slides 0.35 m and strikes the 0.50-kg cart. (*a*) What is the work done by you on the two-cart system? (*b*) How far does the system's center of mass move while you are pushing the 1.0-kg cart? (*c*) By what amount does your force change the kinetic energy of the system's center of mass? ••

39. Two 1.0-kg blocks, one gray and one tan, are lined up along a horizontal x axis. The gray block is at $x = -4.0$ m, and the tan one is at $x = +4.0$ m. A constant force of 1.0 N is exerted on the gray block in the positive x direction through a distance of 2.0 m. Taking the two blocks as the system and ignoring friction, calculate the following over the interval required for the gray block to move from $x = -4.0$ m to $x = -2.0$ m: (*a*) the work done on the system, (*b*) the change in the energy of the system, (*c*) the change in the system's translational kinetic energy, and (*d*) the value of $F\Delta x_{cm}$, where $F = 1.0$ N and Δx_{cm} is the displacement of the system's center of mass. (*e*) If the blocks collide totally inelastically, what is the energy of the system after the collision? ••



40. Two identical 0.50-kg carts, each 0.10 m long, are at rest on a low-friction track and are connected by a spring that is initially at its relaxed length of 0.50 m and is of negligible inertia. You give the cart on the left a push to the right (that is, toward the other cart), exerting a constant 5.0-N force. You stop pushing at the instant when the cart has moved 0.40 m. At this instant, the relative velocity of the two carts is zero and the spring is compressed to a length of 0.30 m. A locking mechanism keeps the spring compressed, and the two carts continue moving to the right. (*a*) What is the work done by you on the two-cart system? (*b*) How far does the system's center of mass move while you are pushing the left cart? (*c*) By what amount do you change the system's kinetic energy? ••

41. Because the soles of your shoes have cleats, you can exert a backward force of 100 N on ice, allowing you to exert a similar forward force if you throw an object. A 10-kg picnic cooler is at rest on a frozen pond, and you want to get it to shore, up the bank, and stuck in the snow. From past experience, you know that, in order to move up the bank and stick, the cooler needs to be moving at 3.0 m/s at the instant it starts up the bank. Standing 1.0 m from the cooler and not wanting to walk to it, you decide to apply a constant force to throw 1.0-kg snowballs at it to get it moving. If each snowball smashes into the cooler in a totally inelastic collision, what minimum number of snowballs must you throw? •••

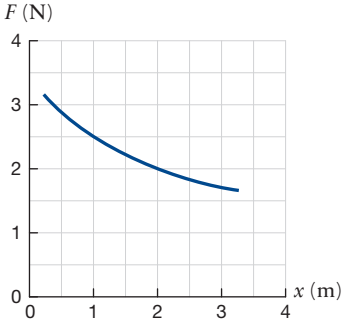
42. A bullet of inertia m traveling at speed v is fired into a wooden block that has inertia $4m$ and rests on a level surface. The bullet passes through the block and emerges with speed $v/3$, taking a negligible amount of the wood with it. The block moves to the right but comes to rest after traveling a distance d. (*a*) What is the magnitude of the frictional force between the block and the surface while the block is moving? (*b*) What is the ratio of the energy dissipated as the bullet passes through the block to the energy dissipated by friction between the surface and the bottom face of the block? •••

43. You fire a bullet of inertia m into the block shown in Figure P9.43. The bullet is initially traveling at speed v, and the inertia of the block is $4m$. The surface on which the block sits is rough, and the spring has spring constant k. The bullet becomes embedded in the block. If the spring compresses a maximum distance d, what is the magnitude of the frictional force exerted by the surface on the block while the block is moving? •••

Figure P9.43

9.7 Variable and distributed forces

44. Spring A is stiffer than spring B. You stretch the springs such that the energy stored in each is the same. (*a*) Which spring has the greater change in length from its relaxed position? (*b*) Which spring requires the greater applied force? •

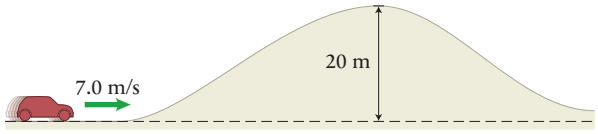


45. Which arrangement in Figure P9.45 requires more work to give the block a rightward displacement $\vec{d}$? The springs, blocks, and surfaces are identical in the two arrangements and the springs are initially at their relaxed length. •

Figure P9.45

46. Figure P9.46 shows the force $F(x)$ plotted as a function of position x. (*a*) What average constant force applied between $x = 1$ m and $x = 3$ m will do the same amount of work? (*b*) What is the work done by $F(x)$ as the object moves from $x = 3$ m to $x = 1$ m? •

Figure P9.46

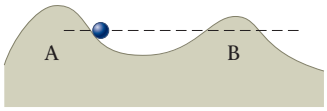


47. Compressing a certain spring to 50% of its relaxed length requires 28 J of work. How much work would be required to compress the same spring by only half as much, to 75% of its relaxed length? •
48. A force varies with time according to the expression $F = a\Delta t$, where $a = 2.0$ N/s. From this information, can you determine the work done on a particle that experienced this force over a displacement of 0.50 m? ••
49. In pushing a 0.024-kg dart into a toy dart gun, you have to exert an increasing force that tops out at 6.0 N when the spring is compressed to a maximum value of 0.12 m. (*a*) What is the launch speed of the dart when fired horizontally? (*b*) Does your answer change if the dart is fired vertically? ••
50. The work done by a certain force is given by $W(\Delta x) = a\Delta x + b(\Delta x)^3$. Write an expression for the force as a function of Δx. ••
51. A 6.0-kg bowling ball is held 10 mm above a mattress and then released from rest and allowed to fall, sinking into the mattress. Model the mattress as a single spring with spring constant $k = 500$ N/m. (*a*) Calculate the ball's kinetic energy, the gravitational potential energy of the system (ball, spring, and Earth), and the elastic potential energy at the following compressions: 0, 0.050 m, 0.10 m, 0.15 m, 0.20 m. (*b*) What is the maximum compression of the mattress? Ignore the inertia of the spring. ••
52. In a carnival game, the player throws a ball at a haystack. For a typical throw, the ball leaves the hay with a speed exactly one-half of the entry speed. (*a*) If the frictional force exerted by the hay is a constant 6.0 N and the haystack is 1.2 m thick, derive an expression for the typical entry speed as a function of the inertia of the ball. Assume horizontal motion only, and ignore any effects due to gravity. (*b*) What is the typical entry speed if the ball has an inertia of 0.50 kg? ••
53. A proton has mass m_p and charge $+e$. The force it exerts on another proton at a distance r is given by $F(r) = \frac{1}{4\pi\epsilon_0}\frac{e^2}{r^2}$ where $\frac{1}{4\pi\epsilon_0} \approx 9 \times 10^9 \text{N} \cdot \text{m}^2/\text{C}^2$, and $e = 1.6 \times 10^{-19}$ C. How much work is needed to increase the separation between the protons from R to $9R$? ••
54. You devise a wind-up car powered by a spring for trips to the grocery store. The car has an inertia of 500 kg and is 4.2 m long. It should be able to accelerate from rest to 20 m/s at least 50 times before the spring needs winding. The spring runs the length of the car, and a full winding compresses it to half this length. In order to meet the acceleration requirement, what must the value of the spring constant be? ••
55. A 0.15-kg cart on wheels is at rest at the origin of an x axis between (but not connected to) two relaxed springs aligned along that axis. When the cart is pushed to the left of the origin, the left spring ($k_l = 4.0$ N/m) is compressed and exerts a force on the cart. When the cart is pushed to the right of the origin, the right spring ($k_r = 6.0$ N/m) is compressed and exerts a force on the cart. (*a*) Plot the force exerted on the cart as a function of its displacement. (*b*) If the cart is given an initial speed of 4.0 m/s at the origin $x = 0$, it might be headed to the left or to the right. How far does it go in each case? (*c*) What is the work done on the cart as it moves from $x = 0$ to its extreme right position and from $x = 0$ to its extreme left position? Ignore any friction effects. •••
56. To complement the baseball-pitching machines at the sports complex where you work, you have designed a catching machine using a mitt, a spring, and a latch that locks the spring in place when the ball has stopped moving. Your boss wants to know the speed of the baseballs coming out of a pitching machine that's been breaking down lately, and you figure you can use the compression of the spring in your catching machine to determine this speed. The mitt that catches the balls has three times the inertia of one ball. Derive an expression for the speed of a thrown ball in terms of the ball's inertia, the distance the spring is compressed, and the spring constant. Take the catch to be a totally inelastic collision between mitt and ball. •••

9.8 Power

57. A particular cyclist can produce an average power output of 180 W when cycling on level ground. While doing this, their speed is 9.5 m/s. What is the magnitude of the net external dissipative force (predominantly air resistance) acting on the cyclist and their bike? •
58. What is the average power delivered when you raise a 2-kg object by 50 cm in 50 ms? •
59. Hiking trails on steep slopes often zigzag back and forth rather than running in a straight path up the slope. What does having a zigzag path accomplish, given that getting to the top of the slope requires the same amount of energy regardless of the path? •
60. The 1000-kg car at the bottom of the hill in Figure P9.60 wants to make it to the top of the hill. What should be the minimum power output of the engine given that 30% of the engine's power and 30% of the car's kinetic energy are lost, and that it takes the car 20 min to make it to the top? ••

Figure P9.60



61. A constant external force F is the only force acting on an object. What is the work done on the object by F as a function of time? ••
62. A team of dogs accelerates a 200-kg dogsled from 0 to 5.0 m/s in 3.0 s. (*a*) What is the magnitude of the force exerted by the dogs on the sled? (*b*) What is the work done by the dogs on the sled in the 3.0 s? (*c*) What is the instantaneous power of the dogs at the end of the 3.0 s? (*d*) What is their instantaneous power at 1.5 s? Assume that the acceleration is constant. ••
63. A 20-kg child wants to slide along a horizontal yard toy that consists of a slick plastic sheet covered with a thin layer of water to reduce friction to almost zero. To cause him to slide, you squirt him with a stream of water from a hose. (*a*) If the water from the hose exerts a constant force of 5.0 N on the child, what is the work done by the water in the interval from $t = 0$ to $t = 1.0$ s? (*b*) What is the instantaneous power delivered by the water at $t = 1.0$ s? ••

64. A cog system on the beginning segment of a roller coaster needs to get 25 occupied cars up a 100-m vertical rise over a time interval of 60 s. Each car experiences a gravitational force of 5670 N. The cars start at rest and end up moving at 0.50 m/s. (*a*) How much work is done by the cog system on the cars? (*b*) What average power must the cog system supply? (*c*) What would happen to the amount of work done by the cog system if the cars had to be lifted the same distance in 30 s? ●●
65. A box slides across a frozen pond toward the left shore as two children standing on opposite shores pull on the box with ropes. The child on the left shore pulls with a force of 3.0 N, and the child on the right shore pulls with a force of 2.0 N. At a certain instant, the speed of the box is 3.0 m/s. (*a*) At that instant, what is the power resulting from each force? (*b*) What is the power resulting from both forces? (*c*) Do your answers to parts *a* and *b* change as the box slides? ●●
66. A motor must lift a 1000-kg elevator cab. The cab's maximum occupant capacity is 400 kg, and its constant "cruising" speed is 1.5 m/s. The design criterion is that the cab must achieve this speed within 2.0 s at constant acceleration, beginning from rest. (*a*) When the cab is carrying its maximum capacity, at what rate must the motor deliver energy to get the cab up to cruising speed? (*b*) At what constant rate must the motor supply energy as the fully loaded cab rises after attaining cruising speed? ●●●

Additional Problems

67. A box of inertia 10 kg is suspended by a vertical rope and lowered through a distance of 10 m with a constant speed. How much work is done on the box by the gravitational force? How much work is done by the tension in the rope? ●
68. Is it possible for a force to be exerted on an object *along the direction of the object's motion* and still produce no change in the object's kinetic energy? If yes, give an example. If no, explain why not. ●
69. A shopping cart that has an inertia of 12 kg when empty is loaded with 38 kg of groceries. A child pushing the loaded cart loses control, and the cart rolls into a concrete lamppost, which sustains no damage. The cart is moving at 2.0 m/s when it strikes the lamppost, and the groceries all crash forward on impact, moving the center of mass forward by 0.10 m before everything comes to a halt. What are (*a*) the average force exerted by the post on the cart-groceries system, (*b*) the work done by the post on the system, and (*c*) the change in kinetic energy of the system's center of mass? ●
70. An object is moving in a circle with constant speed. Its kinetic energy is constant since the speed does not change. Would you conclude that the total external force acting on it is zero? ●●
71. To be rescued from the roof of a burning building, a 70-kg man must be able to jump straight up and catch hold of a rope ladder hanging from a helicopter. He has to raise his center of mass 2.00 m above the roof to do so. (*a*) If he crouches down such that his center of mass is 0.50 m above the roof and his feet leave the roof when his center of mass is 1.05 m above the roof, what minimum force must he exert on the roof to reach the ladder? (*b*) A typical candy bar contains about 850 kJ of food energy. How many candy bars does this jump require? ●●
72. About how much work does a trash collector do in the course of an 8-hour shift? ●●
73. A constant, nondissipative external force is applied to a solid block, and it is found that the rate at which energy is delivered by the force is constant as the block moves horizontally. What does this imply for the motion of the block? ●●
74. An object is suspended from the ceiling by a spring aligned along a vertical x axis, with upward defined as the positive x direction. When the spring is at its relaxed length, the object is at the origin of the axis. The object is pulled down to position $-x_1$, held at rest, and released. Consider its motion from the instant of release until the instant it returns to $-x_1$. Ignore friction, air drag, and the inertia of the spring. (*a*) What force(s) is exerted on the object during the round trip, and in what direction(s)? (*b*) How much work is done on the object by the spring as the object travels away from $-x_1$ and back to $-x_1$? ●●
75. You are midway up hill A in Figure P9.75. Across the valley is the shorter hill B, the summit of which is slightly higher than your present spot. You want to roll a ball so that it crests hill B. To get the ball moving, you can roll it either up or down hill A, giving the ball the same initial speed in both cases. (*a*) Which roll direction is more likely to get the ball to crest B, or does it matter? Ignore any energy dissipation. (*b*) In what way would your answer change if you take energy dissipation into account? ●●

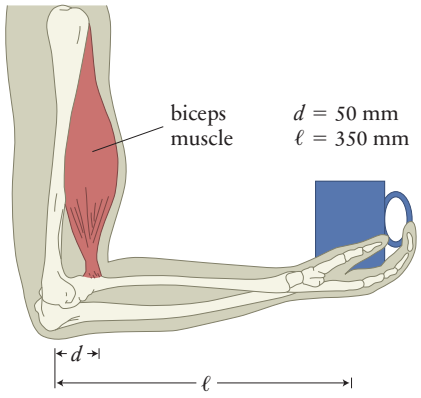


Figure P9.75

76. A 10-kg dog jumps up in the air to catch a ball. The dog's center of mass is normally 0.20 m above the ground, and he is 0.50 m long. The lowest he can get his center of mass is 0.10 m above the ground, and the highest he can get it before he can no longer push against the ground is 0.30 m. If the maximum force the dog can exert on the ground in pushing off is 2.5 times the gravitational force Earth exerts on him, how high can he jump? ●●
77. Assume that when you stretch your torso vertically as much as you can, your center of mass is 1.0 m above the floor. The maximum force you can exert on the floor in pushing off is 2.3 times the gravitational force Earth exerts on you. How low do you have to crouch in order to jump straight up and have your center of mass be 2.0 m above the floor? Is this crouch practical? ●●
78. The 2000-kg cab of a freight elevator is rated to carry a maximum load of 1200 kg, but a careless worker fills the cab with freight that has a combined inertia of 1400 kg. The worker then raises the cab 3.1 m at a steady 2.0 m/s. You notice an unfamiliar whine and come over to investigate. As supervisor, you know that the motor has a 10% tolerance in its rated power output, and you must decide whether there's going to be trouble. ●●● CR

10.9 Work as the product of two vectors
10.10 Coefficients of friction

So far, we have restricted our study of physics to events that take place along a straight line—that is, in one dimension. In this chapter we develop the tools that allow us to deal with motion in a plane—in other words, motion that takes place in two dimensions. As you will see, any problem in two dimensions can be reduced to two one-dimensional problems (which you already know how to solve). After discussing the techniques that allow us to deal with vector quantities in two dimensions, we study the decomposition of two-dimensional force vectors. This decomposition allows us to examine more closely the contact forces that arise at the surface between two objects, which leads us to the subject of friction. Finally, we extend the concept of work so that it applies to situations where the force and force displacement vectors are not along the same line.

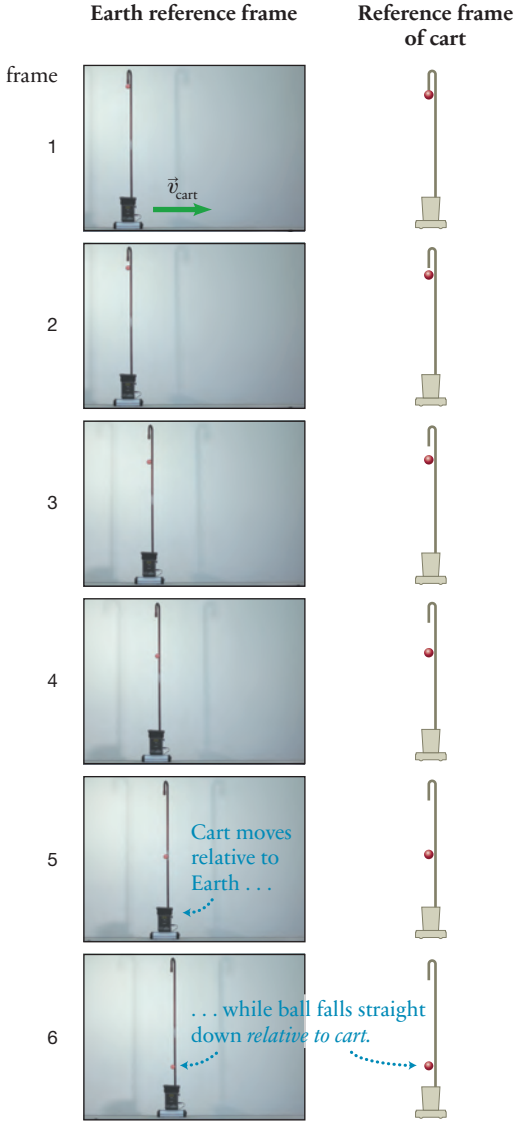
10.1 *Straight* is a relative term

To begin our discussion of motion in a plane, look at the video clip in **Figure 10.1**, which shows the motion of a ball dropped from the top of a pole attached to a cart that is moving at constant velocity along a horizontal track. You already know the resulting motion of the ball: It accelerates downward because of the force of gravity exerted on it (see Section 8.8). Indeed, the ball falls alongside the pole. As we discussed in Chapter 6, this is the way the motion must be because the laws of physics are the same in all inertial reference frames, regardless of whether the reference frames are at rest or moving at constant velocity with respect to the surface of Earth.

To extend this example to a more common situation, consider what happens when you drop an object inside the cabin of an airplane cruising at constant velocity. That object falls to the cabin floor in a straight line, exactly as it would if the airplane were at rest on the ground. Likewise, in the reference frame of the moving cart of Figure 10.1, the ball drops to the moving cart with a velocity that points vertically downward. In the cart's reference frame, the motion of the ball is free-fall motion, and a camera that moves along with the cart registers the motion shown in **Figure 10.2*a*.**

The picture is different, however, when observed from a stationary point located somewhere outside the cart—that is, from the Earth reference frame. Because the cart is moving to the right, the trajectory of the ball cannot be a straight vertical line in this reference frame. Figure 10.2*b* shows all the frames of the video clip of Figure 10.1 superimposed on one another. As you can see, in addition to its straight-downward motion relative to the cart, the ball is displaced horizontally from one frame to the next. Note that in spite of the rightward motion of the cart, the distance between ball and pole does not change. This constant distance is precisely what gives the illusion that the ball falls straight down! Your eyes tend to move along with the cart, and

Figure 10.1 A ball dropped from a pole attached to a cart moving at constant velocity falls straight down *relative to the cart*.



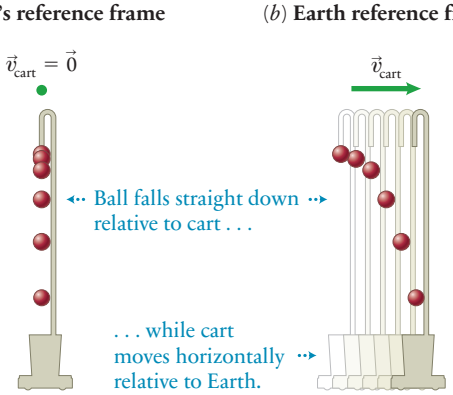


Figure 10.2 Motion of the ball of Figure 10.1 as recorded by a camera that is (*a*) moving along with the cart and (*b*) stationary.

CONCEPTS

so you register only the vertical motion of the ball relative to the cart. The frames of the video clip, however, show that the horizontal displacement of the ball is identical to that of the cart: If the x component of the displacement of the cart is Δx from one frame to the next, then the x component of the displacement of the ball must also be Δx. So, we see that *straight* is a relative term, one that depends on the reference frame.

The analysis in Figure 10.2 tells us that the motion of the ball in the Earth reference frame can be broken down into two parts: free fall in the vertical direction (called the *vertical component* of the motion) and motion at constant velocity in the horizontal direction (the *horizontal component* of the motion). You already know how to treat each of these motions separately. All that is left to do, therefore, is to develop a way to describe both motions at the same time.

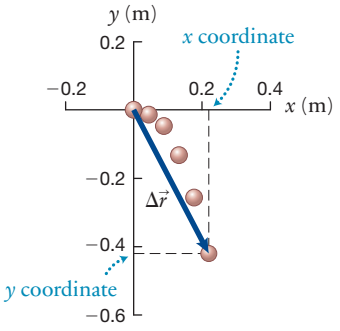
10.1 (*a*) In Figure 10.2, what is the ball's velocity the instant before it is released? (*b*) Is the ball's speed in the reference frame of the cart greater than, equal to, or smaller than its speed in the Earth reference frame?

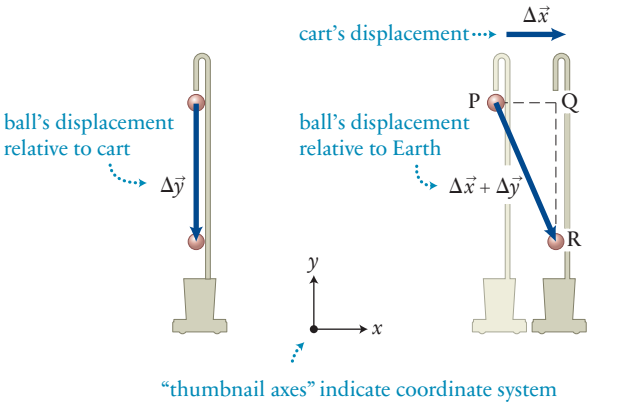
10.2 Vectors in a plane

To describe the motion of the ball in Figure 10.1, we need to generalize our definition of vectors. First of all, we need not one but two reference axes—one for each component of the motion. **Figure 10.3** shows one possible choice for a set of perpendicular reference axes. To distinguish the two axes, we label the horizontal one x and the vertical one y. The origins of both axes coincide with the point at which the ball is released.

To specify the position of the ball in each frame, we need two coordinates: an x *coordinate* to specify position along the x axis and a y *coordinate* to specify position along the y axis. For example, in the coordinate system shown in Figure 10.3, the position of the ball in frame 6 of Figure 10.1 is specified by the coordinates $x = +0.22$ m, $y = -0.42$ m. These coordinates also determine the position vector of the ball (see Section 2.6), which points from the origin to the position of the ball, as shown in Figure 10.3.

Figure 10.3 Position vector for the ball in frame 6 of Figure 10.1, using reference axes in the Earth reference frame.





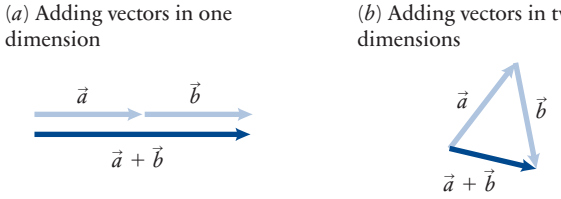


Figure 10.4 Displacement of the ball of Figure 10.1 in the reference frames of the cart and Earth.

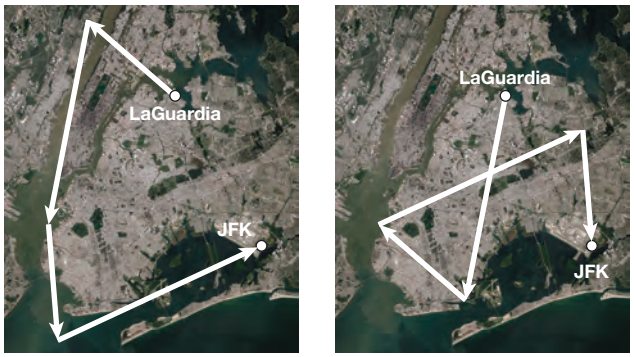
Unlike vectors in one dimension (describing motion along a straight line), vectors in two dimensions (describing motion in a plane) do not necessarily point along the axes. Consequently, we need to reexamine the rules for vector addition and subtraction. We'll do this by looking at the vector that represents the ball's displacement between frames 2 and 6 in Figure 10.1. **Figure 10.4*a*** shows the ball's displacement in the reference frame of the moving cart. This vector is labeled $\Delta\vec{y}$ to reflect the fact that it is parallel to the y axis. Figure 10.4*b* shows the corresponding view in the Earth reference frame. The *cart's* displacement is labeled $\Delta\vec{x}$ because it is parallel to the x axis. The *ball's* displacement, however, now points diagonally from the ball's initial position P to its final position R. Note that the ball can also go from P to R by two successive displacements: first from P to Q and then from Q to R. Even if the ball follows this path, though, its displacement is still given by the vector pointing from P to R. In other words, the ball's displacement in the Earth reference frame is the *vector sum* of the horizontal displacement $\Delta\vec{x}$ and the vertical displacement $\Delta\vec{y}$.

As with vectors along a straight line (one dimension), the vector sum of two vectors in a plane (two dimensions) is obtained by placing the tail of the second vector at the head of the first vector. There is, however, one important difference between one-dimensional and two-dimensional vector addition (**Figure 10.5**). In one

Figure 10.5 Vector addition in one and two dimensions.

CONCEPTS

Figure 10.6 The order in which vectors are added does not affect the final answer. These two imaginary flights starting at LaGuardia airport consist of the same vectors in different orders; both end up at the same destination of John F. Kennedy airport.



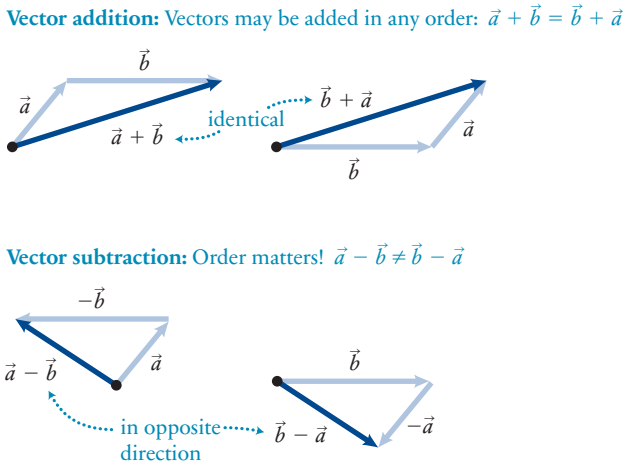


Figure 10.7 Vector addition and subtraction in two dimensions.

dimension, the sum of two vectors of equal length is either zero (when the vectors point in opposite directions) or a vector twice as long as each original vector (when they point in the same direction). In two dimensions, the length of the vector sum depends on the angle between the vectors being added. As Figure 10.5*b* shows, the length of the sum of two vectors can be smaller than the length of either original vector. When two or more vectors in a plane are added, the order in which the vectors are added is immaterial, as **Figure 10.6** shows.

The procedure for subtracting vectors in a plane is identical to that for subtraction in one dimension (**Figure 10.7**):

> **To subtract a vector $\vec{b}$ from a vector $\vec{a}$, reverse the direction of $\vec{b}$ and then add the reversed $\vec{b}$ to $\vec{a}$.**

As in one dimension, the vector $\vec{a} - \vec{b}$ points from the tail of vector $\vec{a}$ to the tip of vector $-\vec{b}$. Note that vector addition is commutative but vector subtraction is not: $\vec{a} + \vec{b} = \vec{b} + \vec{a}$ but $\vec{a} - \vec{b} \neq \vec{b} - \vec{a}$.

We can use the principles of vector addition to develop an important procedure: the decomposition of a vector into components. Just as we can add any two vectors to form a new vector, we can decompose (break up) any vector into two component vectors. For example, any vector $\vec{A}$ can be decomposed into **component vectors** $\vec{A}_x$ and $\vec{A}_y$ along the axes of some conveniently chosen set of mutually perpendicular axes, called a **rectangular coordinate system** (also called a *Cartesian coordinate system*).*

The procedure for decomposing a vector is shown in **Figure 10.8**. Note that if you add the resulting component vectors, you recover the original vector. When you decompose a vector, it is important to cross out the original vector so that you do not take both the original vector and the component vectors into account in any subsequent analysis.

*There is no formal requirement that the axes of the coordinate system be perpendicular to each other. Any set of two intersecting axes allows you to decompose and therefore uniquely specify all possible vectors in a plane. Calculations are considerably simpler, however, with axes that are perpendicular to each other.

Figure 10.8 Procedure for decomposing a vector using a set of mutually perpendicular axes.

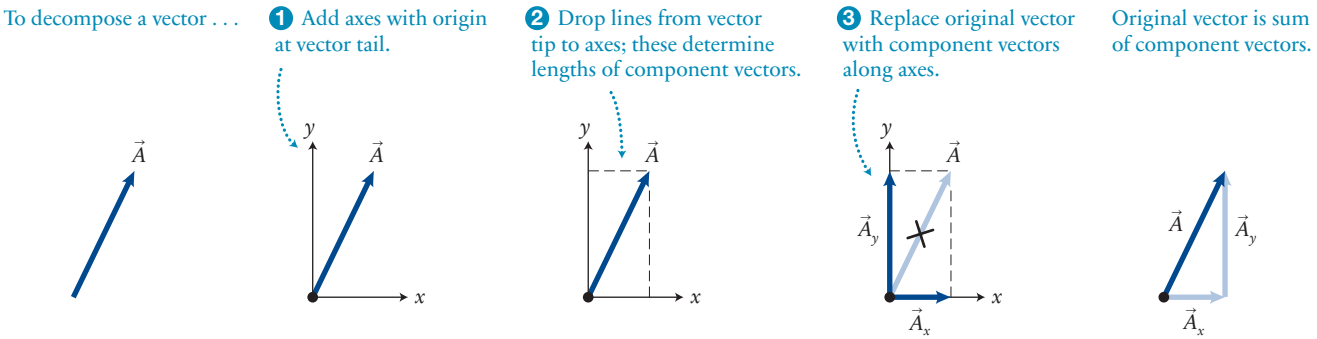

Figure 10.9 Decomposition of a vector $\vec{A}$ in three coordinate systems. In each coordinate system the component vectors $\vec{A}_x$ and $\vec{A}_y$ completely specify the position of point P relative to the origin. Which coordinate system is most convenient depends on the problem at hand.

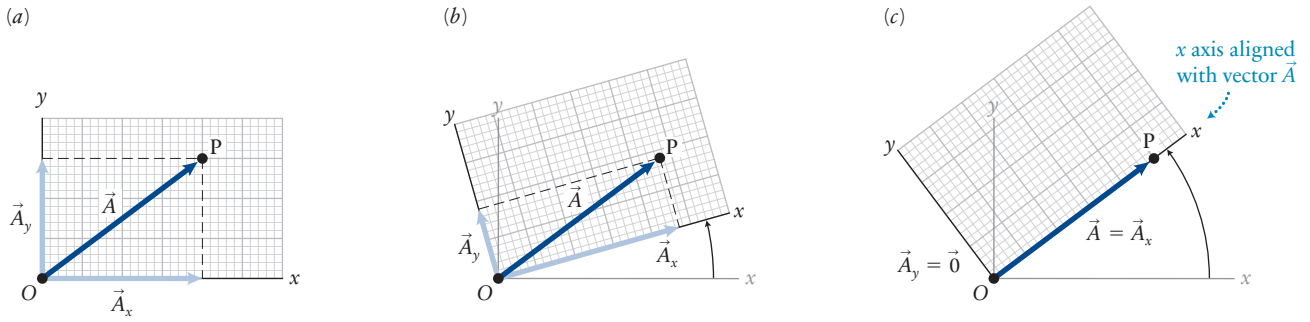

Figure 10.9 shows the decomposition of a vector $\vec{A}$ in three coordinate systems. In each coordinate system the component vectors $\vec{A}_x$ and $\vec{A}_y$ completely specify the position of point P relative to the origin O. In Figure 10.9*c* the coordinate system is such that the vector $\vec{A}$ lines up with the x axis. Now the component vector along the x axis is $\vec{A}$ and the component vector along the y axis is the zero vector. Which choice of coordinate system works best depends on the problem at hand (more on this later).

EXERCISE 10.1 Decompositions

If each major grid unit in Figure 10.9 corresponds to 1 m, specify the location of point P in terms of its x and y coordinates in each of the three coordinate systems.

SOLUTION (*a*) The vertical line dropped from P intercepts the x axis 4 grid units to the right of the y axis, so $x = +4.0$ m. The horizontal line dropped from P gives $y = +3.0$ m. The location of point P is thus given by $(x, y) = (+4.0\text{ m}, +3.0\text{ m})$. ✔

(*b*) $(x, y) = (+4.7\text{ m}, +1.8\text{ m})$. ✔

(*c*) $(x, y) = (+5.0\text{ m}, 0)$. ✔

CONCEPTS

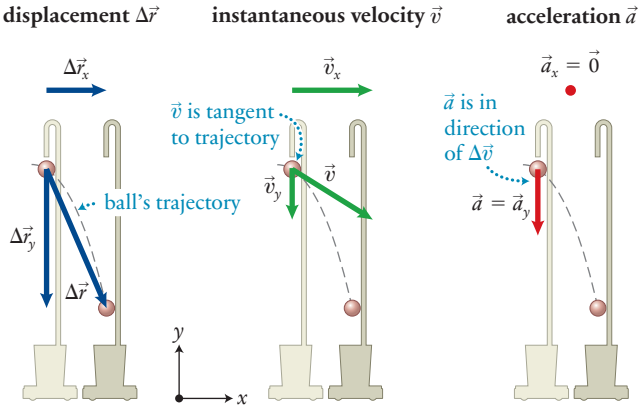
All the vector quantities we have encountered so far obey the rules for addition and subtraction outlined above, and all can be decomposed into component vectors. There is one significant difference, however, between the way vectors are treated in one-dimensional motion and the way they are treated in two-dimensional motion. As we saw in Section 2.8, the displacement and velocity of an object that moves along a straight line point in the same direction. Section 3.1 taught you that if the object speeds up, the acceleration also points in the same direction as the displacement, and if the object slows down, the acceleration points in the direction opposite that of the displacement and velocity. For motion in a plane, the relationship between the directions of these vectors is more complicated.

The displacement, instantaneous velocity, and acceleration of the ball in Figure 10.1 are shown in **Figure 10.10**. Because the ball's average velocity is its displacement divided by the time interval during which this displacement takes place, the average velocity (not shown in Figure 10.10) points in the same direction as the displacement. The ball's instantaneous velocity is the average velocity evaluated over infinitesimally small time intervals, and so if the object does not move in a straight line, the instantaneous velocity does not necessarily point in the same direction as the displacement. In Figure 10.10, for instance, $\Delta\vec{r}$ points from the initial to the final position over a certain time interval, while $\vec{v}$ is tangent to the trajectory—that is, in the instantaneous direction of travel.

Let us next consider the acceleration. By definition, the ball's acceleration points in the direction of the change in velocity. Because the horizontal component of the ball's velocity is equal to the velocity of the cart and so is constant, there is no acceleration in the horizontal direction. Only the vertical component of the ball's velocity changes, and so the ball's acceleration points downward rather than in the direction of $\vec{v}$. If you recall the relationship between acceleration and force ($\sum\vec{F} = m\vec{a}$), this makes sense: The ball's acceleration is caused by the downward force of gravity exerted by Earth on the ball. Therefore both the force and the acceleration point straight down.

What does it mean when the instantaneous velocity and acceleration of an object point in different directions?

Figure 10.10 Displacement, instantaneous velocity, and acceleration for the freely falling ball of Figure 10.1.



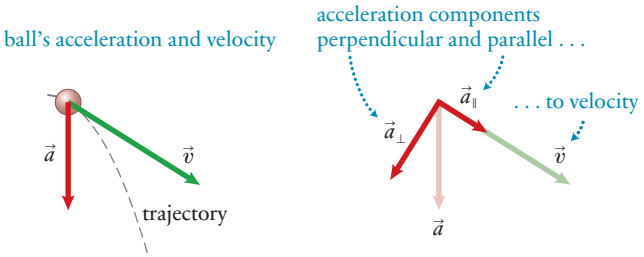


Figure 10.11 Velocity and acceleration vectors of the falling ball in frame 2 of Figure 10.1. Decomposition of $\vec{A}$ into component vectors parallel and perpendicular to $\vec{v}$.

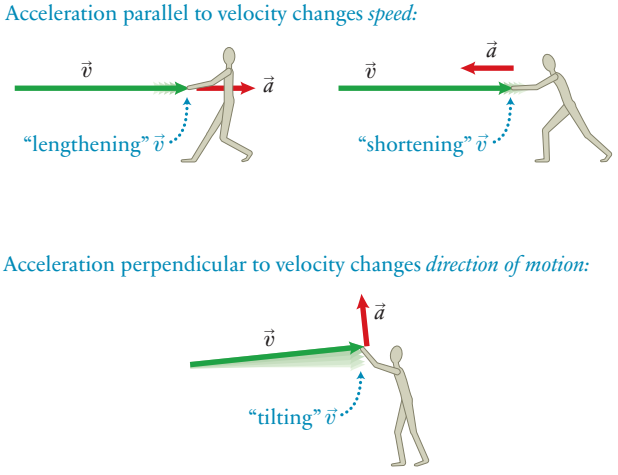
To answer this question, I must decompose the acceleration into two components: one parallel to the instantaneous velocity and one perpendicular to it (**Figure 10.11**). The parallel component causes the length of the instantaneous velocity—in other words, the ball's *speed*—to change. Just as for one-dimensional motion, the speed increases when the parallel component of the acceleration points in the same direction as the instantaneous velocity (as is the case with our ball-and-cart example) and decreases when they point in opposite directions. The perpendicular component of the acceleration causes the *direction* of the instantaneous velocity to change, which in our particular case of the ball and cart means that the ball does not move in a straight horizontal line the way the cart does. Instead, the ball's instantaneous velocity in any given frame of the video clip points more toward the ground than does its counterpart in the preceding frame. (In short, the ball curves downward.) In summary:

> **In two-dimensional motion, the component of the acceleration parallel to the instantaneous velocity changes the speed; the component of the acceleration perpendicular to the instantaneous velocity changes the direction of the instantaneous velocity but not its magnitude.**

These ideas are illustrated in **Figure 10.12**.

Figure 10.12 How the parallel and perpendicular components of acceleration affect velocity.



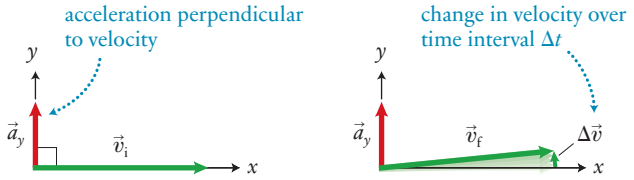


Figure 10.13 Change in velocity caused by a perpendicular acceleration.

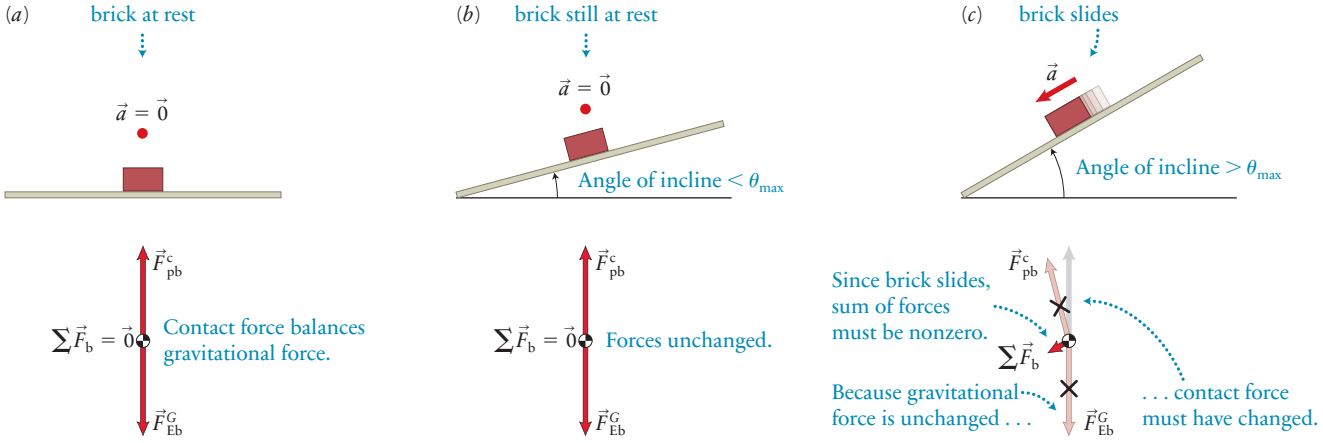
If you wonder how it can be that the perpendicular component changes *only* the direction of the velocity and does not affect its magnitude, examine **Figure 10.13**. An object initially moving in the positive x direction is given an acceleration in the positive y direction. Because of this acceleration, over a small but finite time interval Δt the object's initial velocity $\vec{v}_i$ gains a small component $\Delta\vec{v}$ in the y direction. The final velocity $\vec{v}_f = \vec{v}_i + \Delta\vec{v}$ therefore no longer points along the x axis—as we concluded before, $\vec{a}_y$, being perpendicular to $\vec{v}_i$, changes the direction of $\vec{v}_i$. Why then doesn't it also change the magnitude? The Pythagorean theorem tells us that the magnitude of $\vec{v}_f$ must be greater than that of $\vec{v}_i$, a result that appears to contradict what I just said about a perpendicular acceleration not affecting the magnitude of a horizontal velocity. The resolution of this contradiction lies in realizing that, as the direction of $\vec{v}$ changes, so does the angle between $\vec{v}$ and $\vec{a}_y$: The acceleration, because it is no longer exactly perpendicular to the velocity, now has a small component parallel to the velocity, and it is this component of the acceleration that causes the change in the magnitude of $\vec{v}$. We must therefore restrict our analysis to an infinitesimally small time interval. With this restriction, we can ignore the change in the magnitude of the velocity caused by $\Delta\vec{v}$: $v_i \approx v_f$.

CONCEPTS



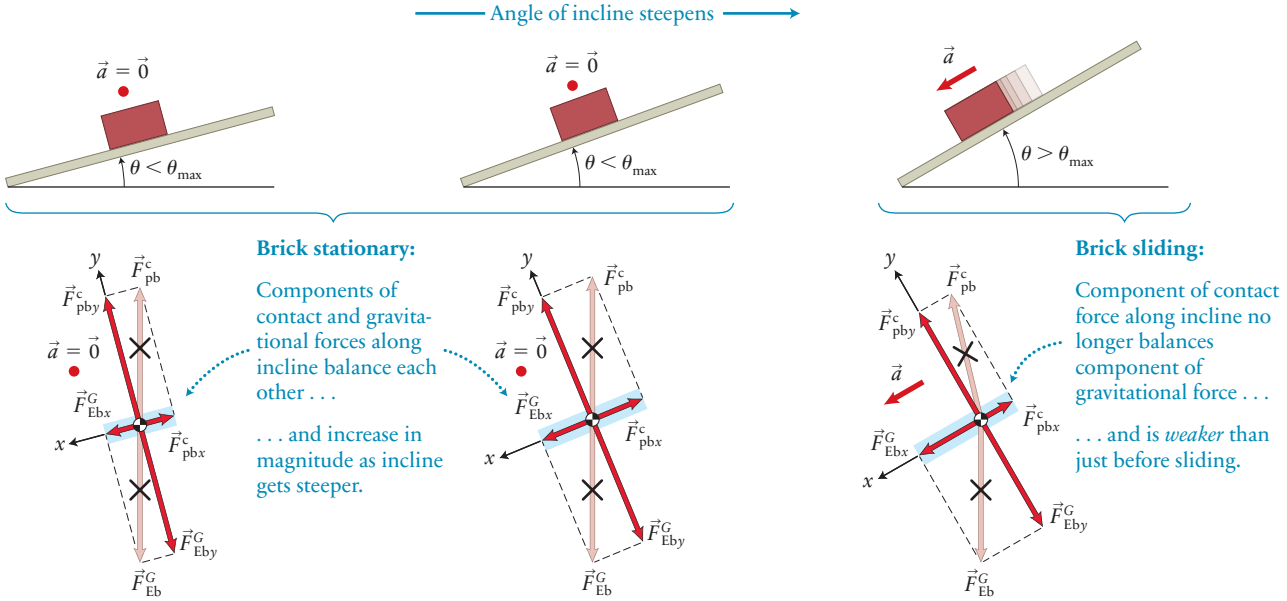
10.2 In Figure 10.10, the ball's instantaneous velocity $\vec{v}$ does not point in the same direction as the displacement $\Delta\vec{r}$ (it points *above* the final position of the ball). Why?

10.3 Decomposition of forces

Now that you know how to decompose vectors into components, let us see how this technique works with forces. Consider, for example, putting a brick on a horizontal plank and then slowly tilting the plank, as illustrated in **Figure 10.14**. Initially, the brick remains at rest, but when the angle of incline θ exceeds some maximum value θ_{max}, the brick suddenly slides downward. The angle of incline at which an object on an inclined surface begins to slide depends on the materials out of which the surface and the object are made and on their smoothness. It is also strongly affected by the presence of dirt or lubricants.

When the plank of Figure 10.14 is horizontal, the forces exerted on the brick are a downward gravitational

Figure 10.14 The forces exerted on a brick as you raise one end of the plank on which it rests.



force exerted by Earth and an upward contact force of equal magnitude exerted by the plank, as illustrated in the free-body diagram in Figure 10.14*a*. As long as the brick stays at rest, raising one end of the plank doesn't change the free-body diagram: The force of gravity on the brick does not depend on the inclination of the plank, and because the brick is still at rest we know that the force exerted by the plank must still be upward and equal in magnitude to the force of gravity, as shown in Figure 10.14*b*. When the angle of incline exceeds θ_{max} the situation changes, however. At that point, the contact force provided by the plank is no longer able to balance the downward force of gravity, and the brick accelerates down the incline. Although it is not immediately clear how to draw the free-body diagram, we know that the vector sum of the forces exerted on the brick must point in the same direction as the brick's acceleration (Figure 10.14*c*).

Because the brick is constrained to move along the surface of the plank, its acceleration must always be parallel to the plank, as shown in Figure 10.14*c*. For this reason, it makes sense to analyze the forces in terms of components parallel and perpendicular to the plank, by pointing the x axis along the surface that constrains the motion, as shown in **Figure 10.15**. The force components perpendicular to the surface are called **normal components;** those parallel to the surface are called **tangential components.** Because the brick's acceleration must be parallel to the plank, the normal component vectors $\vec{F}^c_{pby}$ and $\vec{F}^G_{Eby}$ must always be equal in magnitude—whether the brick is at rest or sliding. (If these two forces were not of equal magnitude, the brick would accelerate in the direction perpendicular to the plank, and we know this doesn't happen.)

The tangential component vectors $\vec{F}^c_{pbx}$ and $\vec{F}^G_{Ebx}$, on the other hand, are equal in magnitude only when

CONCEPTS

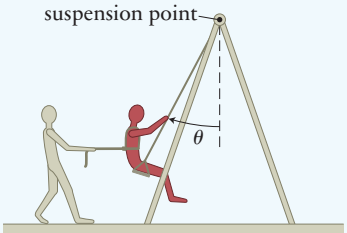
Figure 10.15 Free-body diagrams for a brick on a plank at different angles of inclination.

the brick is not accelerating down the incline. Note in Figure 10.15 that as the angle of incline is increased, the magnitude of the tangential component vector $\vec{F}^G_{\text{Eb}x}$ of the force of gravity increases. To prevent the brick from sliding down, the magnitude of the tangential component vector $\vec{F}^c_{\text{pb}x}$ of the contact force exerted by the plank on the brick must therefore also increase. When the angle of incline exceeds $\theta_{\max}$, the plank is no longer able to provide the sideways support necessary to hold the brick in place. The tangential component vectors of the forces no longer add up to zero, and the vector sum of the forces exerted on the brick is directed down the plank, as shown in Figure 10.14*c*.

10.3 A suitcase being loaded into an airplane moves at constant velocity on an inclined conveyor belt. Draw a free-body diagram for the suitcase as it moves up along with the belt. Show the normal and tangential components of the forces exerted on the suitcase.

Let us now return to a question raised in Section 10.2: What set of axes should you choose in a given problem? The example of the brick sliding down the inclined plank suggests an answer:

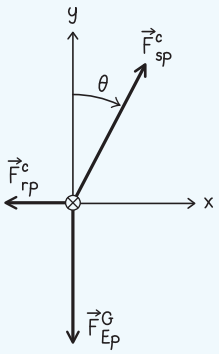
If possible, choose a coordinate system such that one of the axes lies along the direction of the acceleration of the object under consideration.



This choice of coordinate system allows you to break the problem neatly into two parts because only force components along the direction of acceleration can contribute to the motion.

When the acceleration of the object being considered is zero, choose your axes to coincide with the directions of as many forces as possible because no decomposition is necessary for any force that lies along an axis.

EXAMPLE 10.2 Pulling a friend on a swing



Using a rope, you pull a friend sitting on a swing (**Figure 10.16**). (*a*) As you increase the angle θ, does the magnitude of the force $\vec{F}^c_{\text{rp}}$ required to hold your friend in place increase or decrease? (*b*) Is the magnitude of that force larger than, equal to, or smaller than the magnitude of the gravitational force $\vec{F}^G_{\text{Ep}}$ exerted by Earth on your friend? (Consider the situation for both small and large values of θ.) (*c*) Is the magnitude of the force $\vec{F}^c_{\text{sp}}$ exerted by the swing on your friend larger than, equal to, or smaller than F^G_{Ep}?

Figure 10.16 Example 10.2.

1 GETTING STARTED I begin by drawing a free-body diagram of your friend (**Figure 10.17**). Three forces are exerted on him: $\vec{F}^G_{\text{Ep}}$, the force of gravity directed vertically downward, the horizontal force $\vec{F}^c_{\text{rp}}$ exerted by the rope, and a force $\vec{F}^c_{\text{sp}}$ exerted by the swing seat. This latter force $\vec{F}^c_{\text{sp}}$ is exerted by the suspension point via the chains of the swing and is thus directed along the chains. I therefore choose a horizontal x axis and a vertical y axis, so that two of the three forces lie along axes. Because your friend's acceleration is zero, the vector sum of the forces must be zero.

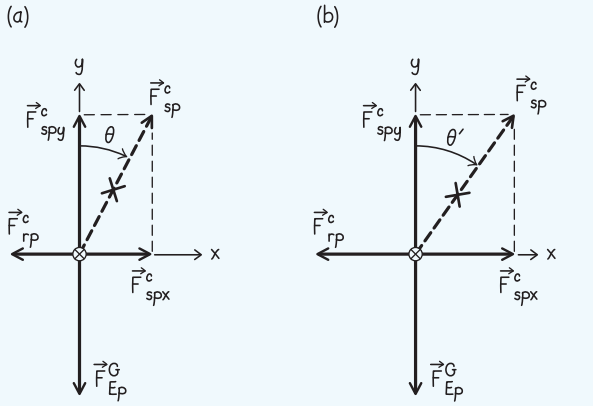


Figure 10.17

2 DEVISE PLAN Because your friend is at rest, the vectors along the two axes must add up to zero. The best way to see how the magnitude of the force $\vec{F}^c_{\text{rp}}$ exerted by the rope must change as θ is increased is to draw free-body diagrams showing different values of θ. To answer parts *b* and *c*, I can compare the various forces in my free-body diagrams.

3 EXECUTE PLAN (*a*) I begin by decomposing $\vec{F}^c_{\text{sp}}$ into x and y components (**Figure 10.18*a***). Because the forces must add to zero along both axes, I conclude from my diagram that $\vec{F}^c_{\text{sp}y}$ must be equal in magnitude to $\vec{F}^G_{\text{Ep}}$, the downward force of gravity. Likewise, $\vec{F}^c_{\text{sp}x}$ must be equal in magnitude to $\vec{F}^c_{\text{rp}}$, the horizontal force the rope exerts on your friend. Next, I draw a second free-body diagram for a larger angle θ (Figure 10.18*b*). As θ increases, $\vec{F}^c_{\text{sp}y}$ must remain equal in magnitude to $\vec{F}^G_{\text{Ep}}$ (otherwise your friend would accelerate vertically). As Figure 10.18*b* shows, increasing θ while keeping $\vec{F}^c_{\text{sp}y}$ constant requires the magnitude of $\vec{F}^c_{\text{sp}x}$ to increase. Because your friend is at rest, the forces in the horizontal direction must add up to zero and so $F^c_{\text{rp}} = |F^c_{\text{sp}x}|$. So if the magnitude of $\vec{F}^c_{\text{sp}x}$ increases, the magnitude of $\vec{F}^c_{\text{rp}}$ must increase, too. ✔

Figure 10.18

(Continued)

CONCEPTS

(b) From Figure 10.18 I see that $\tan\theta = |F^c_{spx}|/|F^c_{spy}|$. For $\theta < 45°$, $\tan\theta < 1$, and so $|F^c_{spx}| < |F^c_{spy}|$. Because $|F^c_{spy}| = F^G_{Ep}$ and $|F^c_{spx}| = F^c_{rp}$, I discover that for $\theta < 45°$, $F^c_{rp} < F^G_{Ep}$. When $\theta > 45°$, $\tan\theta > 1$, and so $|F^c_{spx}| > |F^c_{spy}|$ and $F^c_{rp} > F^G_{Ep}$. ✔

(c) $|\vec{F}^c_{spy}| = F^G_{Ep}$ and $F^c_{sp} = \sqrt{(F^c_{spx})^2 + (F^c_{spy})^2}$. Therefore, F^c_{sp} must always be larger than F^G_{Ep} when $\theta \neq 0$. ✔

4 EVALUATE RESULT I know from experience that you have to pull harder to move a swing farther from its equilibrium position, and so my answer to part a makes sense. With regard to part b, when the swing is at rest at 45°, the forces $\vec{F}^c_{rp}$ and $\vec{F}^G_{Ep}$ on your friend make the same angle with the force $\vec{F}^c_{sp}$, and so $\vec{F}^c_{rp}$ and $\vec{F}^G_{Ep}$ should be equal in magnitude. The force of gravity is independent of the angle, but the force exerted by the rope increases with increasing angle, and so it makes sense that for angles larger than 45°, $\vec{F}^c_{rp}$ is larger than $\vec{F}^G_{Ep}$. In part c, because the vertical component of the force $\vec{F}^c_{sp}$ exerted by the seat on your friend always has to be equal to the force of gravity, adding a horizontal component makes $\vec{F}^c_{sp}$ larger than $\vec{F}^G_{Ep}$, as I found.

10.4 You decide to move a heavy file cabinet by sliding it across the floor. You push against the cabinet, but it doesn't budge. Draw a free-body diagram for it.

10.4 Friction

The force that opposes your push on the file cabinet in Checkpoint 10.4—the tangential component of the contact force exerted by the floor on the cabinet—has to do with friction. If the floor were very slick or if the cabinet had wheels, there would be little friction and your push would easily move the cabinet. Instead, you have to lean against it with all your strength until, with a jerk, it suddenly begins to slide. Once you get the cabinet moving, you must keep pushing to keep it in motion. If you stop pushing, friction stops the motion.

10.5 (a) Suppose you push the file cabinet just enough to keep it moving at constant speed. Draw a free-body diagram for the cabinet while it slides at constant speed. (b) Suddenly you stop pushing. Draw a free-body diagram for the file cabinet at this instant.

Don't skip Checkpoint 10.5! It will be harder to understand the rest of this section if you haven't thought about these situations.

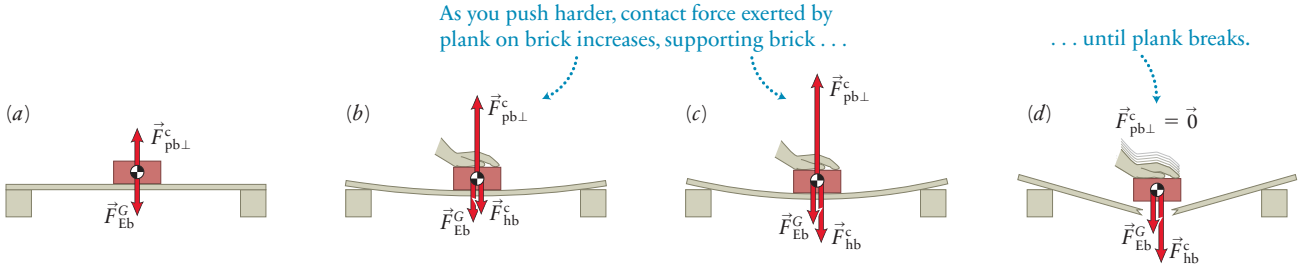
Even though the normal and tangential components of the contact force exerted by the floor on the cabinet belong to the same interaction, they behave differently and are usually treated as two separate forces: the normal component being called the **normal force** and the tangential component being called the **force of friction.**

To understand the difference between normal and frictional forces, consider a brick on a horizontal wooden plank supported at both ends (**Figure 10.19*a***). Because the brick is at rest, the normal force $\vec{F}^c_{pb\perp}$ exerted by the plank on it is equal in magnitude to the gravitational force exerted on it. Now imagine using your hand to push down on the brick with a force $\vec{F}^c_{hb}$. Your downward push increases the total downward force exerted on the brick, and, like a spring under compression, the plank bends until the normal force it exerts on the brick balances the combined downward forces exerted by your hand and by Earth on the brick (Figure 10.19b). As you push down harder, the plank bends more, and the normal force continues to increase (Figure 10.19c) until you exceed the plank's capacity to provide support and it snaps, at which point the normal force suddenly disappears (Figure 10.19d). So, normal forces take on whatever value is required to prevent whatever is pushing down on a surface from moving through that surface—up to the breaking point of the supporting material.

Next imagine that instead of pushing down on the brick of Figure 10.19a, you gently push it to the right, as in **Figure 10.20**. As long as you don't push hard, the brick remains at rest. This tells you that the horizontal forces exerted on the brick add to zero, and so the plank must be exerting on the brick a horizontal frictional force that is equal in magnitude to your push but in the opposite direction. This horizontal force is caused by microscopic bonds between the surfaces in contact. Whenever two objects are placed in contact, such bonds form at the extremities of microscopic bumps on the surfaces of the objects. When you try to slide the surfaces past each other, these tiny bonds prevent sideways motion. As you push the brick to the right, the bumps resist bending and, like microscopic springs, each bump exerts a force to the left. The net effect of all these microscopic forces

CONCEPTS

Figure 10.19 A demonstration of the normal force.



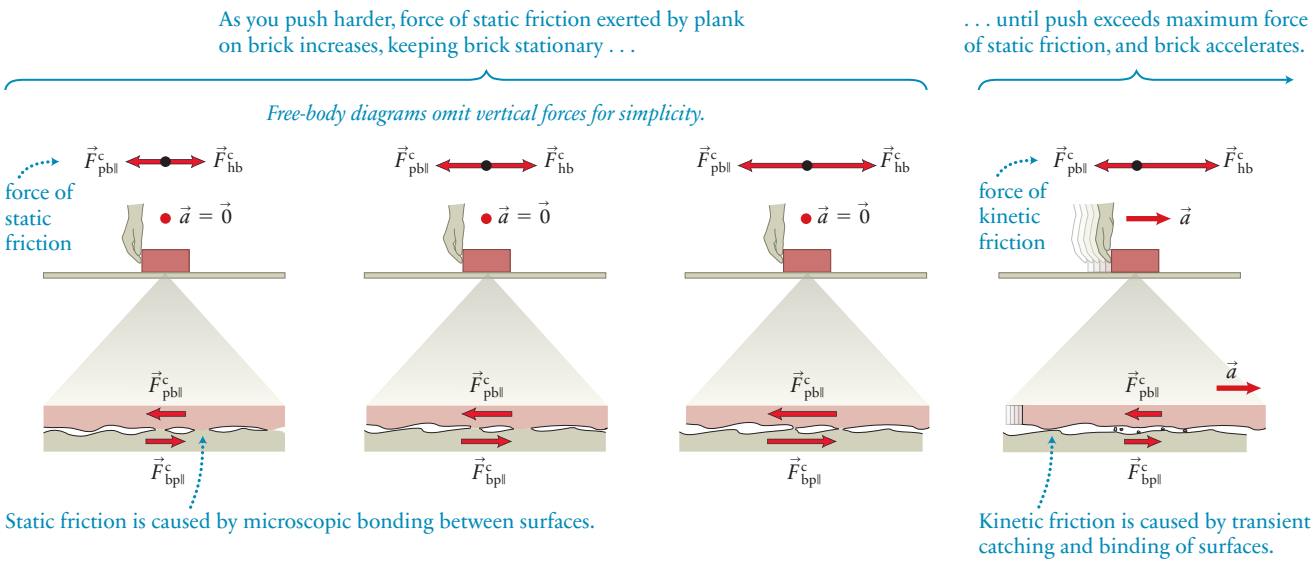


Figure 10.20 The microscopic basis for forces of static and kinetic friction (b = brick, p = plank, h = hand).

is to hold the brick in place. As you increase the force of your push, the bumps resist bending more and the tangential component of the contact force grows. This friction exerted by surfaces that are not moving relative to each other is called **static friction.**

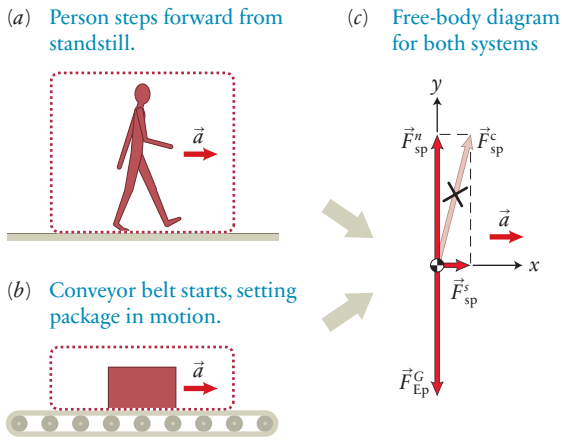
The tiny bonds cannot withstand large forces, however, and as you continue to increase your sideways push on the brick, the bonds get ripped apart, the tangential force they provide can no longer resist the push, and the brick starts to slide. The surface of the brick is no longer at rest relative to the surface on which the brick is resting—the two surfaces are said to *slip*.

Once the brick slips, bumps on the surfaces plow into each other, continually forming and breaking microscopic bonds, and microscopic pieces chip off from the surface. This constant bumping, making and breaking of bonds, and chipping cause what is called **kinetic friction.** Even though kinetic friction causes slipping surfaces to wear and to heat up, it is not always undesirable: Kinetic friction makes it possible to slow down the moving wheels of a car or bicycle, to use an eraser, and to warm up your hands by rubbing them, just to name a few examples.

So, just as the normal force takes on whatever value is necessary to prevent motion on a surface, the force of static friction takes on whatever value is necessary to prevent two surfaces from slipping past each other. The main differences between normal forces and forces of static friction are: (1) The maximum value of the force of static friction is generally much smaller than the maximum value of the normal force (it is relatively easy to push the brick across the plank but nearly impossible to push it through the plank), and (2) once the maximum value of the normal force is reached, the normal force disappears, but once the maximum value of the force of static friction is reached, there still is a smaller but nonzero force of kinetic friction.

To distinguish more easily among the various components of the contact force exerted by surface 1 on surface 2, we shall when necessary replace the superscript c by n for the normal force ($\vec{F}^{c}_{12\perp}$ becomes $\vec{F}^{n}_{12}$), by s for the force of static friction, and by k for the force of kinetic friction ($\vec{F}^{c}_{12\parallel}$ becomes $\vec{F}^{s}_{12}$ or $\vec{F}^{k}_{12}$).

10.6 Which type of friction—static or kinetic—plays a role in (*a*) holding a pencil, (*b*) chalk making marks on a chalkboard, (*c*) skiing downhill, (*d*) polishing a metal surface, and (*e*) walking (without sliding) down an incline?



10.5 Work and friction

Like the normal force, the force of static friction is an elastic force: It causes no irreversible changes. The deformations that take place undo themselves when the force that caused them is removed. If you stop pushing on the file cabinet of Checkpoint 10.4 before it starts moving, for example, you will not scratch the floor. Kinetic friction, however, does cause damage, mainly because of the chipping mentioned earlier. Push the cabinet a short distance, no matter how carefully, and you will cause some damage, both to the bottom surface of the cabinet and to the floor surface. At best the damage is microscopic, but if you were to push the cabinet around the floor all day long, your landlady would probably not renew your lease. The heating and wear caused by kinetic friction turn coherent energy into incoherent energy. To sum up:

The force of kinetic friction is not an elastic force and so causes energy dissipation. The force of static friction is an elastic force and so causes no energy dissipation.

CONCEPTS

Figure 10.21 Two equivalent situations in which an object is accelerated by static friction.

In Section 9.4 I cautioned against choosing a system for which friction occurs at the boundary because you don't know how much of the dissipated energy ends up on each side of the boundary. Now you see that this caveat does not apply to static friction because static friction causes no energy dissipation.

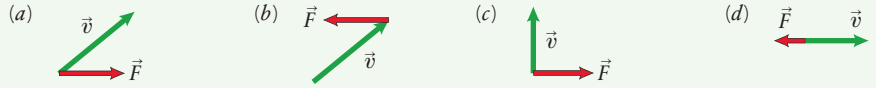
This brings us to the question of whether or not the force of static friction can do work on a system. After all, static friction does not involve any motion of the two surfaces relative to each other, and work requires a nonzero force displacement. To answer this question, consider the two situations shown in **Figure 10.21**: A person starts to walk and a package is set in motion by a conveyor belt. In both cases the system (the person in Figure 10.21*a* and the package in Figure 10.21*b*) gains kinetic energy. Where does that energy come from, and what is the role of static friction in each case?

Let us first look at Figure 10.21*a*. To begin walking, the person leans slightly forward and raises one foot, with her other foot pressing on the floor downward and backward. The floor surface then supplies an upward contact force $\vec{F}^c_{sp}$ that is tilted forward, as shown in Figure 10.21*c*. The force $\vec{F}^c_{ps}$ of the person pressing down on the surface and the force $\vec{F}^c_{sp}$ of the surface pushing up form an interaction pair. Because she is not accelerating in the vertical direction, the forces in that direction must add to zero, and so the normal component of the contact force exerted on the person—the normal force $\vec{F}^c_{sp}$—is equal in magnitude to the force of gravity exerted on her. The tangential component $\vec{F}^s_{sp}$ is what propels her forward. As long as the foot doesn't slip, this tangential component is due to static friction; the forward acceleration is then equal to the force of static friction divided by the person's inertia.

To determine whether or not the force of static friction exerted by the floor surface on the person does work on the person, we need to look at the force displacement. Because the force of static friction is applied at the foot, which does not move in any direction while it is on the floor surface, the force displacement is zero. The surface therefore does no work on the person. That makes sense because *she* supplies the energy required to accelerate, not the surface.

Next, look at Figure 10.21*b*. The free-body diagram for this situation is the same as that for the person. Two forces are exerted on the package: a downward force of gravity $\vec{F}^G_{Ep}$ and a contact force $\vec{F}^c_{sp}$ exerted by the surface of the conveyor belt. The normal component of the contact force is equal in magnitude to the force of gravity; the tangential component (the force of static friction) is what causes the package to accelerate. The point of application of the force of static friction moves along with the package, and so the force of static friction does work on the package. This, too, makes sense: The package has no way of internally generating any kinetic energy; it is the conveyor that must do this. So, like any other elastic contact force, the force of static friction *can* do work on a system, and it is perfectly all right to choose a system in which *static* friction occurs at the boundary. It's only kinetic friction that causes problems because this type of friction dissipates energy, generating thermal energy that is distributed on both sides of the surface.

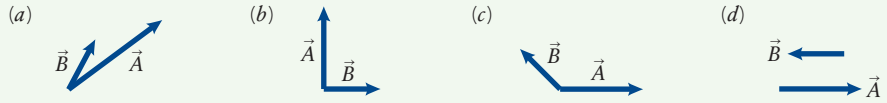
Figure 10.21 also dispels the often-heard myth that friction always *opposes* motion. In both cases shown in the figure, friction *causes* the motion. Without the forward pointing force of friction, neither the person nor the package would accelerate. Friction opposes the motion of two surfaces *relative to each other,* not motion per se. In Figure 10.21*a*, for instance, the person's rear foot would slip backward if there were no forward-pointing force of friction. The force of static friction prevents this slipping motion, and in doing so it pushes her forward.



10.7 Draw energy diagrams for the person and the package in Figure 10.21.

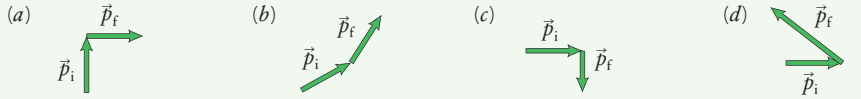
CONCEPTS

Self-quiz



1. In the diagrams in **Figure 10.22**, the velocity of an object is given along with the vector representing a force exerted on the object. For each case, determine whether the object's speed increases, decreases, or remains constant. Also determine whether the object's direction changes in the clockwise direction, changes in the counterclockwise direction, or doesn't change.

Figure 10.22

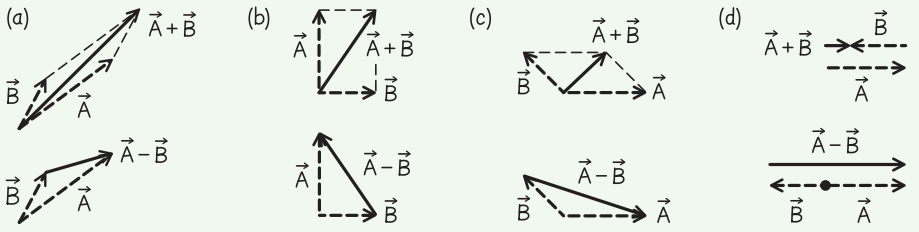


2. Draw the sum $\vec{A} + \vec{B}$ and the difference $\vec{A} - \vec{B}$ of each vector pair in **Figure 10.23**.

Figure 10.23

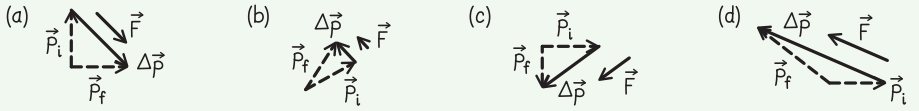
3. Each diagram in **Figure 10.24** indicates the momentum of an object before and after a single force is exerted on it. For each case determine the direction of the force.

Figure 10.24



4. While driving to school, you place your coffee cup on the dashboard. Which type of force of friction allows the cup to stay put on the dashboard when the car speeds up? Does this force do any work on the cup?

Answers



1. (*a*) $\vec{F}$ has component vectors parallel and perpendicular to $\vec{v}$. Because $\vec{F}_{\parallel}$ is in the same direction as $\vec{v}$, the speed increases. $\vec{F}_{\perp}$ tilts $\vec{v}$ clockwise from its current position. (*b*) Because the direction of $\vec{F}_{\parallel}$ is opposite the direction of $\vec{v}$, the speed decreases. $\vec{F}_{\perp}$ tilts $\vec{v}$ counterclockwise from its current position. (*c*) Because $\vec{F}_{\parallel} = 0$, the speed remains the same; $\vec{F}_{\perp}$ tilts $\vec{v}$ clockwise. (*d*) $\vec{F}_{\parallel}$ decreases the speed. $\vec{F}_{\perp} = 0$ and so the direction of $\vec{v}$ does not change.
2. The vector sum is equal to the diagonal of a parallelogram drawn using the two vectors placed tail to tail. The vector difference points from the tip of the second vector to the tip of the first vector (**Figure 10.25**).

Figure 10.25

3. In each case the force is parallel to $\Delta\vec{p} = \vec{p}_f - \vec{p}_i$ (**Figure 10.26**).

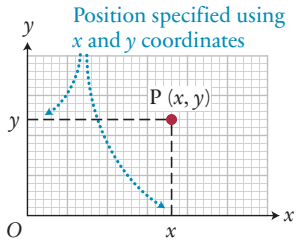


Figure 10.26

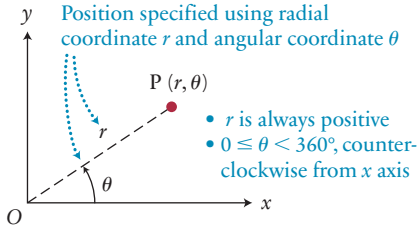
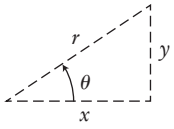


4. Because no sliding occurs, the force of friction must be static. Because the force displacement and the force point in the same direction when the car speeds up, this force does positive work on the cup.

Figure 10.27 Rectangular and polar coordinates.



(*a*) Rectangular coordinates

(*b*) Polar coordinates

(*c*) Relationship between the two

10.6 Vector algebra

In a rectangular coordinate system, the position of a point P is specified by the rectangular coordinates x and y (**Figure 10.27a**). Alternatively, we can specify a point using **polar coordinates** (Figure 10.27*b*). The *radial* coordinate r gives the distance from the origin to the point and is always positive. The *angular* coordinate θ specifies the angle between r and the x axis and is measured counterclockwise from the positive x axis ($0 \le \theta < 360°$). Any arbitrary point P is specified entirely by either (x, y) or (r, θ).

As can be seen from Figure 10.27*c*, the radial coordinate r is the hypotenuse of a right triangle with sides x and y, so

$$r = +\sqrt{x^2 + y^2}. \tag{10.1}$$

The plus sign in front of the square root indicates that r is never negative. Trigonometry tells us that $\tan\theta = y/x$, so

$$\theta = \tan^{-1}\left(\frac{y}{x}\right), \tag{10.2}$$

where the signs of x and y determine in which quadrant θ lies. Equations 10.1 and 10.2 allow us to determine polar coordinates from rectangular ones. Using trigonometry, we can also express rectangular coordinates in terms of polar coordinates:

$$\begin{aligned} x &= r\cos\theta \\ y &= r\sin\theta. \end{aligned} \tag{10.3}$$

EXERCISE 10.3 Polar point

If each major grid unit in Figure 10.27 corresponds to 1 m, specify the location of point P in polar coordinates.

SOLUTION I begin by reading off the rectangular coordinates: $x = +3.6$ m, $y = +2.4$ m. Then I can use Eqs. 10.1 and 10.2 to convert to polar coordinates:

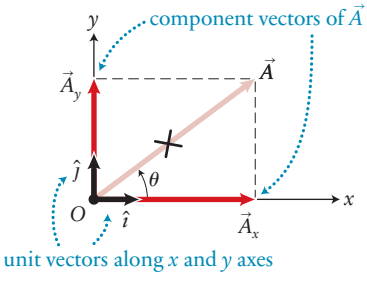
$$r = +\sqrt{x^2 + y^2} = +\sqrt{(3.6\text{ m})^2 + (2.4\text{ m})^2} = +4.3\text{ m}$$

and

$$\theta = \tan^{-1}\left(\frac{y}{x}\right) = \tan^{-1}\left(\frac{2.4\text{ m}}{3.6\text{ m}}\right) = 34°.$$

So, in polar coordinates point P is at $(r, \theta) = (4.3\text{ m}, 34°)$. ✔

In rectangular coordinates, the position vector of a point P is



$$\vec{r} \equiv x\,\hat{\imath} + y\,\hat{\jmath}, \tag{10.4}$$

where $\hat{\imath}$ and $\hat{\jmath}$ represent unit vectors along the x and y axes, respectively. The component vectors of $\vec{r}$ are $x\,\hat{\imath}$ and $y\,\hat{\jmath}$. More generally, the decomposition of an arbitrary vector $\vec{A}$ can be written as follows (**Figure 10.28**):

$$\vec{A} = \vec{A}_x + \vec{A}_y = A_x\hat{\imath} + A_y\hat{\jmath}, \tag{10.5}$$

where $\vec{A}_x$ and $\vec{A}_y$ are *component vectors* of $\vec{A}$; A_x and A_y are the x *and* y *components* of $\vec{A}$. Keep in mind that the x and y components, A_x and A_y, are signed numbers—these symbols do *not* represent the magnitudes of the

Figure 10.28 Decomposition of a general vector $\vec{A}$ into component vectors.

QUANTITATIVE TOOLS

component vectors $\vec{A}_x$ and $\vec{A}_y$. Whenever you see a subscript x or y (and later also z) on a symbol that does not have an arrow over it, the quantity represented by that symbol is a component of a vector and carries an algebraic sign.

Using the Pythagorean theorem, we can write the magnitude of $\vec{A}$ as

$$A \equiv |\vec{A}| = +\sqrt{A_x^2 + A_y^2}, \tag{10.6}$$

where the plus sign in front of the square root indicates that only the positive square root applies because magnitude is always a positive quantity. The angle of $\vec{A}$ with respect to the x axis is specified by

$$\tan\theta = \frac{A_y}{A_x}, \tag{10.7}$$

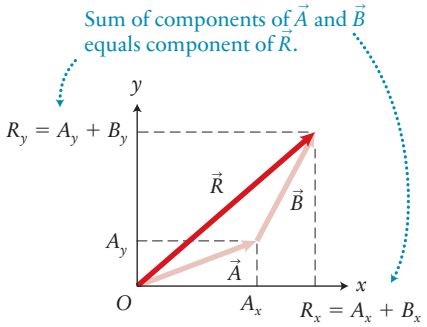
where the signs of A_x and A_y determine in which quadrant θ lies.

The decomposition of vectors is particularly useful when adding or subtracting them. As **Figure 10.29** shows, the x and y components of the vector sum $\vec{R}$ of two vectors $\vec{A}$ and $\vec{B}$ are equal to the sum of the corresponding components of $\vec{A}$ and $\vec{B}$:

$$\vec{R} = (A_x + B_x)\hat{\imath} + (A_y + B_y)\hat{\jmath} \tag{10.8}$$

$$\begin{aligned} R_x &= A_x + B_x \\ R_y &= A_y + B_y. \end{aligned} \tag{10.9}$$

Figure 10.29 Adding vectors by components.



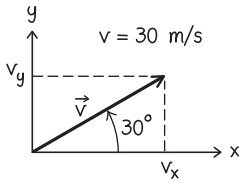


Figure 10.30 Example 10.4.

EXAMPLE 10.4 Speeding ball

A ball is thrown at an angle of 30° above the horizontal at a speed of 30 m/s. Write the ball's velocity in terms of rectangular unit vectors.

❶ **GETTING STARTED** I begin by making a sketch showing the velocity vector $\vec{v}$ and its decomposition in a rectangular coordinate system (**Figure 10.30**). I position the x axis along the horizontal in the direction of motion and the y axis along the vertical. I label the x and y components of the ball's velocity v_x and v_y, respectively.

❷ **DEVISE PLAN** Equation 10.5 tells me that the velocity vector can be written as $\vec{v} = v_x\hat{\imath} + v_y\hat{\jmath}$. To determine the x and y components, I apply trigonometry to the triangle made up by v, v_x, and v_y.

❸ **EXECUTE PLAN** From my sketch I see that $\cos\theta = v_x/v$ and $\sin\theta = v_y/v$, where $v = 30$ m/s and $\theta = 30°$. Therefore $v_x = v\cos\theta$ and $v_y = v\sin\theta$. Substituting the values given for v and θ, I calculate the rectangular components:

$$v_x = (30\text{ m/s})(\cos 30°) = (30\text{ m/s})(0.87) = +26\text{ m/s}$$

$$v_y = (30\text{ m/s})(\sin 30°) = (30\text{ m/s})(0.50) = +15\text{ m/s}.$$

The velocity in terms of unit vectors is thus

$$\vec{v} = v_x\hat{\imath} + v_y\hat{\jmath} = (+26\text{ m/s})\hat{\imath} + (+15\text{ m/s})\hat{\jmath}. \checkmark$$

❹ **EVALUATE RESULT** The x and y components are both positive, as I expect because I chose the direction of the axis in the direction that the ball is moving, and the magnitude of v_x is larger than that of v_y, as it should be for a launch angle that is smaller than 45°. I can quickly check my math by using Eq. 10.6 to calculate the magnitude of the velocity: $v = \sqrt{v_x^2 + v_y^2} = \sqrt{(26\text{ m/s})^2 + (15\text{ m/s})^2} = 30$ m/s, which is the speed at which the ball is launched.

10.8 You navigate a ship from a pier to a buoy 1500 m northeast of the pier. There you sail to a point 300 m south and 700 m east of the buoy. What is your distance from the pier at that point, if you do not move relative to the ship?

10.7 Projectile motion in two dimensions

We can now generalize the description of motion in a plane, starting with the position vector of an object:

$$\vec{r} = x\hat{\imath} + y\hat{\jmath}. \tag{10.10}$$

As in one dimension, the object's instantaneous velocity is

$$\vec{v} \equiv \frac{d\vec{r}}{dt} \equiv \lim_{\Delta t \to 0} \frac{\Delta \vec{r}}{\Delta t}. \tag{10.11}$$

Substituting Eq. 10.10 into Eq. 10.11, we obtain

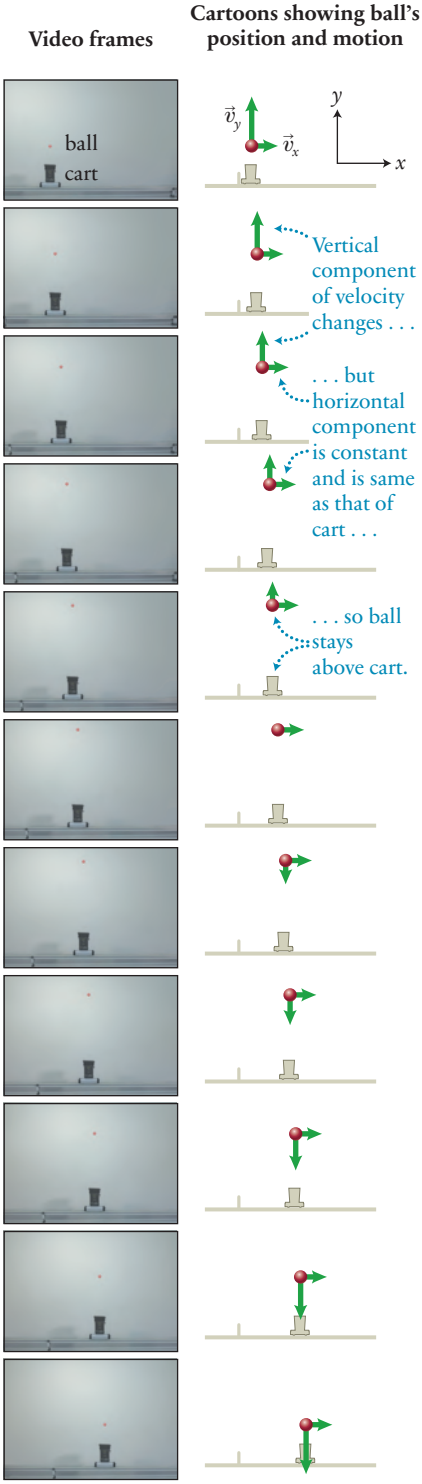
$$\vec{v} = \lim_{\Delta t \to 0} \frac{\Delta x}{\Delta t}\hat{\imath} + \lim_{\Delta t \to 0} \frac{\Delta y}{\Delta t}\hat{\jmath} = v_x\hat{\imath} + v_y\hat{\jmath}, \tag{10.12}$$

so that

$$v_x = \frac{dx}{dt} \quad \text{and} \quad v_y = \frac{dy}{dt}. \tag{10.13}$$

Likewise, the components of the instantaneous acceleration are

$$a_x = \frac{dv_x}{dt} = \frac{d^2x}{dt^2} \quad \text{and} \quad a_y = \frac{dv_y}{dt} = \frac{d^2y}{dt^2}. \tag{10.14}$$



Knowing how to decompose vectors into components allows us to separate motion in a plane into two one-dimensional problems. Consider the motion of a ball launched straight up from a cart moving at constant velocity (**Figure 10.31**). Like the ball dropped from the moving cart in Figure 10.1, the launched ball remains vertically above the cart throughout its trajectory and so falls back into the cart. In the reference frame of the cart, the ball's motion is identical to the one-dimensional projectile motion we studied in Section 3.3. In the Earth reference frame, though, the ball's instantaneous velocity has a component in the horizontal direction in addition to the component in the vertical direction. The resulting two-dimensional projectile motion in the Earth reference frame is the curved trajectory shown in **Figure 10.32**. (For this discussion, ignore air resistance.)

How do we obtain the ball's position at some arbitrary instant $t_f = t_i + \Delta t$? Let us begin by writing the initial condition for the ball's motion in the Earth reference frame at instant t_i. Because the ball's acceleration is always vertically downward, we choose a coordinate system that has a horizontal x axis and a vertical y axis. In the Earth reference frame, the ball's initial velocity is thus

$$\vec{v}_i = v_{x,i}\hat{\imath} + v_{y,i}\hat{\jmath}. \tag{10.15}$$

As viewed from the Earth reference frame, the ball's initial horizontal velocity is equal to the cart's constant velocity. The presence of the horizontal velocity in Eq. 10.15 tells us that, as viewed from the Earth reference

Figure 10.31 Ball launched vertically up from a cart moving at constant velocity in the horizontal direction.

QUANTITATIVE TOOLS

frame, the ball is launched not straight up but at an angle θ relative to the x axis given by

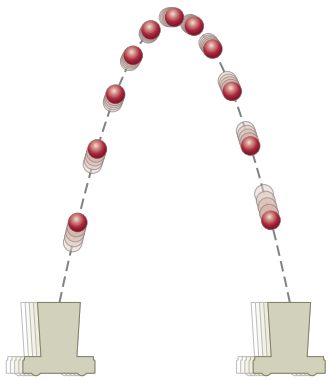
$$\tan\theta = \frac{v_{y,i}}{v_{x,i}}. \tag{10.16}$$

The ball's velocity in the horizontal direction is constant; in the vertical direction, the ball has a constant downward acceleration of magnitude $a_y = -g$. The x component of the ball's instantaneous velocity is not changing. We can obtain the y component at instant t_f from Eq. 3.4:

$$v_{x,f} = v_{x,i} \quad \text{(constant velocity)} \tag{10.17}$$

$$v_{y,f} = v_{y,i} - g\Delta t \quad \text{(constant acceleration)}. \tag{10.18}$$

We can now use the results we derived for one-dimensional projectile motion to determine the position of the ball at any instant. The ball's horizontal position at instant t_f is given by Eq. 2.19, $x_f = x_i + v_{x,i}\Delta t$. For the vertical position we use Eq. 3.8, $x_f = x_i + v_{x,i}\Delta t + \frac{1}{2}a_x(\Delta t)^2$, replacing x by y and then setting $a_y = -g$:



$$x_f = x_i + v_{x,i}\Delta t \quad \text{(constant velocity)} \tag{10.19}$$

$$y_f = y_i + v_{y,i}\Delta t - \tfrac{1}{2}g(\Delta t)^2 \quad \text{(constant acceleration)}. \tag{10.20}$$

These two equations completely determine the trajectory of a projectile launched with initial velocity $\vec{v}_i$ from point (x_i, y_i).

Equations 10.19 and 10.20 give us x_f and y_f as functions of Δt because $x \propto \Delta t$ and $y \propto (\Delta t)^2$. By eliminating Δt from these equations, we obtain a function $y(x)$ that depends quadratically on x and describes a parabola. Hence the trajectory of a projectile whose initial velocity is not vertical is a parabola.

Figure 10.32 Trajectory of the ball in Figure 10.31 as seen from the Earth reference frame.

EXAMPLE 10.5 Position of highest point

The ball of Figure 10.32 is launched from the origin of an xy coordinate system. Write expressions giving, at the top of its trajectory, the ball's rectangular coordinates in terms of the components of its initial speed v_i and the acceleration due to gravity g.

❶ **GETTING STARTED** Because the ball is launched from the origin, $x_i = 0$ and $y_i = 0$. As the ball moves upward, the vertical component of its velocity, v_y, is positive. After crossing its highest position, the ball moves downward, and so now v_y is negative. As the ball passes through its highest position, therefore, v_y reverses sign, so at that position $v_y = 0$.

❷ **DEVISE PLAN** Taking the highest position as my final position and then substituting $v_{y,f} = 0$ into Eq. 10.18, I can determine the time interval Δt_{top} it takes the ball to travel to this position. Once I know Δt_{top}, I can use Eqs. 10.19 and 10.20 to obtain the ball's coordinates at the top.

❸ **EXECUTE PLAN** Substituting $v_{y,f} = 0$ into Eq. 10.18, I get

$$0 = v_{y,i} - g\Delta t_{top}.$$

Solving for Δt_{top} then yields

$$\Delta t_{top} = \frac{v_{y,i}}{g}. \tag{1}$$

Using $x_i = 0$, $y_i = 0$ in Eqs. 10.19 and 10.20, I then calculate the location of the highest position:

$$x_{top} = 0 + v_{x,i}\left(\frac{v_{y,i}}{g}\right) = \frac{v_{x,i}v_{y,i}}{g}$$

and

$$y_{top} = 0 + v_{y,i}\left(\frac{v_{y,i}}{g}\right) - \tfrac{1}{2}g\left(\frac{v_{y,i}}{g}\right)^2$$

$$= \frac{v_{y,i}^2}{g} - \frac{1}{2}\frac{v_{y,i}^2}{g} = \frac{1}{2}\frac{v_{y,i}^2}{g}. \checkmark$$

❹ **EVALUATE RESULT** Because the ball moves at constant velocity in the horizontal direction, the x coordinate of the highest position is the horizontal velocity component $v_{x,i}$ multiplied by the time interval it takes to reach the top (given by Eq. 1). The y coordinate of the highest position does not depend on $v_{x,i}$ as I expect because the vertical and horizontal motions are independent of each other.

QUANTITATIVE TOOLS

EXAMPLE 10.6 Range of a projectile

How far from the launch position is the position at which the ball of Figure 10.32 is once again back in the cart? (This distance is called the *horizontal range* of the projectile.)

❶ **GETTING STARTED** As we saw in Example 3.6, the time interval taken by a projectile to return to its launch position from the top of the trajectory is equal to the time interval Δt_{top} it takes to travel from the launch position to the top. I can therefore use the Δt_{top} expression I found in Example 10.5 to solve this problem.

❷ **DEVISE PLAN** If the time interval it takes the ball to travel from its launch position to the top is Δt_{top}, then the time interval the ball is in the air is $2\Delta t_{top}$. Because the ball travels at constant velocity in the horizontal direction, I can use Eq. 10.19 to obtain the ball's range.

❸ **EXECUTE PLAN** From Example 10.5, I have $\Delta t_{top} = v_{y,i}/g$, and so the time interval spent in the air is $\Delta t_{flight} = 2v_{y,i}/g$. Substituting this value into Eq. 10.19 yields

$$x_f = 0 + v_{x,i}\left(\frac{2v_{y,i}}{g}\right) = \frac{2v_{x,i}v_{y,i}}{g}. \checkmark$$

❹ **EVALUATE RESULT** Because the trajectory is an inverted parabola, the top of the parabola lies midway between the two locations where the parabola intercepts the horizontal axis. So the location at which the parabola returns to the horizontal axis lies a horizontal distance twice as far from the origin as the horizontal distance at the top. In Example 10.5 I found that $x_{top} = v_{x,i}v_{y,i}/g$. The answer I get for the horizontal range is indeed twice this value.

10.9 Suppose a projectile's initial velocity is specified by the initial speed v_i and launch angle θ instead of by its rectangular components as in Eq. 10.15. (*a*) Using Eqs. 10.3, write expressions for the projectile's maximum height and horizontal range in terms of v_i and θ. (*b*) What angle θ gives the greatest value of y_{max}? (*c*) Of x_{max}?

10.8 Collisions and momentum in two dimensions

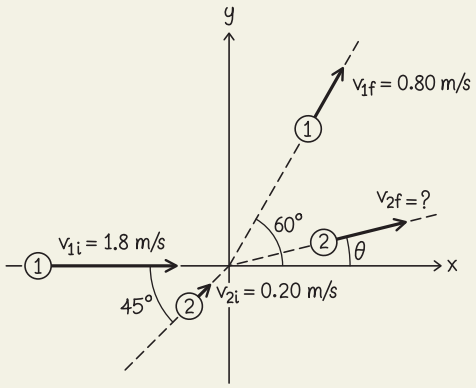
As we saw in Chapter 5, collisions in one dimension are entirely described by two equations: Eq. 4.17, $\Delta\vec{p} = \vec{0}$, which states that the momentum of the isolated system of colliding objects does not change, and Eq. 5.18, $e \equiv v_{12f}/v_{12i}$, which defines the coefficient of restitution. The same two equations also apply to collisions in two dimensions, but because momentum is a vector, Eq. 4.17 now yields two separate equations: one for the momentum in the x direction and the other for the momentum in the y direction. Consider, for example, a collision in an isolated system of two objects of inertia m_1 and m_2. For this system, Eq. 4.17 yields

$$\Delta p_x = \Delta p_{1x} + \Delta p_{2x} = m_1(v_{1x,f} - v_{1x,i}) + m_2(v_{2x,f} - v_{2x,i}) = 0 \qquad (10.21)$$

$$\Delta p_y = \Delta p_{1y} + \Delta p_{2y} = m_1(v_{1y,f} - v_{1y,i}) + m_2(v_{2y,f} - v_{2y,i}) = 0. \qquad (10.22)$$

If we know the initial velocities of the colliding objects, we have values for $v_{1x,i}$, $v_{1y,i}$, $v_{2x,i}$, and $v_{2y,i}$, but these two equations still contain four unknown quantities: $v_{1x,f}$, $v_{1y,f}$, $v_{2x,f}$, and $v_{2y,f}$. To obtain values for these four unknown quantities, we need four equations. Even if we know the coefficient of restitution of the colliding objects, we have only three equations (Eqs. 10.21, 10.22, and 5.18) and so, unlike collisions in one dimension, we cannot determine the outcome of the collision without some additional information about the final velocities.

QUANTITATIVE TOOLS



EXAMPLE 10.7 Pucks colliding

Pucks 1 and 2 slide on ice and collide. The inertia of puck 2 is twice that of puck 1. Puck 1 initially moves at 1.8 m/s; puck 2 initially moves at 0.20 m/s in a direction that makes an angle of 45° with the direction of puck 1. After the collision, puck 1 moves at 0.80 m/s in a direction that makes an angle of 60° with its original direction. What are the speed and direction of puck 2 after the collision?

❶ **GETTING STARTED** Because it takes place on a surface, the collision is two-dimensional. I begin by organizing the given information in a sketch (**Figure 10.33**). I let puck 1 move along the $+x$ axis before the collision. Then I add puck 2, which initially moves at an angle of 45° to the x axis. I draw puck 1 after the collision moving upward and to the right along a line that makes an angle of 60° with the $+x$ axis. I don't know

anything about the motion of puck 2 after the collision, and so I arbitrarily draw it moving to the right and upward. I label the pucks and indicate the speeds I know. I need to determine the final speed v_{2f} of puck 2 and the angle θ between its direction of motion after the collision and the x axis.

Figure 10.33

❷ **DEVISE PLAN** Equations 10.21 and 10.22 give the relationship between the initial and final velocities of the two pucks. I know the x and y components of both initial velocities and, after decomposing $\vec{v}_{1f}$, the x and y components of the final velocity of puck 1. Thus I can use Eqs. 10.21 and 10.22 to obtain values for the two components of $\vec{v}_{2f}$. Using these component values, I can calculate v_{2f} and θ.

❸ **EXECUTE PLAN** The two unknown components are $v_{2x,f}$ and $v_{2y,f}$. Solving Eq. 10.21 for $v_{2x,f}$, I get

$$\begin{aligned} v_{2x,f} &= -\frac{m_1}{m_2}(v_{1x,f} - v_{1x,i}) + v_{2x,i} \\ &= -\tfrac{1}{2}[(0.80\ \text{m/s})\cos 60° - (1.8\ \text{m/s})] \\ &\quad + (0.20\ \text{m/s})\cos 45° \\ &= 0.84\ \text{m/s}. \end{aligned}$$

Solving Eq. 10.22 for $v_{2y,f}$, I get

$$\begin{aligned} v_{2y,f} &= -\frac{m_1}{m_2}(v_{1y,f} - v_{1y,i}) + v_{2y,i} = -\frac{m_1}{m_2}v_{1y,f} + v_{2y,i} \\ &= -\tfrac{1}{2}(0.80\ \text{m/s})\sin 60° + (0.20\ \text{m/s})\sin 45° \\ &= -0.21\ \text{m/s}. \end{aligned}$$

Using these values, I obtain the final speed of puck 2 and its direction of motion:

$$v_{2f} = \sqrt{v_{2x,f}^2 + v_{2y,f}^2} = \sqrt{(0.84\ \text{m/s})^2 + (-0.21\ \text{m/s})^2}$$

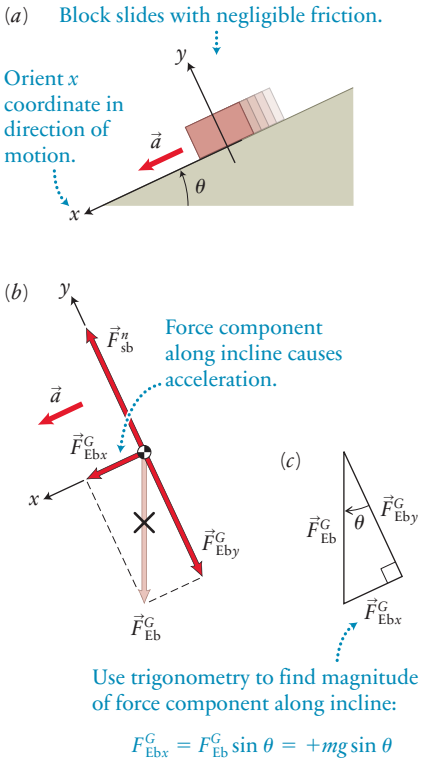
$$= 0.87\ \text{m/s} \checkmark$$

$$\tan\theta = \frac{v_{2y,f}}{v_{2x,f}} = \frac{-0.21\ \text{m/s}}{0.84\ \text{m/s}} = -0.24$$

or $\theta = -14°$ (or 346°.) ✔

❹ **EVALUATE RESULT** My positive result for $v_{2x,f}$ and negative result for $v_{2y,f}$ tell me that after the collision, puck 2 moves in the positive x direction and the negative y direction. Both of these directions make sense: I can see from my sketch that the x component of the velocity of puck 1 decreases in the collision. The corresponding decrease in the x component of its momentum must be made up by an increase in the x component of the momentum of puck 2. Given that puck 2 initially moves in the positive x direction, it must continue to do so after the collision. In the y direction, I note that because $v_{1y,i}$ is zero, the y component of the momentum of puck 1 increases in the positive y direction by an amount $m_1 v_{1y,f} = m_1[(0.80\ \text{m/s})\sin 60°] = m_1(0.69\ \text{m/s})$. Therefore the y component of the momentum of puck 2 must undergo a change of equal amount in the negative y direction. Because the initial y component of the momentum of puck 2 is smaller than this value, $m_2 v_{2y,i} = 2m_1 v_{2y,i} = 2m_1[(0.20\ \text{m/s})\sin 45°] = m_1(0.28\ \text{m/s})$, puck 2 must reverse its direction of motion in the y direction, yielding a negative value for $v_{2y,f}$, in agreement with what I found.

10.10 Is the collision in Example 10.7 elastic?



10.9 Work as the product of two vectors

In Section 9.5, I showed that the work done by a constant force on a rigid object is equal to the product of the force and the force displacement:

$$W = F_x \Delta x_F \quad \text{(constant nondissipative force, one dimension)}. \tag{10.23}$$

Work is a scalar, but force and displacement are vectors. What form does the right side of Eq. 10.23 take if the displacement and the force do not point along the same line? Consider the block sliding down an incline

Figure 10.34 Forces exerted on a block sliding down an incline with negligible friction.

shown in **Figure 10.34*a***. The friction between the block and the surface of the incline is negligible. The (nondissipative) force of gravity exerted on the block does not line up with the block's displacement along the incline. In order to calculate the work done on the block, we evaluate the block's change in kinetic energy ΔK while it slides down the incline. Because there are no changes in the internal energy of the block, the work done on it is equal to ΔK.

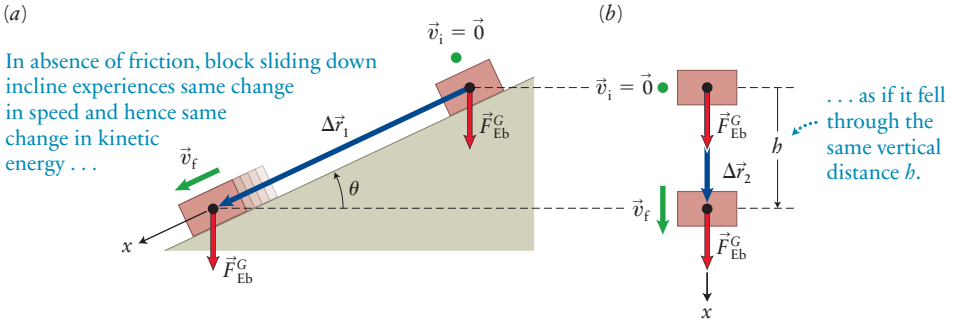
To calculate ΔK, we must first determine the block's acceleration. Let us choose a coordinate system that has the x axis parallel to the incline and the y axis perpendicular to it, as shown in Figure 10.34*a*. The block is subject to two forces: a normal force of magnitude F^n_{sb} exerted by the incline surface and a downward force of gravity of magnitude F^G_{Eb}, which is shown decomposed into components F^G_{Ebx} and F^G_{Eby} in the free-body diagram in Figure 10.34*b*. (There is no tangential component of the contact force because there is no friction.) The x component of $\vec{F}^G_{Eb}$ is what causes the block to accelerate downward. Using trigonometry, we see from Figure 10.34*c* that

$$F^G_{Ebx} = F^G_{Eb}\sin\theta = +mg\sin\theta, \tag{10.24}$$

where we have substituted mg for the magnitude of the force of gravity exerted on the block (Eq. 8.17) and where the plus sign indicates that this component points in the positive x direction. This equation tells us that the magnitude of the downward acceleration of the block is

$$a_x = \frac{\sum F_x}{m} = \frac{F^G_{Ebx}}{m} = \frac{+mg\sin\theta}{m} = +g\sin\theta. \tag{10.25}$$

This is exactly what we found to be the acceleration of a cart rolling down an incline in Section 3.7 (Eq. 3.20). (We now see that the factor $\sin\theta$ in Eq. 3.20 comes from the decomposition of the force of gravity into components parallel and perpendicular to the incline.)



Suppose the block begins at rest on the incline and drops a vertical distance h, as illustrated in **Figure 10.35*a***. If we let the origin coincide with the block's initial position, the block's initial condition is $x_i = 0$, $v_{x,i} = 0$, and its acceleration is given by Eq. 10.25. In order for the block to drop a vertical distance h, its displacement along the incline must be

$$\Delta x = +\frac{h}{\sin\theta}. \tag{10.26}$$

The time the block takes to cover this distance is obtained from Eq. 3.7:

$$\Delta x = v_{x,i}\Delta t + \tfrac{1}{2}a_x(\Delta t)^2 = 0 + \tfrac{1}{2}g\sin\theta(\Delta t)^2, \tag{10.27}$$

Figure 10.35 These blocks gain the same amount of kinetic energy because they descend (without friction) through the same vertical distance h.

and so, from Eqs. 10.26 and 10.27, we obtain

$$(\Delta t)^2 = \frac{2h}{g \sin^2 \theta}. \tag{10.28}$$

The block's final kinetic energy is then

$$\begin{aligned} \tfrac{1}{2}mv_{x,\mathrm{f}}^2 = \tfrac{1}{2}m(v_{x,\mathrm{i}} + a_x\Delta t)^2 &= \tfrac{1}{2}m(0 + g \sin\theta\ \Delta \mathrm{t})^2 \\ &= \tfrac{1}{2}mg^2 \sin^2\theta(\Delta t)^2, \end{aligned} \tag{10.29}$$

where the substitution for $v_{x,\mathrm{f}}$ comes from Eq. 3.4 and that for a_x from Eq. 10.25. Substituting Eq. 10.28 into Eq. 10.29, we obtain

$$\tfrac{1}{2}mv_{x,\mathrm{f}}^2 = \tfrac{1}{2}mg^2 \sin^2\theta\left(\frac{2h}{g \sin^2\theta}\right) = mgh. \tag{10.30}$$

So, because the block's initial kinetic energy is zero, the change in kinetic energy, which is equal to the work done on the block, is

$$W = \Delta K = K_\mathrm{f} - K_\mathrm{i} = \tfrac{1}{2}mv_{x,\mathrm{f}}^2 - 0 = mgh. \tag{10.31}$$

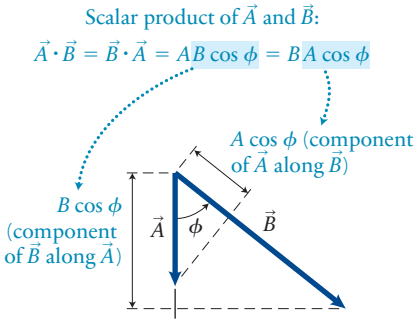
This is the same result we found in Section 7.9 for the change in kinetic energy of a freely falling object! So the work done on the freely falling block in Figure 10.35*b* when it drops a vertical distance h is the same as the work done on the sliding block in Figure 10.35*a* when it drops over the same vertical distance.

Note that we could have obtained the same result for the work done on the block along the incline by calculating the work done on it by *the component of the force of gravity along the incline:*

$$W = F_{\mathrm{Eb}x}^{\mathrm{G}}\Delta x = (+mg \sin\theta)\left(+\frac{h}{\sin\theta}\right) = mgh. \tag{10.32}$$

This means that neither the normal force nor the y component of the force of gravity—both of which are perpendicular to the displacement of the block—does any work on the block. This makes sense because it is the x component of the force of gravity that causes the displacement of the block and that does all the work on it. The forces in the y direction cause no displacement and thus do no work on it.

These results can be stated more compactly by defining a **scalar product** of two vectors. If the angle between two vectors $\vec{A}$ and $\vec{B}$ is ϕ, the scalar product is



$$\vec{A} \cdot \vec{B} \equiv AB \cos\phi. \tag{10.33}$$

The right side of Eq. 10.33 shows that the scalar product of vectors $\vec{A}$ and $\vec{B}$ is a scalar and is equal to the product of the magnitude of vector $\vec{A}$ ($|\vec{A}| \equiv A$) and the component of $\vec{B}$ along $\vec{A}$ ($B \cos\phi$). Note that the scalar product is commutative, so that the result is independent of the order of multiplication:

$$\vec{A} \cdot \vec{B} = \vec{B} \cdot \vec{A} = AB \cos\phi = BA \cos\phi, \tag{10.34}$$

which is shown graphically in **Figure 10.36**. Also, as the name suggests, the scalar product of two vectors is a number with units (a scalar), not a vector.

Figure 10.36 The scalar product of two vectors.

Using the definition of scalar product, we can write **work as a scalar product:**

$$W = \vec{F} \cdot \Delta\vec{r}_F \quad \text{(constant nondissipative force)}. \tag{10.35}$$

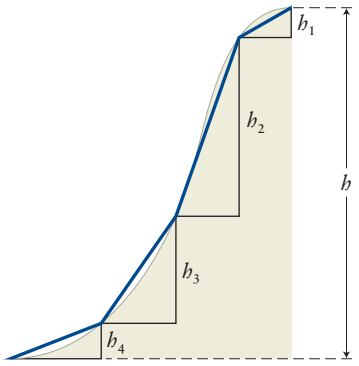
In one dimension, when the force and the force displacement both point along the same line, Eq. 10.35 reduces to our old expression for work, $W = F_x \Delta x_F$ (Eq. 9.8). Note that if the force and the displacement are in opposite directions, $\phi = 180°$, and so $\cos\phi = -1$ and the work is negative.

Because $\cos 90° = 0$, the work done by a force perpendicular to $\Delta\vec{r}_F$ is zero. So for a block sliding down an incline, the normal force does no work and the work done by the force of gravity on the block is

$$W = \vec{F}^G_{\text{Eb}} \cdot \Delta\vec{r}_F = (mg)\left(\frac{h}{\sin\theta}\right)\cos\phi, \tag{10.36}$$

where θ is the angle of the incline and ϕ the angle between $\vec{F}^G_{\text{Eb}}$ and $\Delta\vec{r}_F$. Because $\phi = \frac{\pi}{2} - \theta$ and $\cos\left(\frac{\pi}{2} - \theta\right) = \sin\theta$, we see as before that the work done by the force of gravity on the block is $W = mgh$.

Figure 10.37 An arbitrary incline can be broken into small straight line segments.



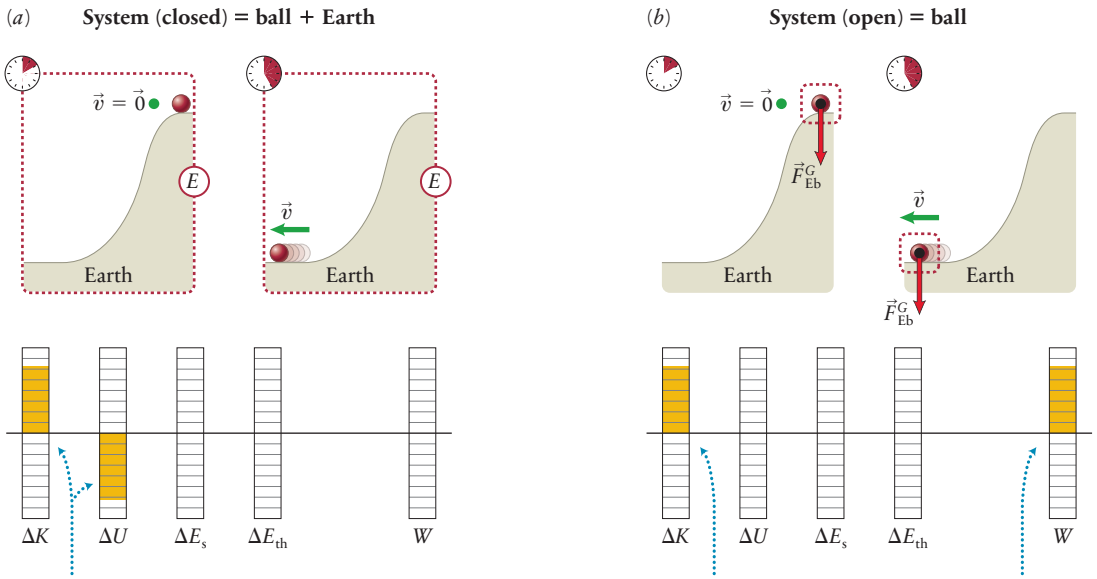


Figure 10.37 shows how we can generalize this result to determine the work done by the gravitational force on an object moving across a surface of any shape. If we approximate the surface by, say, four inclined surfaces, we can apply Eq. 10.36 to each one. The total work done on a block sliding on the surface in Figure 10.37 as it descends from the top to the bottom is

$$W = mgh_1 + mgh_2 + mgh_3 + mgh_4 = mgh. \tag{10.37}$$

To obtain a better approximation we can divide the surface into more, smaller inclined surfaces, but each time we see that the total work done on the block is equal to mgh.

This result also makes sense from an energy perspective. Consider, for example, a ball sliding down the surface of Figure 10.37, and let's assume that there is no friction between the ball and the surface. **Figure 10.38** shows two energy diagrams for this situation. For the closed Earth-ball system

Figure 10.38 Two views of the energy changes that occur when a ball slides down an arbitrary incline with negligible friction.

System gains kinetic energy at expense of its own potential energy; no net change in system's energy.

System gains amount of kinetic energy equal to work done on it by gravitational force.

(Figure 10.38*a*) the change in the ball's kinetic energy ΔK_b and the change in the potential energy of the system add up to zero:

$$\Delta K_b + \Delta U^G = 0. \tag{10.38}$$

From Eq. 7.19, we know that the change in the gravitational potential energy is given by $\Delta U^G = -mgh$, and so

$$\Delta K_b = mgh. \tag{10.39}$$

Next let's consider just the ball by itself as our system (Figure 10.38*b*). There is no change in the ball's internal energy, so the change in the ball's kinetic energy is due to work done on it by the force of gravity: $\Delta K_b = W$. The change in the ball's kinetic energy does not depend on the system chosen, so we see from Eq. 10.39 that the work done on the ball is

$$W = mgh, \tag{10.40}$$

in agreement with Eqs. 10.36 and 10.37. In the process of deriving Eqs. 10.36 and 10.37, however, we derived an expression for the work done by a force that does not point in the same direction as the force displacement (Eq. 10.35).

Let us end by generalizing the result in Eq. 10.35 to a nondissipative force $\vec{F}(\vec{r})$ that is not constant. For such a force we follow the same procedure as in Section 9.7: we divide the force displacement $\Delta\vec{r}_F$ into many small force displacements $\delta\vec{r}_F$, such that the force is approximately constant over each small displacement, and then apply Eq. 10.35 to each small displacement (**Figure 10.39**):

$$W_n \approx \vec{F}(\vec{r}_n) \cdot \delta\vec{r}_{Fn}, \tag{10.41}$$

where $\vec{F}(\vec{r}_n)$ is the force at position $\vec{r}_n$ (at the beginning of each interval, as shown in Figure 10.39). The work done on the system over the entire force displacement $\Delta\vec{r}_F$ is then equal to the sum of the work done over all of the small displacements:

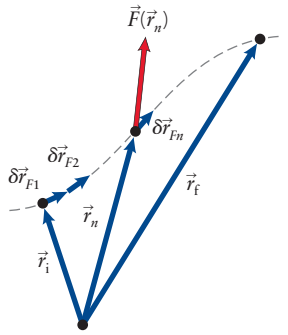
$$W \approx \sum_n W_n = \sum_n \vec{F}(\vec{r}_n) \cdot \delta\vec{r}_{Fn}. \tag{10.42}$$

To get a better approximation, we can divide the force displacement $\Delta\vec{r}_F$ into a larger number of smaller displacements $\delta\vec{r}_{Fn}$, so that the variation of the force over each displacement becomes even smaller. An exact result is obtained if we let $\delta\vec{r}_{Fn}$ approach zero (and the number of small displacements approaches infinity):

$$W = \lim_{\delta\vec{r}_{Fn}\to 0} \sum_n \vec{F}(\vec{r}_n) \cdot \delta\vec{r}_{Fn}, \tag{10.43}$$

which is the definition of the line integral (Appendix B) of the force:

$$W = \int_{\vec{r}_i}^{\vec{r}_f} \vec{F}(\vec{r}) \cdot d\vec{r} \quad \text{(variable nondissipative force)}, \tag{10.44}$$



where the line integral should be evaluated over the path traced out by the point of application of the force.

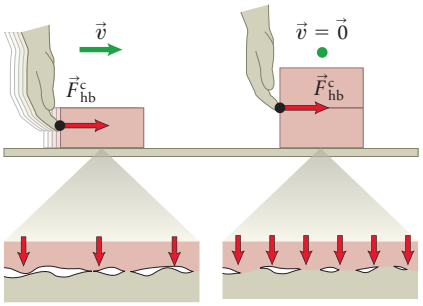
For dissipative forces, we can follow the same procedure of dividing up the displacement to our approach of Section 9.7. Equation 9.27 then replaces Eq. 10.35, yielding for the change in thermal energy caused by the dissipative force:

$$\Delta E_{th} = -\int_{\vec{r}_i}^{\vec{r}_f} \vec{F}(\vec{r}_{cm}) \cdot d\vec{r}_{cm} \quad \text{(variable dissipative force)}. \tag{10.45}$$

Note that, in contrast to Eq. 10.44, this expression contains the position of the center of mass of the system rather than the point of application of the force.

Figure 10.39 To evaluate the work done on a system by a variable force, we divide the force displacement into small pieces.

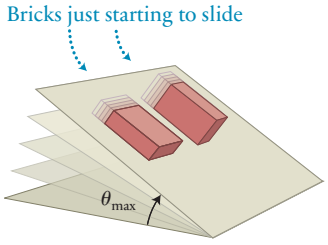
10.11 When is W in Eq. 10.40 positive, and when is it negative? Is your answer consistent with the definition of positive and negative work given in Section 9.2?



10.10 Coefficients of friction

To describe the motion of objects along surfaces, we need a quantitative expression for the force of friction. Like the normal force, the force of static friction can take on a range of values, depending on the situation.

Suppose you are still struggling with the file cabinet of Checkpoint 10.4. As you increase the strength of your push on the cabinet, the force of static friction opposing your push grows. If you change the direction of your push, the force of friction changes direction as well, always opposing your force. The force of static friction has a maximum value, however, evidenced by the fact that if you push hard enough, the cabinet starts sliding. So the question is: What is the *maximum* force of static friction in a given situation?



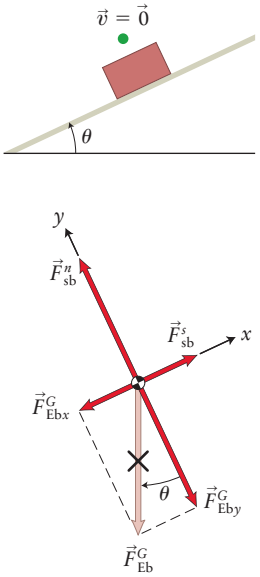
The answer to this question depends on many variables, but we can establish a number of basic facts. For example—this you know from experience—the maximum force of static friction depends on the force with which the surfaces press against each other. An empty file cabinet slides more easily than a full one, for instance, and the double brick in **Figure 10.40** requires twice as large a force to begin sliding as the single brick does. The reason for this dependence on load is shown in Figure 10.40. If you put a brick down on a large flat plate, the *contact area* between the brick and the plate is given by the surface area of the face of the brick that is touching the plate. At the microscopic level, however, surfaces are never completely flat, so the surfaces of the brick and the plate touch only at the tops of protrusions over a combined *effective contact area* that is much smaller than the contact area (typically only about 1/10,000 of it). When the load increases, protrusions on the surfaces flatten, and the effective contact area increases, strengthening the bond between the surfaces.

Figure 10.40 On a rough surface, a single brick slides more easily than a double brick. The harder two surfaces press against each other, the larger the effective contact area, and consequently the stronger the bond between the surfaces.

Measurements show that the angle θ_{max} at which objects begin to slide down an incline (in other words, the angle at which the force of static friction reaches its maximum value) does not depend on the contact area. As illustrated in **Figure 10.41**, two identical bricks begin sliding at the same incline angle regardless of the contact area between the brick and the incline surface. I know it is counterintuitive that the contact area does not determine when the bricks begin to slide, but to understand what is going on, let's go to the microscopic level again. When the brick is oriented so that its largest face is in contact with the inclined surface, the force exerted by the brick on the inclined surface is spread out over a large number of contact points, with the effective contact area having a certain value. When the brick is on its side, there are fewer contact points, but each point now carries a greater share of the load and so flattens out more. This flattening increases the contact area available at each point, with the result that the effective contact area has the same value as when the brick was in the other orientation. Thus the effective contact area doesn't depend on the orientation of the brick—it depends only on the force with which the brick presses against the surface. These observations establish the following important point:

Figure 10.41 Regardless of its orientation, a brick starts sliding at the same angle of incline.

> **The maximum force of static friction exerted by a surface on an object is proportional to the force with which the object presses on the surface and does not depend on the contact area.**



To obtain an expression for the force with which an object presses on an inclined surface, consider **Figure 10.42**. The normal force $\vec{F}^{n}_{sb}$ exerted by

the surface on the block and the normal force $\vec{F}^n_{bs}$ with which the surface of the block presses against the inclined surface (not shown in Figure 10.42) are an interaction pair and therefore equal in magnitude. As we have just determined, the maximum magnitude of the force of static friction is proportional to F^c_{bs} and therefore must also be proportional to F^n_{sb}, $(F^s_{sb})_{max} = \mu_s F^n_{sb}$. For any two surfaces 1 and 2, we can therefore write

$$(F^s_{12})_{max} = \mu_s F^n_{12}. \tag{10.46}$$

The maximum magnitude of the force of static friction between two surfaces is proportional to the magnitude of the normal force exerted by the surfaces on each other. The unitless proportionality constant μ_s is called the **coefficient of static friction.** Its value depends on the two materials in contact and the condition of their surfaces. Values for a few representative materials are given in **Table 10.1**.

Figure 10.42 Free-body diagram for a block at rest on an inclined surface.

10.12 (*a*) A brick slides more easily on ice than on wood. For which combination (brick on ice or brick on wood) is μ_s larger? (*b*) For rubber on dry asphalt, μ_s is about 1. Ignoring any limits due to the runner's skill and condition, what maximum acceleration without slipping can a runner achieve using rubber soles on a dry, horizontal asphalt surface? [Hint: See Figure 10.21.]

The coefficient of static friction expressed in terms of the angle of incline can readily be determined experimentally by raising the incline of Figure 10.42 to the maximum angle at which the block remains at rest. At that angle θ_{max}, the force of static friction $\vec{F}^s_{sb}$ reaches the maximum value given by Eq. 10.46, and because the block remains at rest, the forces along the x axis must add to zero:

$$\Sigma F_x = F^G_{Ebx} + (F^s_{sb})_{max} = 0 \tag{10.47}$$

and so

$$(F^s_{sb})_{max} = -F^G_{Ebx}. \tag{10.48}$$

Table 10.1 Coefficients of friction

Material 1	Material 2	μ_s	μ_k
aluminum	aluminum	1.1–1.4	1.4
aluminum	steel	0.6	0.5
glass	glass	0.9–1.0	0.4
glass	nickel	0.8	0.6
ice	ice	0.1	0.03
rubber	aluminum	0.5	—
rubber	concrete	1.0–4.0	0.8
rubber	rubber	0.84	—
steel	steel	0.8	0.4
steel	brass	0.5	0.4
steel	copper	0.5	0.4
steel	lead	0.95	0.95
wood	wood	0.25–0.5	0.2

The values given are for clean, dry, smooth surfaces.

Because the block has no acceleration in the y direction, we also have

$$\Sigma F_y = F^n_{\text{sb}} + F^G_{\text{Eb}y} = 0, \tag{10.49}$$

and so

$$F^n_{\text{sb}} = -F^G_{\text{Eb}y}. \tag{10.50}$$

Substituting Eqs. 10.48 and 10.50 into 10.46, we get

$$-F^G_{\text{Eb}x} = \mu_s(-F^G_{\text{Eb}y}) \tag{10.51}$$

$$\mu_s = \frac{F^G_{\text{Eb}x}}{F^G_{\text{Eb}y}}. \tag{10.52}$$

Looking at Figure 10.42, we see that $F^G_{\text{Eb}x}/F^G_{\text{Eb}y}$ is the tangent of θ and so

$$\mu_s = \tan\theta_{\text{max}}. \tag{10.53}$$

10.13 (*a*) To what angle θ_{max} does a coefficient of static friction of 1 correspond? (*b*) Put, in turn, a coin, a paper clip, a cell phone, and a comb on the cover of this book and tilt the book to obtain the angle at which each object begins to slide. In each case, how close do you get to the angle calculated in part *a*? What do you conclude from these observations about the coefficients of static friction for these combinations of surfaces?

Equation 10.46 gives only the *maximum* value of the force of static friction. All we know in any situation in which this force is present but has not reached its maximum value is that the magnitude of the force of static friction exerted by surface 1 on surface 2 must obey the condition

$$F^s_{12} \leq \mu_s F^n_{12}, \tag{10.54}$$

where F^n_{12} is the magnitude of the normal force exerted by surface 1 on surface 2. How, then, can you determine the magnitude of the frictional force exerted on an object in a given situation? Inequality 10.54 is not of much help, especially because the normal force can also take on almost any value! The key is to use what you know about the object's motion: If you know its acceleration and inertia, you can use the equation of motion, $\vec{a} = \Sigma\vec{F}/m$, to determine the vector sum of the forces exerted on the object. If you know what other forces are exerted on it, you can extract the values of the normal and frictional forces from this sum. The general procedure for dealing with situations involving frictional forces at surfaces is explained in the Procedure box "Working with frictional forces."

PROCEDURE: Working with frictional forces

1. Draw a free-body diagram for the object of interest. Choose your x axis parallel to the surface and the y axis perpendicular to it, then decompose your forces along these axes. Indicate the acceleration of the object.
2. The equation of motion in the y direction allows you to determine the sum of the y components of the forces in that direction:

   $$\Sigma F_y = ma_y.$$

   Unless the object is accelerating in the normal direction, $a_y = 0$. Substitute the y components of the forces from your free-body diagram. The resulting equation allows you to determine the normal force.
3. The equation of motion in the x direction is

   $$\Sigma F_x = ma_x.$$

   If the object is not accelerating along the surface, $a_x = 0$. Substitute the x components of the forces from your free-body diagram. The resulting equation allows you to determine the frictional force.
4. If the object is not slipping, the normal force and the force of static friction should obey Inequality 10.54.

EXAMPLE 10.8 Pulling a friend up a hill

A hiker is helping a friend up a hill that makes an angle of 30° with level ground. The hiker, who is farther up the hill, is pulling on a cable attached to his friend. The cable is parallel to the hill so that it also makes an angle of 30° with the horizontal. If the coefficient of static friction between the soles of the hiker's boots and the surface of the hill is 0.80 and his inertia is 65 kg, what is the maximum magnitude of the force he can exert on the cable without slipping?

1 GETTING STARTED I begin by making a sketch and drawing the free-body diagram for the hiker (**Figure 10.43**). I chose an x axis that points up the hill and the y axis perpendicular to it. The forces exerted on the hiker are a force $\vec{F}^{c}_{ch}$ exerted by the cable and directed down the hill (this force forms an interaction pair with the force the hiker exerts on the cable), the force of gravity $\vec{F}^{G}_{Eh}$, and the contact force exerted by the surface of the hill on the hiker. This last force has two components: the normal force $\vec{F}^{n}_{sh}$ and the force of static friction $\vec{F}^{s}_{sh}$. The force of static friction is directed up the hill. If the hiker is not to slip, his acceleration must be zero, and so the forces in the normal (y) and tangential (x) directions must add up to zero.

Figure 10.43

2 DEVISE PLAN As suggested in the Procedure box on page 338, I'll write the equation of motion along the two axes, setting the acceleration in each direction to zero. Then I use Inequality 10.54 to determine the maximum force that the hiker can exert without slipping.

3 EXECUTE PLAN Because the magnitude of the force of gravity exerted on the hiker is mg, I have in the y direction

$$\Sigma F_y = F^{G}_{Eh\,y} + F^{n}_{sh} = -mg\cos\theta + F^{n}_{sh} = ma_y = 0$$

$$F^{n}_{sh} = mg\cos\theta, \qquad (1)$$

where the minus sign in $-mg\cos\theta$ indicates that $F^{G}_{Eh\,y}$ is in the negative y direction. Likewise, I have in the x direction

$$\Sigma F_x = F^{G}_{Eh\,x} + F^{s}_{sh} - F^{c}_{ch}$$

$$= -mg\sin\theta + F^{s}_{sh} - F^{c}_{ch} = ma_x = 0$$

$$F^{s}_{sh} = mg\sin\theta + F^{c}_{ch}. \qquad (2)$$

If the hiker is not to slip, the force of static friction must not exceed its maximum value. Substituting Eqs. 1 and 2 into Inequality 10.54, I get

$$mg\sin\theta + F^{c}_{ch} \le \mu_s(mg\cos\theta)$$

$$F^{c}_{ch} \le mg(\mu_s\cos\theta - \sin\theta).$$

The problem asks me about the magnitude F^{c}_{hc} of the force exerted *by* the hiker *on* the cable, which is the same as the magnitude F^{c}_{ch} of the force exerted *by* the cable *on* the hiker, so

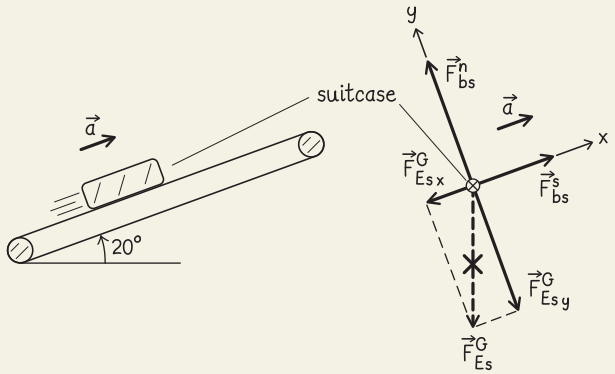
$$F^{c}_{hc} \le mg(\mu_s\cos\theta - \sin\theta).$$

Substituting the values given, I obtain

$$F^{c}_{hc} \le (65\text{ kg})(9.8\text{ m/s}^2)(0.80\cos 30° - \sin 30°)$$

$$= 1.2\times10^2\text{ N}. \checkmark$$

4 EVALUATE RESULT A force of 1.2×10^2 N corresponds to the gravitational force exerted by Earth on an object that has an inertia of only 12 kg, and so the hiker cannot pull very hard before slipping. I know from experience, however, that unless I can lock a foot behind some solid object, it is impossible to pull hard on an inclined surface, and thus the answer I obtained makes sense.



EXAMPLE 10.9 Object accelerating on a conveyor belt

While designing a conveyor belt system for a new airport, you determine that, when a typical suitcase is moving up an incline of 20°, the magnitude of the maximum forward acceleration a rubber belt can give such a suitcase before the suitcase begins slipping is 4.0 m/s^2. What is the coefficient of static friction for a typical suitcase on rubber?

1 GETTING STARTED I begin by making a sketch and drawing a free-body diagram for the suitcase, choosing the x axis along the conveyor belt in the direction of acceleration and the y axis upward and perpendicular to it (**Figure 10.44**). I also draw the upward acceleration of the suitcase along the incline.

2 DEVISE PLAN As in Example 10.8, I write out the equation of motion along both axes. The x component of the

Figure 10.44

(Continued)

acceleration is $a_x = +a$, where the magnitude of the acceleration is $a = 4.0\ \text{m/s}^2$. I can then use Inequality 10.54 to determine the coefficient of static friction.

3 EXECUTE PLAN The equations of motion in the x and y directions are

$$\Sigma F_x = F^G_{\text{Es}x} + F^s_{\text{bs}} = -mg\sin\theta + F^s_{\text{bs}} = ma_x \qquad (1)$$

$$\Sigma F_y = F^G_{\text{Es}y} + F^n_{\text{bs}} = -mg\cos\theta + F^n_{\text{bs}} = ma_y = 0, \qquad (2)$$

with m the inertia of the suitcase. If a_x represents the maximum acceleration at which the suitcase does not slip, the force of static friction must be maximum. Substituting Eq. 10.46 for $(F^s_{\text{bs}})_{\text{max}}$ into Eq. 1, I get

$$-mg\sin\theta + \mu_s F^n_{\text{bs}} = m(+a).$$

Solving this equation for μ_s and substituting $F^n_{\text{bs}} = mg\cos\theta$ from Eq. 2, I obtain

$$\mu_s = \frac{ma + mg\sin\theta}{mg\cos\theta} = \frac{a + g\sin\theta}{g\cos\theta}$$

$$= \frac{(4.0\ \text{m/s}^2) + (9.8\ \text{m/s}^2)\sin 20^\circ}{(9.8\ \text{m/s}^2)(\cos 20^\circ)} = 0.80. \checkmark$$

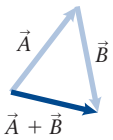
4 EVALUATE RESULT From Table 10.1, I see that the value I obtained for the coefficient for static friction is close to the coefficient for rubber against rubber and therefore reasonable. I also note that the inertia m of the suitcase, which is not given, drops out of the final result.

Once surfaces slip relative to each other, the force of kinetic friction, like its static counterpart, is proportional to the normal force: It takes a greater force to keep a heavily loaded file cabinet moving than it does to keep an empty one moving. Experiments also show that objects sliding to a stop on a horizontal surface under the influence of kinetic friction undergo a constant acceleration; in other words, the force of kinetic friction between two slipping surfaces is constant and independent of the relative velocity of the two surfaces. In analogy to Eq. 10.46, we can say

$$F^k_{12} = \mu_k F^n_{12}, \qquad (10.55)$$

where μ_k is called the **coefficient of kinetic friction.** The kinetic coefficient μ_k is always smaller than μ_s (or else an object would never slip because it would "stop slipping the instant it starts slipping"). For most surface combinations, the value of μ_k is somewhere between 25% and 100% of the corresponding value of μ_s (Table 10.1).

Note that, unlike the force of static friction, which can take on any value below the maximum limit dictated by μ_s, the force of kinetic friction is constant and therefore always equal to the value given in Eq. 10.55.



10.14 Imagine putting a single and a double brick on a flat board, as in Figure 10.40, and then slowly raising one end of the board. (*a*) Does the single brick begin to slide before, after, or at the same time as the double brick? (*b*) Once the bricks start sliding, is the acceleration of the double brick larger than, equal to, or smaller than that of the single brick?

QUANTITATIVE TOOLS

Chapter Summary

Vectors in two dimensions (Sections 10.1, 10.2, 10.6, 10.9)

Concepts To add two vectors $\vec{A}$ and $\vec{B}$, place the tail of $\vec{B}$ at the head of $\vec{A}$. Their sum is the vector drawn from the tail of $\vec{A}$ to the head of $\vec{B}$.

To subtract vector $\vec{B}$ from vector $\vec{A}$, reverse the direction of $\vec{B}$ and then add the reversed $\vec{B}$ to $\vec{A}$.

Any vector $\vec{A}$ can be written as

$$\vec{A} = A_x\hat{\imath} + A_y\hat{\jmath}, \tag{10.5}$$

where A_x and A_y are the *components* of $\vec{A}$ along the x and y axes. The x component of $\vec{A}$ is the projection of $\vec{A}$ on the x axis, and the y component is the projection of $\vec{A}$ on the y axis. The components A_x and A_y are signed numbers and can be negative.

Quantitative Tools The magnitude of any vector $\vec{A}$ is

$$A \equiv |\vec{A}| = +\sqrt{A_x^2 + A_y^2} \tag{10.6}$$

and the angle θ that $\vec{A}$ makes with the positive x axis is given by

$$\tan\theta = \frac{A_y}{A_x}. \tag{10.7}$$

If $\vec{R} = \vec{A} + \vec{B}$ is the vector sum of $\vec{A}$ and $\vec{B}$, the components of $\vec{R}$ are

$$\begin{aligned} R_x &= A_x + B_x \\ R_y &= A_y + B_y. \end{aligned} \tag{10.9}$$

The **scalar product** of two vectors $\vec{A}$ and $\vec{B}$ that make an angle ϕ when placed tail to tail is

$$\vec{A}\cdot\vec{B} \equiv AB\cos\phi. \tag{10.33}$$

Projectile motion in two dimensions (Section 10.7)

Concepts For a projectile that moves near Earth's surface and experiences only the force of gravity, the acceleration has magnitude g and is directed downward. The projectile's horizontal acceleration is zero, and the horizontal component of its velocity remains constant.

At the highest point in the trajectory of a projectile, the vertical velocity component v_y is zero, but the vertical component of the acceleration is g and is directed downward.

Quantitative Tools If a projectile is at a position (x, y), its **position vector** $\vec{r}$ is

$$\vec{r} = x\hat{\imath} + y\hat{\jmath}. \tag{10.10}$$

If a projectile has position components x_i and y_i and velocity components $v_{x,\mathrm{i}}$ and $v_{y,\mathrm{i}}$ at one instant, then its acceleration, velocity, and position components a time interval Δt later are

$$a_x = 0$$

$$a_y = -g$$

$$v_{x,\mathrm{f}} = v_{x,\mathrm{i}} \tag{10.17}$$

$$v_{y,\mathrm{f}} = v_{y,\mathrm{i}} - g\Delta t \tag{10.18}$$

$$x_\mathrm{f} = x_\mathrm{i} + v_{x,\mathrm{i}}\Delta t \tag{10.19}$$

$$y_\mathrm{f} = y_\mathrm{i} + v_{y,\mathrm{i}}\Delta t - \tfrac{1}{2}g(\Delta t)^2. \tag{10.20}$$

Collisions and momentum in two dimensions (Section 10.8)

Concepts Momentum is a vector, so in two dimensions changes in momentum must be accounted for by components. This means two equations, one for x and one for y components of momentum. The coefficient of restitution is a scalar and is accounted for by a single equation.

Quantitative Tools

$$\Delta p_x = \Delta p_{1x} + \Delta p_{2x} = m_1(v_{1x,\mathrm{f}} - v_{1x,\mathrm{i}}) + m_2(v_{2x,\mathrm{f}} - v_{2x,\mathrm{i}}) = 0 \tag{10.21}$$

$$\Delta p_y = \Delta p_{1y} + \Delta p_{2y} = m_1(v_{1y,\mathrm{f}} - v_{1y,\mathrm{i}}) + m_2(v_{2y,\mathrm{f}} - v_{2y,\mathrm{i}}) = 0. \tag{10.22}$$

Forces in two dimensions (Sections 10.2, 10.3)

Concepts In two-dimensional motion, the component of the acceleration parallel to the instantaneous velocity changes the speed and the component of the acceleration perpendicular to the instantaneous velocity changes the direction of the instantaneous velocity.

When choosing a coordinate system for a problem dealing with an accelerating object, if possible make one of the axes lie along the direction of the acceleration.

Friction (Sections 10.4, 10.10)

Concepts When two surfaces touch each other, the component of the contact force perpendicular (normal) to the surfaces is called the **normal force** and the component parallel (tangential) to the surfaces is called the **force of friction.**

The direction of the force of friction is such that the force opposes *relative* motion between the two surfaces.

When the surfaces are not moving relative to each other, we have **static friction.** When they are moving relative to each other, we have **kinetic friction.**

The magnitude of the force of kinetic friction is independent of the contact area and independent of the relative speeds of the two surfaces.

Quantitative Tools The maximum magnitude of the force of static friction between any two surfaces 1 and 2 is proportional to the normal force:

$$(F_{12}^s)_{\max} = \mu_s F_{12}^n, \tag{10.46}$$

where μ_s is the unitless **coefficient of static friction.** This upper limit means that the magnitude of the frictional force must obey the condition

$$F_{12}^s \leq \mu_s F_{12}^n. \tag{10.54}$$

The magnitude of the force of kinetic friction is also proportional to the normal force:

$$F_{12}^k = \mu_k F_{12}^n, \tag{10.55}$$

where $\mu_k \leq \mu_s$ is the unitless **coefficient of kinetic friction.**

Work (Sections 10.5, 10.9)

Concepts For a sliding object, the normal force does no work because this force is perpendicular to the direction of the object's displacement.

The force of kinetic friction is a nonelastic force and thus causes energy dissipation.

The force of static friction is an elastic force and so causes no energy dissipation.

The work done by gravity is independent of path.

Quantitative Tools The work done by a constant nondissipative force when the point of application of the force undergoes a displacement $\Delta\vec{r}_F$ is

$$W = \vec{F} \cdot \Delta\vec{r}_F. \tag{10.35}$$

The work done by a variable nondissipative force when the point of application of the force undergoes a displacement is

$$W = \int_{\vec{r}_i}^{\vec{r}_f} \vec{F}(\vec{r}) \cdot d\vec{r}. \tag{10.44}$$

This is the line integral of the force over the path traced out by the point of application of the force.

For a variable dissipative force, the change in the thermal energy is

$$\Delta E_{\text{th}} = -\int_{\vec{r}_i}^{\vec{r}_f} \vec{F}(\vec{r}_{\text{cm}}) \cdot d\vec{r}_{\text{cm}}. \tag{10.45}$$

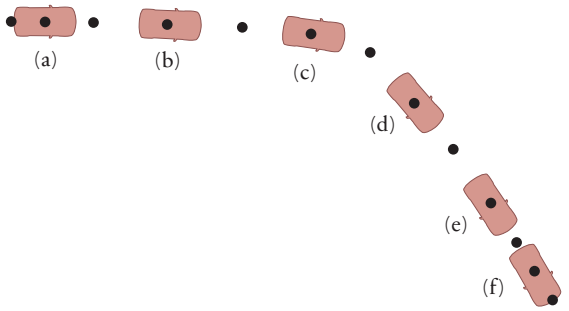
When an object descends a vertical distance h, no matter what path it follows, the work gravity does on it is

$$W = mgh. \tag{10.40}$$

Questions and Problems

For instructor-assigned homework, go to Mastering Physics

Dots indicate difficulty level of problems: • = *easy*, •• = *intermediate*, ••• = *hard*; CR = *context-rich problem.*



10.1 *Straight* is a relative term

1. Suppose a missile that was launched vertically moves along a trajectory and has a constant vertical speed and a constant horizontal acceleration. What is the shape of this trajectory as seen by a stationary observer? •
2. Riding in a train on horizontal tracks, you notice a boy drop a baseball from the roof of his house nearby. (*a*) What is the shape of the trajectory you see for the ball if the train is moving at constant speed? (*b*) Would you see the trajectory as a straight line if the train were accelerating? ••
3. You are performing an experiment similar to the one shown in Figure 10.1. The ball is dropped from a height of $y_i = 0.200$ m on the pole above the cart just as the pole and cart pass your origin of coordinates. The ball lands inside the cart at the instant the cart passes the location $x = +0.0600$ m. The lab exercise includes, among other things, that you determine the distance traveled by the ball from when it is released until it lands in the cart. Your lab partner immediately says "0.200 m," but the girl at the next table says "0.0600 m." The lab partners just behind you are arguing about whether it is 0.209 m or 0.214 m. You have not done the calculation, but of these four numbers, which could be correct? ••

10.2 Vectors in a plane

4. Is it possible for the acceleration and velocity vectors of an object to *always* be in exactly opposite directions? If no, explain why not. If yes, describe the motion. •
5. A baseball player hits a long fly ball to center field. What can we say about the direction of the ball's acceleration at the highest point of its flight? (Consider air resistance.) •
6. Can an object be accelerated without changing its kinetic energy? •
7. (*a*) Can two vectors of unequal lengths add up to zero? (*b*) What about three vectors of unequal lengths? ••
8. Three swimmers who all swim at the same speed discuss how to cross a river in the shortest amount of time. Swimmer A will swim straight across the river at a right angle to the current. Swimmer B reasons that the current will carry A downstream, meaning that A will cover a greater distance to get across and therefore will take a longer time interval. B says he will aim at an upstream angle such that, allowing for the current, he will reach the other side directly across from where he starts, thus covering the shortest distance and arriving first. Swimmer C, reasoning that the time interval needed for B to cross will be longer than B expects because some of B's effort will be spent battling the current, plans to aim at a downstream angle, so that the current assists rather than opposes him. This way he will be traveling at the highest speed and get across first. Which swimmer gets across first? ••
9. Figure P10.9 shows the position of a regularly flashing light on top of a car (bird's-eye view) as the car moves from (a) to (f). Describe the acceleration of the car at each labeled position based on the information in the figure. ••

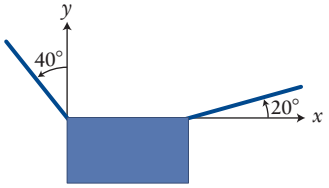


Figure P10.9

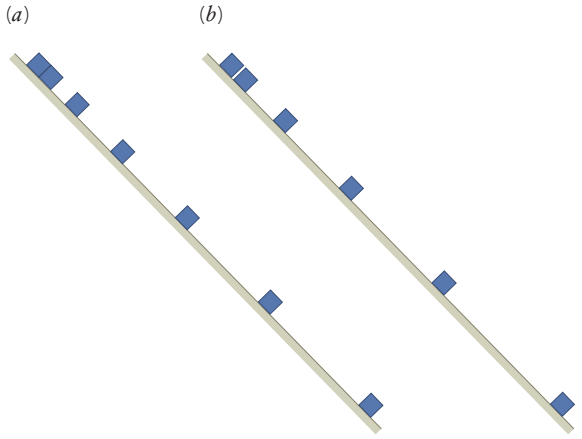
10.3 Decomposition of forces

10. You are sweeping the floor with a long-handled broom, with the handle making an acute angle to the horizontal floor. Is it easier to push the broom or pull it? Why? •
11. A sweater hanging on a clothesline makes the line sag in the center. Could you tighten the clothesline enough (assuming whatever material for the line you want) to eliminate the sag completely? ••
12. A sign is suspended by two wires as shown in Figure P10.12. Is the tension in each wire *larger than*, *equal to*, or *smaller than* the gravitational force exerted on the sign by Earth? ••

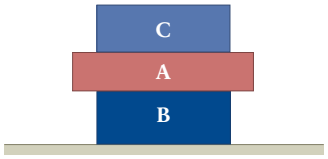
Figure P10.12



13. A man is crossing a roof that is inclined at an angle of 30° above the horizontal. His path takes him parallel to the roof ridge but 4.0 m (along the roof surface) below the peak. He is supported by two ropes, one attached to an object above each end of the roof. The left rope is attached to a chimney at 1.0 m above the peak of the roof; the right rope is attached to a flagpole at 3.0 m above the peak of the roof. The chimney rope runs parallel to the roof surface, but the flagpole rope does not. Both ropes reach the man at waist level. When the man is halfway across the 10-m-wide roof, describe each force that acts on the man, and identify which have components in each of three perpendicular directions: parallel to the roof ridge, normal to the roof surface, and tangential to the roof surface. •••

10.4 Friction

14. A common parlor trick is to yank a tablecloth hard so that any dishes and glasses on the cloth stay put instead of falling onto the floor. (*a*) Explain how this happens. (*b*) Why, if you pull on the cloth too slowly, do the dishes and glasses get dragged off the table? •
15. A pool ball that is struck gently will roll smoothly across the felt surface of a pool table. However, it is possible to strike the ball in a way that produces "backspin", such that the ball is rotating in the opposite direction to its normal rolling motion as it moves across the table. Describe the nature of the friction force between the table and the ball in these two cases in terms of static or kinetic friction. •



16. Figure P10.16 represents two stroboscopic pictures (taken at the same flash rate) of a block moving along a ramp that exerts a frictional force on the block. In one sketch, the block is released from rest at the top of the ramp and moves downward. In the other sketch, the block is placed at the bottom of the ramp and shoved up the ramp. Which sketch is for the downward motion? Which is for the upward motion? •

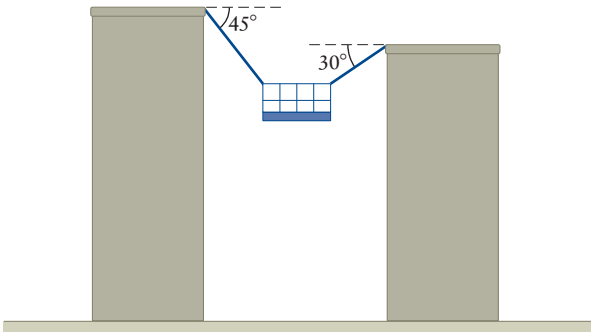
Figure P10.16

17. You keep a chalkboard eraser pressed against the chalkboard by using your finger to exert a horizontal force on the back of the eraser. (*a*) Which type of force (call it force A) keeps the eraser from falling? (*b*) What is the magnitude of force A? (*c*) Does the magnitude of force A (which keeps the eraser from falling) depend on how hard you press? (*d*) Now release your finger so that the eraser falls. What happens to the magnitude of force A now? ••
18. In Figure P10.18, all surfaces experience friction. Is the magnitude of the horizontal component of the force exerted by A on B greater than, equal to, or less than the magnitude of the horizontal force exerted by A on C if the system of blocks is (*a*) moving at a constant velocity to the right and (*b*) accelerating to the right due to an external force exerted on B? ••

Figure P10.18

19. A factory worker pulls on a rope attached to a pallet loaded with a crate, dragging the combination at constant speed across a rough factory floor. The tension in the rope acts horizontally on the pallet. Draw a free-body diagram for the pallet and one for the crate when the pallet (*a*) is on level ground and (*b*) is being pulled up an incline. The velocity is constant in both situations. ••

10.5 Work and friction



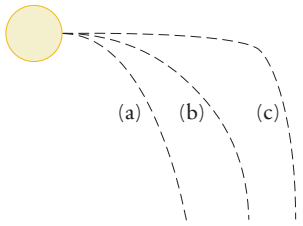
20. What is the direction of the frictional force exerted on a coffee cup (*a*) sitting on a stationary table, (*b*) being pulled to the right across a table, and (*c*) sitting on a table while the table is dragged to the right? •
21. You and a friend are standing on the icy surface of a frozen pond. You are wearing boots with cleats that grip the ice, but your friend has smooth-soled shoes that slip a bit when they move their feet. Discuss how you can both walk across the pond in terms of work and friction. •
22. A resort uses a rope to pull a 65-kg skier up a slope at constant speed. To pull the skier 75 m requires 18 kJ of work to be done by the rope. (*a*) Determine the tension in the rope if the snow is slick enough to allow you to ignore any frictional effects. (*b*) What angle does the slope make to the horizontal? ••
23. A friend claims that her car can accelerate from a stop to 60 mi/h (26.8 m/s) in 5.1 s, but the speedometer is broken. You decide to test her claim by riding with her, and you bring along a small metal washer, a short length of string, a protractor, and a pen that can write on glass. Sitting in the passenger seat, you tie the washer to one end of the string and then let the string-washer combination hang straight down by rolling up the passenger-door window to pinch the free end of the string. While the car is stationary, you draw a line on the window alongside the vertical string. (*a*) How large is the angle the string makes with the line you drew if the car accelerates at the rate your friend claims? (*b*) If an identical washer does not slide on the horizontal dashboard while this is happening, what is the ratio of the frictional force to the gravitational force exerted on this washer? ••
24. You drive a car onto a 100-vehicle ferry, park, and have a short nap. When the ferry arrives at its destination, you start the car and drive off to begin your vacation. Estimate the magnitude of work done by the forces of static friction between the car tires and either the roadway or the ferry surface during each portion of this journey. ••
25. Two children slide down playground slides of identical heights but different angles, one shallow and one steep. (*a*) Suppose the slides are so slippery that the force of friction is negligibly small. Which child, if either, moves faster at the bottom of the slide? Which one, if either, arrives at the bottom first? (*b*) Now take into account the kinetic friction between the child and the slide. Which child, if either, moves faster at the bottom of the slide? ••

10.6 Vector algebra

26. For the vectors $\vec{A} = 2.0\hat{\imath} + 3.0\hat{\jmath}$ and $\vec{B} = -4.0\hat{\imath} + 5.0\hat{\jmath}$, calculate (*a*) $\vec{A} + \vec{B}$ and (*b*) $\vec{A} - \vec{B}$. (*c*) If the direction (but not the magnitude) of $\vec{B}$ is allowed to change by any amount you like, how large can $|\vec{A} + \vec{B}|$ be? How small? •
27. For the vectors $\vec{A} = 4.0\hat{\imath} - 3.0\hat{\jmath}$ and $\vec{B} = -2.0\hat{\imath} + 2.0\hat{\jmath}$, determine (*a*) $\vec{A} - \vec{B}$ and (*b*) $|\vec{A} - \vec{B}|$. •
28. Determine the polar coordinates of vectors (*a*) $\vec{A} = 3.0\hat{\imath} + 2.0\hat{\jmath}$ and (*b*) $\vec{B} = -2.0\hat{\imath} + 2.0\hat{\jmath}$. •
29. Your directions on a scavenger hunt map direct you to walk 55 m north, then 38 m southwest, and finally 12 m east. With the positive x direction being east, what is your displacement (*a*) in Cartesian coordinates and (*b*) in polar coordinates? ••
30. In Figure P10.30, if the tension in the cable attaching the platform to the building on the right is 800 N, what are

(*a*) the tension in the cable attaching the platform to the building on the left and (*b*) the inertia of the platform? ●●

Figure P10.30

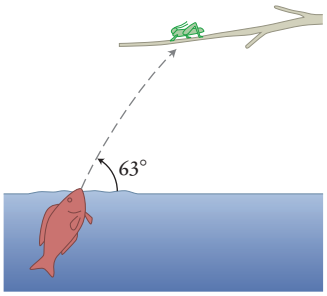


31. You leave your house and walk east for 1.0 h, northeast for 1.5 h, south for 1.0 h, and southwest for 2.5 h, always moving at the same speed. Realizing it is going to get dark soon, you head directly home. How long does it take to walk directly home if your speed stays the same as it was on every leg of the walk? ●●
32. An object's displacement is given by $\vec{r}(t) = (At + Bt^3)\hat{\imath} + (C - Dt^2)\hat{\jmath}$. (*a*) Write the expression for $\vec{v}(t)$ for this motion and the expression for $\vec{a}(t)$. (*b*) Using the values $A = 2.0$ m/s, $B = 0.10$ m/s^3, $C = 5.0$ m, and $D = 0.20$ m/s^2, plot the object's position on a graph that has x as the horizontal axis and y as the vertical axis for instants $t = 0$, 1.0 s, 2.0 s, and 3.0 s. At these positions, draw the velocity and acceleration vectors. ●●
33. Translate the position function $\vec{r}(t) = A\cos(\omega t)\,\hat{\imath} + A\sin(\omega t)\hat{\jmath}$ into polar coordinates, where A and ω are constants. ●●
34. A plane travels in a straight line from position A to position B in 65 min, moving at an average speed of 400 km/h. In a car traveling from A to B, the driver finds that the trip is 600 km long by the route he is forced to take, which goes straight south for a certain distance and then straight west for a longer distance. At what angle south of west does the plane travel? ●●
35. A runner is training on a perfectly circular track with radius 85 m. They run at 7.0 m/s for 1.0 minute. What are the athlete's (*a*) displacement, (*b*) average velocity, and (*c*) magnitude of average velocity? ●●
36. (*a*) In a Cartesian coordinate system that has axes x and y, the coordinates of a certain point P are (x, y). What are the coordinates of P in a Cartesian coordinate system that has axes x' and y' if the origins coincide but the x' axis is tipped above the x axis by an angle φ? (*b*) If the x and y coordinates of P are (5.0 m, 2.0 m) and $\varphi = 30°$, determine (x', y'). ●●●
37. (*a*) Suppose you have two arrows of equal length on a tabletop. If you can move them to point in any direction but they must remain on the tabletop, how many distinct patterns are possible such that the arrows, treated as vectors, sum to zero? [Note: If a pattern cannot be rotated on the tabletop to match another pattern in your list, it is a distinct pattern.] (*b*) Repeat part *a* for three identical arrows, assuming the angle between any adjacent pair must be equal. (*c*) Repeat for four arrows, keeping the angle between neighboring arrows the same throughout the pattern. (*d*) What is the relationship between the number of arrows (vectors) and the number of distinct patterns? ●●●

10.7 Projectile motion in two dimensions

38. An egg is thrown horizontally out of a window 1.5 m off the ground with an initial speed of 8.5 m/s. How far from the building does the egg hit the ground? ●
39. Which is the best representation in Figure P10.39 of the trajectory of a cantaloupe thrown horizontally off a bridge? What is wrong with the other paths? ●

Figure P10.39



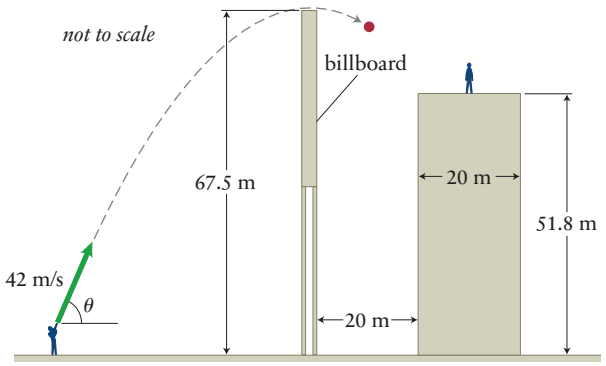
40. A bullet is fired horizontally from a high-powered rifle. At the same instant, a bullet that was resting on top of the rifle falls off. Which bullet hits the ground first? ●
41. A rifle is aimed horizontally at a target 100 m away, and the bullet leaves the rifle barrel at 650 m/s. If the gun is aimed right at the bull's-eye, by how much does the bullet miss the center? ●
42. On a rifle that has a telescopic sight, the telescope is usually not parallel to the barrel of the rifle. The angle the telescope makes with the barrel has to be adjusted for the distance to the target. Explain why. ●●
43. A ball rolls off a 0.65-m high table and lands on the floor. The speed of the ball as it hits the floor is 4.6 m/s. (*a*) How fast was the ball rolling as it left the table? (*b*) What is the horizontal distance from the edge of the table to the ball's landing point? ●●
44. A package is dropped from a helicopter traveling at 15 m/s (horizontally) at an altitude of 200 m, but the parachute attached to the package fails to open. (*a*) How long does it take for the package to hit ground? (*b*) How far does the package travel horizontally before it lands? (*c*) What is the speed of the package just before it lands? ●●
45. The velocity of an object is given in SI units by $\vec{v} = (at - bt^2)\hat{\imath} + c\hat{\jmath}$, with $a = 14$ m/s^2, $b = 10$ m/s^3, and $c = 22$ m/s. (*a*) If the initial position of the object at $t = 0$ is at the origin ($x_i = y_i = 0$), when, if ever, does the object return to the origin? (*b*) When, if ever, is the velocity zero? (*c*) When, if ever, is the acceleration zero? ●●
46. A cannon launches two shells at the same speed, one at 55° above horizontal and one at 35° above horizontal. Which shell, if either, has the longer range? Which shell, if either, is in the air longer? Assume level ground and ignore air resistance. ●●
47. A golf ball is hit from the tee and travels above level ground. Accounting for air resistance, where is the horizontal location of the peak of the flight: at a position that is less than half the range, at a position that is half the range, or at a position that is more than half the range? ●●
48. A cannon fires a shell at an angle such that the shell's initial velocity has a horizontal component of 20 m/s and a vertical component of 35 m/s. Draw the approximate location of the shell at the instants 0, 1.0 s, 2.0 s, 3.0 s, and 4.0 s. At each location, draw the horizontal and vertical components of the velocity. ●●

49. Taking air resistance into account, draw the acceleration vector of a golf ball at five positions along its trajectory from tee to green. Assume for simplicity that the force of air resistance has a constant magnitude. ••

50. How far does a fastball released from the pitcher's hand at a speed of 42 m/s fall as it travels from pitcher to batter, a distance of 18.4 m? (Your answer gives you a good idea of why the pitcher stands on a mound of dirt.) ••

51. The fish in Figure P10.51, peering from just below the water surface, spits a drop of water at the grasshopper and knocks it into the water. The grasshopper's initial position is 0.45 m above the water surface and 0.25 m horizontally away from the fish's mouth. If the launch angle of the drop is 63° with respect to the water surface, how fast is the drop moving when it leaves the fish's mouth? ••

Figure P10.51



52. A burglar evading the police is running as fast as he can on a building's flat rooftop. At the edge, he sees another flat rooftop across an alley. The horizontal distance across the alley is 8.0 m, the other rooftop is 3.0 m lower than the one on which the burglar is standing, and he can run the 50-m dash in 5.6 s. Can he make the leap when moving at full speed? ••

53. You throw a ball at an angle of 30° above the horizontal at a wall 20 m away. The ball's initial speed is 15 m/s, and it leaves your hand at a height of 1.5 m above the ground. (*a*) How long does the ball take to get to the wall? (*b*) How high up on the wall does it hit? (*c*) What are the horizontal and vertical components of its velocity as it hits the wall? (*d*) When it hits, has it already passed the highest point in its trajectory? ••

54. Figure P10.54 shows a friend standing on the roof of a building that is 51.8 m tall. The roof is square and measures 20 m on a side. You want to shoot a paintball so that it lands on the roof and startles your friend, using a gun that shoots paintballs at a muzzle speed of 42 m/s. The only problem is a slim billboard 67.5 m high between you and the roof, 20 m in front of the building. You position yourself in front of the billboard such that when you hold the gun 1.5 m above the ground and fire, the paintball just barely gets over the billboard at the highest point in its trajectory. (*a*) At what angle θ above the horizontal do you need to shoot the ball to clear the billboard? (*b*) What is your horizontal distance from the billboard? (*c*) How long does the paintball take to move from the highest point in its trajectory to the height of the roof? (*d*) Does the ball strike the roof? (*e*) What is the speed of the ball when it strikes? •••

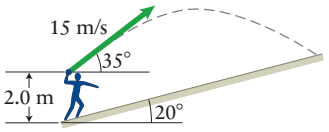


Figure P10.54

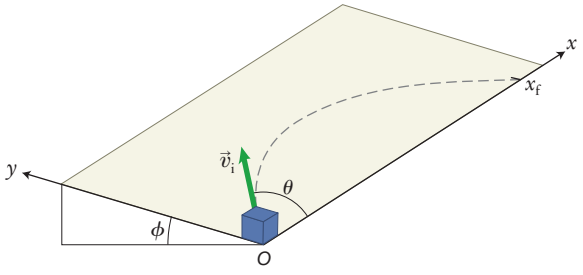
55. You throw a textbook to a friend who is at their dormitory window 2.2 m above you. You are standing 4.0 m away from the building and your throw is perfectly made such that when the book arrives at your friend it is travelling exactly horizontally. What is the book's velocity vector as it leaves your hand? ••



56. You are standing on a slope of 20° to the horizontal and are going to throw a ball at 15 m/s up the incline (Figure P10.56). If you throw the ball at 35° with respect to the horizontal, at what distance up the incline from your feet does it land? Assume the ball leaves your hand directly overhead, 2.0 m above the slope. •••

Figure P10.56

57. A block of inertia m sits at the origin of an xy coordinate system aligned along an incline that makes an angle ϕ with respect to the horizontal (Figure P10.57). You launch the block up the incline, with initial speed v_i directed at an angle θ with respect to the x axis in the plane of the incline. (*a*) What are the magnitude and direction of the block's acceleration expressed in terms of the indicated coordinate system? (*b*) Derive an expression for the block's velocity as a function of time, expressed in unit vector notation for the indicated coordinate system. (*c*) What is the maximum value of the block's displacement Δy along the y axis? (*d*) What is the block's maximum displacement Δx along the x axis? Ignore friction. •••

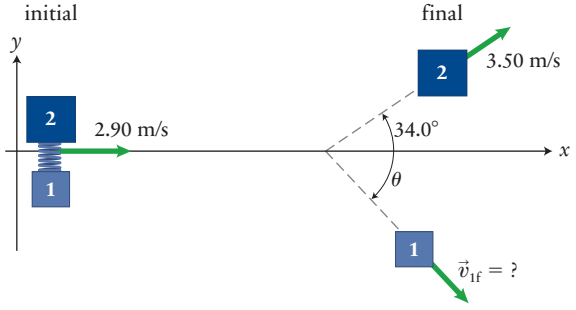


Figure P10.57

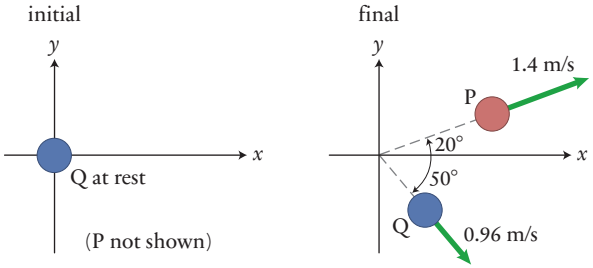
10.8 Collisions and momentum in two dimensions



58. A shell explodes prematurely in midair. What happens to the center of mass of the shell? •
59. A cue ball of inertia m is given a speed v before it collides elastically with a full rack of 15 stationary balls in a game of pool. If each of the 16 balls has an inertia m, what are (*a*) the *average* speed of each ball after they fly apart and (*b*) the *average* momentum of each ball after they fly apart? ••
60. Object A, at rest on a low-friction table, is struck a glancing blow by object B. Show that, if the collision is elastic and the two objects have equal inertias, the angle between the final directions of motion of the two objects is 90°. ••
61. Disk 1 (of inertia m) slides with speed 1.0 m/s across a low-friction surface and collides with disk 2 (of inertia $2m$) originally at rest. Disk 1 is observed to bounce off at an angle of 15° to its original line of motion, while disk 2 moves away from the impact at an angle of 55°. (*a*) Calculate the unknown final speed of each disk. (*b*) Is this collision elastic? ••
62. A system of inertia 0.50 kg consists of a spring gun attached to a cart. The system is at rest on a horizontal low-friction track. A 0.050-kg projectile is loaded into the gun, then launched at an angle of 40° with respect to the horizontal plane. With what speed does the cart recoil if the projectile rises 2.0 m at its maximum height? ••
63. A spring ($k = 3800$ N/m) is compressed between two blocks: block 1 of inertia 1.40 kg and block 2 of inertia 2.00 kg. The combination is held together by a string (not shown in Figure P10.63). The combination slides *without spinning* across low-friction ice at 2.90 m/s when suddenly the string breaks, allowing the spring to expand and the blocks to separate. Afterward, the 2.00-kg block is observed to move at a 34.0° angle to its initial line of motion at a speed of 3.50 m/s, while the smaller block moves off at an unknown speed and angle. Neither block is rotating after the separation, and you can ignore the inertias of the spring and the string relative to those of the blocks. (*a*) Determine the velocity of block 1 after the separation. (*b*) Determine the original compression of the spring, $y - y_0$, from its relaxed length y. ••

Figure P10.63

64. Disk P (inertia 0.40 kg) moves at an unknown velocity across a low-friction horizontal surface and collides with disk Q (inertia 0.70 kg), which is initially at rest. After the collision, the two (now slightly dented) disks move apart without spinning. Velocity information is provided in the initial and final top-view diagrams (Figure P10.64). (*a*) What was the initial velocity of disk P? (*b*) What fraction of the initial kinetic energy is converted during the collision? •••

Figure P10.64

10.9 Work as the product of two vectors

65. If the angle between vectors $\vec{A}$ and $\vec{B}$ is 110° and if $A = 1.7$ N and $B = 2.0$ m, what is the value of $\vec{A} \cdot \vec{B}$? •
66. Vector $\vec{A}$ has a magnitude of 3.5 units, and vector $\vec{B}$ has a magnitude of 11 units. If the value of $\vec{A} \cdot \vec{B}$ is 22.4 units squared, what is the angle between $\vec{A}$ and $\vec{B}$? •
67. Vector $\vec{A}$ points in the negative y direction and has a magnitude of 5.0 units. Vector $\vec{B}$ has a positive x component of 3.0 units and a negative y component of 7.0 units. (*a*) What is the angle between the vectors? (*b*) Determine $\vec{A} \cdot \vec{B}$. •
68. A force $\vec{F} = F_x\hat{\imath} + F_y\hat{\jmath}$ with $F_x = 50$ N and $F_y = 12$ N is exerted on a particle as the particle moves along the x axis from $x = 1.0$ m to $x = -5.0$ m. (*a*) Determine the work done by the force on the particle. (*b*) What is the angle between the force and the particle's displacement? ••
69. A force $\vec{F} = F_x\hat{\imath} + F_y\hat{\jmath}$ with $F_x = 3.0$ N and $F_y = 2.0$ N is exerted on a particle that undergoes a displacement $\vec{D} = D_x\hat{\imath} + D_y\hat{\jmath}$ with $D_x = 2.0$ m and $D_y = -2.0$ m. (*a*) Determine the work done by the force on the particle. (*b*) What is the angle between $\vec{F}$ and $\vec{D}$? ••
70. Calculate $\vec{C} \cdot (\vec{B} - \vec{A})$ if $\vec{A} = 3.0\hat{\imath} + 2.0\hat{\jmath}$, $\vec{B} = 1.0\hat{\imath} - 1.0\hat{\jmath}$, and $\vec{C} = 2.0\hat{\imath} + 2.0\hat{\jmath}$. ••
71. You are playing with a toy in which a marble launched by a spring rolls along a track full of loop-the-loops and curves with almost no energy dissipated. You want the marble to have a speed of 0.70 m/s when it arrives at the top of a loop that is 0.30 m higher than the marble's position when you launch it. (*a*) What initial speed must the marble have? (*b*) If the marble has an inertia of 5.0 g and the spring has a spring constant of 13 N/m, how far back do you need to pull the spring on the level launching chute to get the marble to have this initial speed? ••
72. A traveller walks 30 m along a train platform, dragging their suitcase behind them using a strap attached to the top. The traveller's hand is 0.25 m above the top of the suitcase, and the 0.80-m long strap maintains a tension of 120 N as the suitcase is dragged. How much work does the strap do on the suitcase? ••
73. A 20-kg boy slides down a smooth, snow-covered hill on a plastic disk. The hill is at a 10° angle to the horizontal, and the slope is 50 m long. (*a*) If the boy starts from rest, what is his speed at the bottom of the hill? (*b*) His sister then hauls him and the disk from the bottom to the top by means of a rope attached to the disk. What average force must she exert on the rope if the boy is going 0.50 m/s when he reaches the top? ••

74. Two children pull a third child on a tricycle by means of two ropes tied to the handlebars. The combined inertia of the child and tricycle is 35 kg. One child pulls with a constant force of 100 N directed to the right of the straight-ahead direction at an angle of 45°. (*a*) If the second child pulls with a force of 80 N, at what angle to the left of the straight-ahead direction must he pull to make the tricycle move straight ahead? (*b*) With the second child pulling at the angle you calculated in part *a*, what is the acceleration of the tricycle? (*c*) What is the work done on the tricycle by the two ropes if the children pull constantly like this while the tricycle moves 2.0 m? ●●

75. If $\vec{A} = A_x\hat{\imath} + A_y\hat{\jmath}$ and $\vec{B} = B_x\hat{\imath} + B_y\hat{\jmath}$, show that $\vec{A}\cdot\vec{B} = A_xB_x + A_yB_y$. (You may wish to use the fact that the scalar product satisfies the distributive property: $\vec{a}\cdot(\vec{b}+\vec{c}) = \vec{a}\cdot\vec{b} + \vec{a}\cdot\vec{c}$.) ●●●

76. Starting from rest, an intern pushes a 45-kg gurney 40 m down the hall with a constant force of 80 N directed downward at an angle of 35° with respect to the horizontal. (*a*) What is the work done by the intern on the gurney during the 15-m trip? (*b*) How fast is the gurney going when it has moved 15 m? (*c*) How much time elapses during the 15-m journey? Ignore friction. ●●●

77. You know you can provide 500 W of power to move large objects. You need to move a 50-kg safe up to a storage loft, 10 m above the floor. (*a*) With what average speed can you pull the safe straight up? (*b*) How much work do you do on the safe in doing this? (*c*) With what average speed can you pull the safe up a 30° incline? (*d*) How much work do you do on the safe moving if you slide it up the incline to the loft? ●●●

10.10 Coefficients of friction

78. A bartender gives a full mug of beer an initial speed v_{full}, and the mug stops in front of a patron sitting at the end of the bar. This patron later asks for a mug only half full. The bartender stands at the same position as when she sent the full mug to the patron and gives the mug an initial speed v_{half}. If the mug is to again stop in front of the patron, which is true: $v_{\text{half}} < v_{\text{full}}$, $v_{\text{half}} = v_{\text{full}}$, or $v_{\text{half}} > v_{\text{full}}$? ●

79. The heavy crate in Figure P10.79 has plastic skid plates on its bottom surface and a tilted handle attached to one side. Which is easier: pushing the crate or pulling it? Assume your force is exerted along the incline of the handle in either case, and consider friction. ●

Figure P10.79

80. You have lost your skateboard, so you choose to walk around the various sections of the local skate park. The coefficient of static friction between your shoes and the concrete surface is 0.53. What is the angle of the steepest ramp you can stand on without slipping? ●

81. Moving a 51-kg box across a floor, you discover that it takes 200 N of force to get the box moving, and then 100 N keeps it moving at constant speed. What are the coefficients of static and kinetic friction between box and floor? ●

82. Starting from rest, you push your physics book horizontally along a table. Plot the magnitude of the force of friction exerted on the book as a function of the magnitude of the force you exert. Include both static and kinetic cases in the range of force magnitudes you consider. ●●

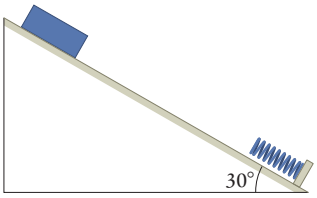
83. A resort uses a rope to pull a 55-kg skier up a 40° slope at constant speed for 100 m. (*a*) Calculate the tension in the rope if the coefficient of kinetic friction between snow and skis is $\mu_k = 0.20$. (*b*) How much work does the rope do on the skier? (If you did Problem 22, you might be interested in comparing your answers here with those in Problem 22.) ●●

84. When moving on level ground, cross-country skiers slide their skis along the snow surface to stay moving. The coefficients of friction for a given set of skis and given snow conditions can be modified by various types of waxes. In order to move across the snow as fast as possible, (*a*) should you choose a wax that makes the coefficient of static friction between skis and snow as high as possible or as low as possible? (*b*) Should you choose a wax that makes the coefficient of kinetic friction between these two surfaces as high as possible or as low as possible? ●●

85. A janitor is pushing an 11-kg trashcan across a level floor at constant speed. The coefficient of friction between can and floor is 0.10. (*a*) If the janitor is pushing horizontally, what is the magnitude of the force he exerts on the can? (*b*) If he pushes at an angle of 30° down from the horizontal, what must the magnitude of his pushing force be to keep the can moving at constant speed? ●●

86. A hockey puck on the ice starts out moving at 10.50 m/s but after 40.00 m has slowed to 10.39 m/s. (*a*) What is the coefficient of kinetic friction between ice and puck? (*b*) On this same ice, what is the speed after 40.00 m when an identical puck is glued on top of the first one and the combination again starts at 10.50 m/s? ●●

87. The coefficient of kinetic friction between tires and dry pavement is about 0.80. Assume that while traveling at 27 m/s you lock your brakes and as a result the only horizontal force on the car is the frictional one. (*a*) How many seconds does it take you to bring your car to a stop? (*b*) If the road is wet and the coefficient of kinetic friction between tires and pavement is only 0.25, how long does it take? (*c*) How far do you travel in this time interval? ●●



88. A block of inertia m is placed on an inclined plane that makes an angle θ with the horizontal. The block is given a shove directly up the plane so that it has initial speed v, and the coefficient of kinetic friction between the block and the plane surface is μ_k. (*a*) How far up the plane does the block travel before it stops? (*b*) If the coefficient of static friction between block and surface is μ_s, what maximum value of θ allows the block to come to a halt somewhere on the plane and not slide back down? ●●

89. A 1.0-kg block on a horizontal tabletop is pushed against the free end of a spring (the other end is attached to a wall) until the spring is compressed 0.20 m from its relaxed length. The spring constant is $k = 100$ N/m, and the coefficient of kinetic friction between block and tabletop is 0.20. When the block is released from being held against the compressed spring, how far does the block travel before coming to rest? ●●

90. A man exerts a constant force to pull a 50-kg box across a floor at constant speed. He exerts this force by attaching a rope to the box and pulling so that the rope makes a constant angle of 36.9° above the horizontal. The coefficient of kinetic friction for the box-floor interface is $\mu_k = 0.10$. What is the work done by the man as he moves the box 10 m? ••

91. An inclined plane that makes an angle of 30° with the horizontal has a spring of spring constant 4500 N/m at the bottom (Figure P10.91). A 2.2-kg block released near the top of the plane moves down the plane and compresses the spring a maximum of 0.0240 m from its relaxed length. (*a*) Ignoring any frictional effects, calculate the distance the leading edge of the block travels from the instant the block is released to the instant it briefly stops against the compressed spring. (*b*) Now suppose there is friction between the block and the surface of the plane, with $\mu_k = 0.10$. If the block is again placed somewhere on the plane and allowed to slide down and compress the spring by the same 0.0240 m, how far does the leading edge of the block travel now? ••

Figure P10.91

92. You push down on a book of inertia m resting on a table with a force directed at an angle θ away from vertical. The coefficient of static friction between book and table is μ_s. If θ is not larger than some critical value, you cannot get the book to slide no matter how hard you push. What is that critical value? •••

93. You push a 2.0-kg block up a ramp by exerting a 100-N force directed parallel to the ramp, which is at a 30° angle to the horizontal. (*a*) Ignoring any effects due to friction, calculate the block's speed when you have pushed it 2.0 m if its upward speed when you began pushing was 2.0 m/s. (*b*) Now consider friction. If the coefficient of kinetic friction between block and ramp is 0.25, what is the block's speed after you have pushed it 2.0 m? (*c*) With this value of μ_k, how much farther up the ramp does the block move once you stop pushing after the 2.0 m? •••

94. A platform that rolls on wheels and has inertia m_p is attached to a wall by a horizontal spring of spring constant k. A load of inertia m_ℓ sits on the platform, and the coefficient of static friction between platform and load is μ_s. If you pull the platform away from the wall so that the spring is stretched a distance x from its relaxed length and then let go, the platform-spring combination bounces back and forth. (*a*) At what position(s) in the motion is the load most likely to fall off? (*b*) If you want the load to stay in place held only by friction, what is the maximum distance x_{max} you can stretch the spring from its relaxed length and have the load stay on when you release the platform-spring combination? •••

95. You have to specify the power output of a motor for a ski tow rope that will carry 20 skiers at a time. The grade of the ski slope is 32° above horizontal, and the average coefficient of kinetic friction between skis and snow is 0.12. If the tow speed is to be 3.0 m/s and each skier has an inertia of 60 kg (a reasonable average value), what must the minimum power output of the motor be? •••

96. A spring of spring constant k is attached to a support at the bottom of a ramp that makes an angle θ with the horizontal. A block of inertia m is pressed against the free end of the spring until the spring is compressed a distance d from its relaxed length. Call this position A. The block is then released and moves up the ramp until coming to rest at position B. The surface is rough from position A for a distance $2d$ up the ramp, and over this distance the coefficient of kinetic friction for the two surfaces is μ. Friction is negligible elsewhere. What is the distance from A to B? •••

Additional Problems

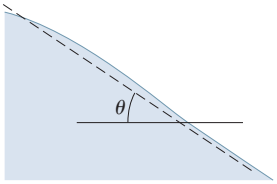
97. A sports car skids to a stop, leaving skid marks 290 m long. If the coefficient of kinetic friction between tires and pavement is 0.50, how fast was the car going before the skid? •

98. If you were to throw a penny horizontally as hard as you could from the top floor of the Empire State Building, about how far from the base would it land? •

99. Plot the range of a projectile as a function of the launch angle above horizontal. •

100. Watering the garden, you need to have the water reach farther and instinctively raise the hose nozzle to increase the range of the water stream. You realize that increasing the angle the nozzle makes with the ground increases the time interval during which the water is in flight, thereby letting the horizontal motion continue longer. This maneuver works only up to a point, however. Why? ••

101. A particle initially at the origin of an xy coordinate system and having an initial velocity of $(40\ \text{m/s})\hat{\imath}$ experiences a constant acceleration of $\vec{a} = a_x\hat{\imath} + a_y\hat{\jmath}$, with $a_x = -1.0\ \text{m/s}^2$ and $a_y = -0.50\ \text{m/s}^2$. (*a*) What is the maximum x coordinate of the particle's motion? (*b*) What is its velocity when it reaches this position? (*c*) What is its y coordinate at this instant? ••



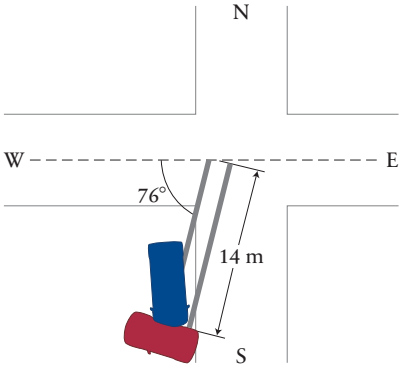
102. Describe the properties of two vectors for which (*a*) $\vec{A} + \vec{B} = \vec{A} - \vec{B}$ and (*b*) $|\vec{A}| + |\vec{B}| = |\vec{A} + \vec{B}|$. ••

103. Three forces are exerted on a 2.00-kg block initially at rest on a slippery surface: a 100-N force directed along the positive x axis, a 50.0-N force that makes an angle of 30.0° with the positive x axis, and a 144-N force that makes an angle of 190° with the positive x axis. (Both angles are measured as viewed from above.) (*a*) What is the vector sum of the forces exerted on the block? (*b*) What is the work done on the block in 10.0 s? ••

104. An airline pilot begins a trip to Duluth from an airport located 1500 km south of Duluth. Her air speed is 260 m/s, but a wind blows from west to east at 40 m/s that takes her off course if she flies directly north. She has the choice of heading slightly westward so that the wind causes her to end up at Duluth or heading due north until she reaches a position directly east of Duluth and then heading west into the wind to Duluth. Which route takes a shorter time interval? ••

105. The coefficient of static friction between layers of snow is 3.7 under ideal conditions. What is the steepest angle a snow field can form (θ in Figure P10.105) before there is an avalanche? ●●

Figure P10.105



106. Having seen in Example 10.6 that there is a simple expression for the horizontal range of a projectile across level ground, you begin to wonder whether there is an expression for the horizontal range of an object that is thrown with initial speed v_i at an angle θ above the horizontal from the edge of a cliff of height h. ●●● CR

107. You have inherited property in Vermont that would make an excellent ski resort. One of the slopes has a cliff on the other side of the hill, and this gives you a money-saving idea. Instead of a chair lift or motorized tow rope, you decide to attach a pulley to the top of the cliff and then drape the tow rope over the pulley, with one end of the rope temporarily secured at the base of the ski slope and a counterweight attached to the end that hangs over the pulley at the cliff edge. The plan is to release the rope and pull two skiers (with the inertia for the pair kept between 100 kg and 200 kg) up the 400-m slope, which has an incline angle of 35° and a coefficient of kinetic friction between skis and snow no larger than 0.10. You guess that customers get nervous if they move faster than 5.0 m/s, and you wonder if a single counterweight can satisfy these constraints. ●●● CR

108. You are investigating a rural accident. The evidence at the scene suggests that a car was traveling west when struck by a van traveling south. The crushed vehicles stuck together, then came to rest at the end of skid marks of length 14 m along a 76° line as shown in Figure P10.108. (The figure is a top view.) The ground is flat with no curbs, and you estimate a coefficient of kinetic friction $\mu_k = 0.70$ for the crushed vehicles along the path of the skid. You look up the inertias of these model vehicles and find that $m_c = 1400$ kg and $m_v = 6500$ kg. You know that the speed limit is 35 mi/h on both roads, which allows you to decide about driver citations. ●●● CR

Figure P10.108

109. A 0.45-kg soccer ball is kicked at an angle θ above the ground with initial speed v_i. (*a*) Determine the height of the ball as a function of the horizontal distance it travels down the field. (*b*) For $\theta = 30°$, what initial speed must the ball have in order to land 48 m from where it is kicked? (*c*) If the foot is in contact with the ball for 0.15 s, what is the average force exerted by the foot on the ball? ●●●

110. A ballistic pendulum is a device for measuring bullet speeds. One of the simplest versions consists of a block of wood hanging from two long cords. (Two cords are used so that the bottom face of the block remains parallel to the floor as the block swings upward.) A 9.5-g bullet is fired into a ballistic pendulum in which the block has an inertia of 5.0 kg, and the block rises 60 mm above its initial position. (*a*) What is the speed of the bullet just before it hits the block? (*b*) How much energy is dissipated in the collision? What forms does this dissipated energy take? ●●●

111. A 0.010-kg bullet traveling at 300 m/s hits a 2.0-kg ballistic pendulum like the one described in Problem 110. However, the block is not thick enough for this bullet, and the bullet passes through the block, exiting with one-third of its original speed. How high above its original position does the block rise? ●●●

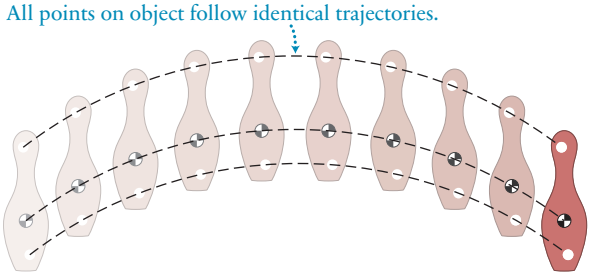
Motion in a Circle

11.1 Circular motion at constant speed
11.2 Forces and circular motion
11.3 Rotational inertia

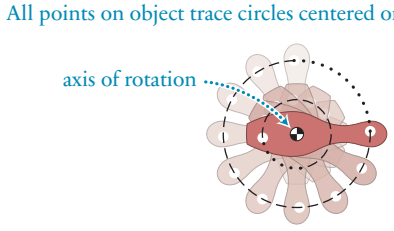
11.4 Rotational kinematics
11.5 Angular momentum
11.6 Rotational inertia of extended objects

CONCEPTS



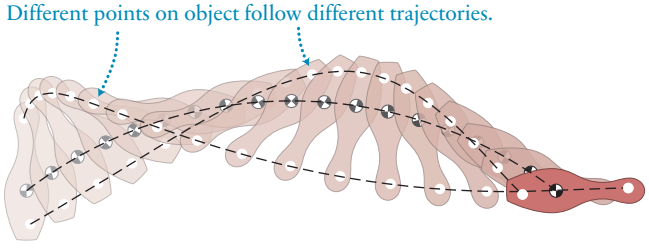
QUANTITATIVE TOOLS

The motion we have been dealing with so far in this text is called **translational motion** (Figure 11.1*a*). This type of motion involves no change in an object's orientation; all the particles in the object move along identical parallel trajectories. During **rotational motion,** which we begin to study in this chapter, the orientation of the object changes, and the particles in an object follow different circular paths centered on a straight line called the *axis of rotation* (Figure 11.1*b*). Generally, the motion of rigid objects is a combination of these two types of motion (Figure 11.1*c*). (Recall that when forces act on a rigid object, we can ignore deformation.) As we shall see in Chapter 12 this combined motion can be broken down into translational and rotational parts that can be analyzed separately. Because we already know how to describe translational motion, knowing how to describe rotational motion will complete our description of the motion of rigid objects.



As Figure 11.1*b* shows, each particle in a rotating object traces out a circular path, moving in what we call *circular motion*. We therefore begin our analysis of rotational motion by describing circular motion. Circular motion occurs all around us. A speck of dust stuck to a spinning top, a stone being whirled around on a string, a person on a Ferris wheel—all travel along the perimeter of a circle, repeating their motion over and over. Circular motion takes place in a plane, and so in principle we have already developed all the tools required to describe it. To describe circular and rotational motion we shall follow an approach that is analogous to the one we followed for the description of translational motion. Exploiting this analogy, we can then use the same results and insights gained in earlier chapters to introduce a third conservation law.

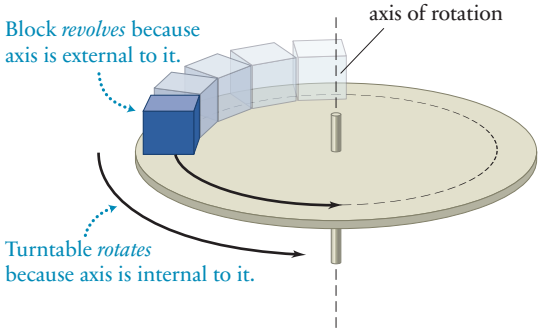
Figure 11.1 Translational and rotational motion of a rigid object.



(*a*) Translational motion

(*b*) Rotational motion

(*c*) Combined translation and rotation



11.1 Circular motion at constant speed

Figure 11.2 shows two examples of circular motion: a block dragged along a circle by a rotating turntable and a puck constrained by a string to move in a circle. The block and puck are said to *revolve* around the vertical axis through the center of each circular path. Note that the axis about which they revolve is external to the block and puck and perpendicular to the plane of rotation. This is the definition of *revolve*—to move in circular motion around an *external* center. Objects that turn about an *internal* axis, such as the turntable in Figure 11.2*a*, are said to *rotate*. These two types of motion are closely related because a rotating object can be considered as a system of an enormous number of particles, each revolving around the axis of rotation.

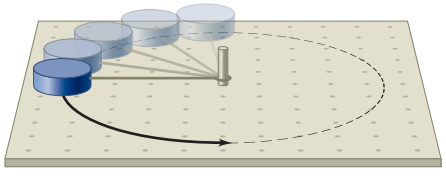


Figure 11.3 shows an overhead view of a puck moving counterclockwise along the arc of a circle. The puck's average velocity points in the same direction as the puck's displacement $\Delta\vec{r}$, which points from the puck's initial position to its final position. As we consider the

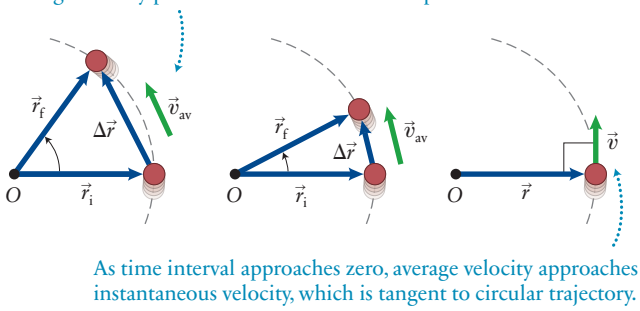
Figure 11.2 Examples of circular motion.

(*a*) Block revolves on rotating turntable



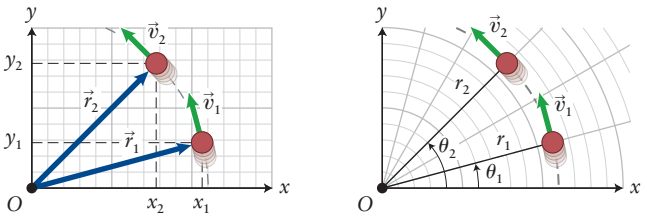
(*b*) Tethered puck revolves on air table

CONCEPTS

Figure 11.3 Average and instantaneous velocity for an object in circular motion.

motion for increasingly smaller time intervals, the angle between the position vectors $\vec{r}_i$ and $\vec{r}_f$ measured from the center of the circular trajectory approaches zero and $\Delta\vec{r}$ becomes tangent to the circular trajectory. This is true all along the trajectory, and so we can say:

> **The instantaneous velocity $\vec{v}$ of an object in circular motion is always perpendicular to the object's position $\vec{r}$ measured from the center of the circular trajectory.**

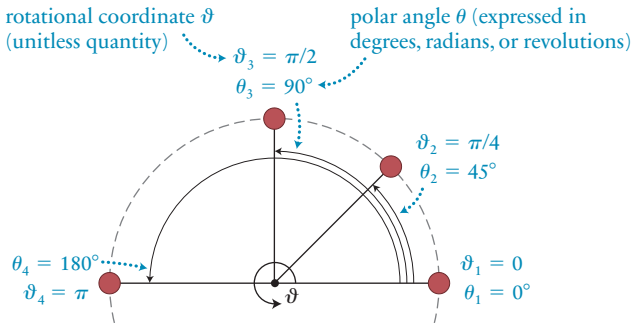


In the first part of this chapter, we study only objects in **circular motion at constant speed;** that is to say, the magnitude of their instantaneous velocity doesn't change.

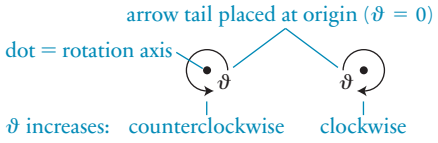
Because the motion lies entirely in a plane, we can use Cartesian coordinates to describe the puck's position and velocity at any instant. In **Figure 11.4a**, for example, the puck's position is specified by (x_1, y_1) at instant t_1 and by (x_2, y_2) at instant t_2. However, because the magnitude of the position vector $\vec{r}$ is always equal to the radius of the circle, we can also give the magnitude r and the direction of this vector to specify the puck's position, as indicated by the angles θ_1 and θ_2 in Figure 11.4*b*. To specify the direction, we define the puck's **rotational coordinate,** which is a unitless number that increases by 2π for each circle completed by the revolving puck.* The rotational coordinate is denoted by the Greek letter ϑ (script theta); for example, $\vartheta = \pi$ refers to the position of the puck half a revolution after starting from the origin. The rotational coordinate is related to *polar angle* θ as shown in **Figure 11.5a**. Unlike the rotational coordinate, however, the polar angle is not a unitless number but rather expressed in units of revolutions, degrees, or radians.

To measure ϑ we need to choose a direction of increasing ϑ and a zero, just as we need to specify a direction of increasing x and an origin to measure position along an axis. We shall indicate our choice of rotational coordinate system, which will generally be dictated by the motion under consideration, by drawing a curved arrow around the axis of rotation, as shown in Figure 11.5*b*.

Figure 11.4 The position of an object in circular motion can be given in Cartesian or polar coordinates.



(*a*) Cartesian (x, y) coordinates (*b*) Polar (r, θ) coordinates



*The adjective *rotational* is used for both rotation and revolution.

Figure 11.5 The rotational coordinate specifies the location of an object on a circle.

(*a*) Relationship between rotational coordinate and polar angle

(*b*) Symbol used in this text to specify rotational coordinate system

EXERCISE 11.1 Rotational coordinates

Determine the rotational coordinate of the following objects for the indicated choices of rotational coordinate system. (*a*) The tip of the hour hand of a clock at 4:30 p.m., when zero is at noon on the same day and ϑ increases in the clockwise direction. (*b*) A faucet after being turned 3/4 of a turn in a clockwise direction, starting from zero and with ϑ increasing in the counterclockwise direction. (*c*) The object in Figure 11.4 if $\theta = 78.3°$, when zero is at $\theta = 0°$ and ϑ increases in the counterclockwise direction.

SOLUTION (*a*) The angle between noon and 4:30 p.m. is 135°, which is $(135°)/(360°) = 0.375$ of one revolution. Because the rotation takes place in the positive direction and because ϑ increases by 2π for each revolution, $\vartheta = (2\pi)(+0.375) = +2.36$. Note that there are no units because ϑ is a unitless quantity. ✔

(*b*) $\vartheta = (2\pi)(-3/4) = -\frac{3}{2}\pi$. ✔

(*c*) $\vartheta = (2\pi)(+78.3°)/(360°) = +1.37$. ✔

CONCEPTS

We shall represent the rate at which an object's rotational coordinate changes by ω_ϑ (Greek omega). The subscript ϑ indicates that the sign of this quantity depends on our choice of direction for increasing ϑ, just as the sign of v_x (the rate at which an object's x coordinate changes) depends on our choice of x axis. Indeed, just as v_x is the component of a velocity vector $\vec{v}$, ω_ϑ is a component of a *rotational velocity vector* $\vec{\omega}$, which we shall discuss in Chapter 12. For convenience we shall refer to ω_ϑ as the **rotational velocity,** although strictly speaking it is the ϑ component of $\vec{\omega}$.

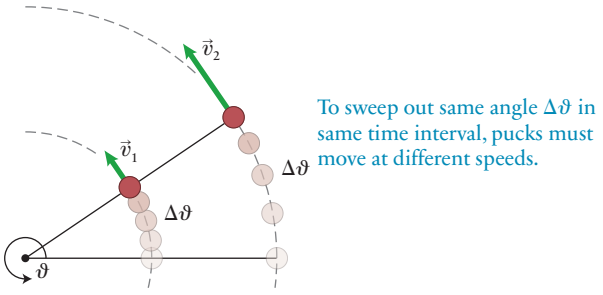
The magnitude of the rotational velocity is the **rotational speed,** which we denote by ω just as v denotes speed: $\omega = |\vec{\omega}| = |\omega_\vartheta|$. The time interval it takes an object in circular motion at constant speed to complete one revolution is called the **period** and is denoted by the letter T.

For example, if the puck in Figure 11.4 completes three revolutions in the negative ϑ direction in 2.0 s, its average rotational velocity for those three revolutions $(\Delta\vartheta = -3(2\pi) = -6\pi)$ is $\omega_{\vartheta,\text{av}} = \Delta\vartheta/\Delta t = (-6\pi)/(2.0\text{ s}) = -9.4\text{ s}^{-1}$; its average rotational speed is 9.4 s^{-1}; and its period is $T = (2.0\text{ s})/3 = 0.67$ s. Note that the units of rotational velocity and rotational speed are s^{-1} (*inverse second*).

The rotational coordinate of an object in circular motion at constant speed increases linearly with time. If it takes a puck in circular motion at constant speed 1.0 s to go from $\vartheta = 0$ to $\vartheta = +0.80$, then it also takes the puck 1.0 s to go from $\vartheta = +0.80$ to $\vartheta = +1.6$, and the object's rotational velocity is constant at $\omega_\vartheta = (+1.6 - 0.80)/(1.0\text{ s}) = +0.80\text{ s}^{-1}$.

What is the relationship between an object's speed and its rotational velocity? **Figure 11.6** shows two pucks in circular motion. The rotational coordinate of both pucks changes by the same amount $\Delta\vartheta$ during a time interval Δt, and so both have the same rotational velocity. Their speeds, however, are not the same because the puck that moves along the larger circle travels a greater distance along its trajectory than does the puck that moves along the smaller circle.

Figure 11.6 Two pucks in circular motion at constant speed can have different speeds even though their rotational velocity (the rate at which ϑ changes) is the same.



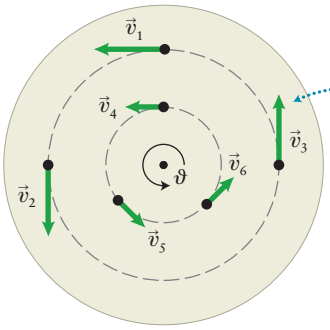


Figure 11.7 Instantaneous and rotational velocities for points on a rotating disk.

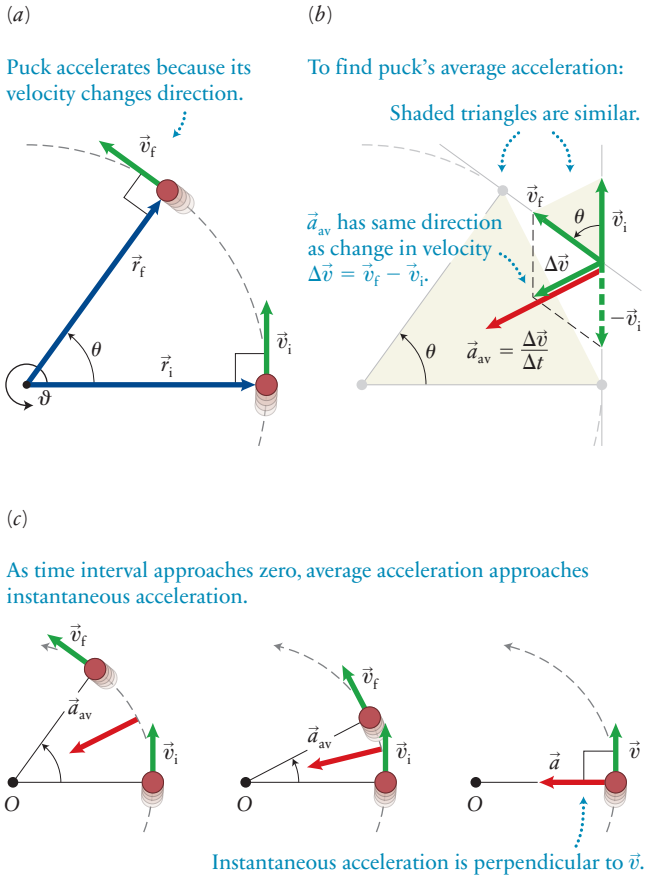
The advantage of using rotational velocity to describe rotational motion over using the ordinary velocity $\vec{v}$ becomes clear when we look at the rotating disk in **Figure 11.7**. As the velocity vectors $\vec{v}$ show, each point on the disk has a different velocity $\vec{v}$, with points farther from the axis of revolution having a greater speed than points closer to the axis. Yet all points on the disk execute the same number of revolutions per unit time, and so they all have the same rotational velocity ω_ϑ.

The velocity of an object in circular motion constantly changes direction. As **Figure 11.8*a*** shows, even though the initial and final *speeds* of the object are the same (indicated by the equal magnitudes of the velocity vectors), the vectors $\vec{v}_\text{i}$ and $\vec{v}_\text{f}$ point in different directions. The object therefore undergoes a change in velocity $\Delta\vec{v}$, which, by our definition of acceleration, means that the object accelerates.

Objects in circular motion have a nonzero acceleration even if they are moving at constant speed.

Because $\vec{r}$ and $\vec{v}$ are always perpendicular, when $\vec{r}$ rotates through an angle θ, $\vec{v}$ rotates through the same angle, which means the shaded triangles in Figure 11.8*b* are similar. To determine the change in velocity $\Delta\vec{v} = \vec{v}_\text{f} - \vec{v}_\text{i}$, we slide $\vec{v}_\text{i}$ and $\vec{v}_\text{f}$ along their tangents until their tails meet, as shown in Figure 11.8*b*, then reverse $\vec{v}_\text{i}$ (dashed vector) and add the reversed vector to $\vec{v}_\text{f}$.



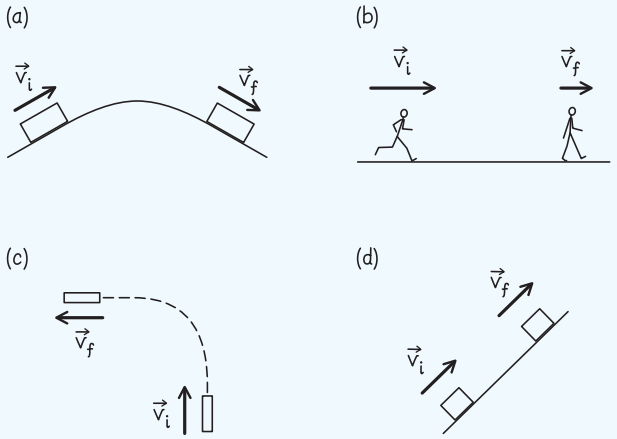
Note that the vector $\Delta\vec{v}$ we obtain in this way points toward the center of the circle. The average acceleration $\vec{a}_\text{av} \equiv \Delta\vec{v}/\Delta t$ therefore also points toward the center. As we let the time interval Δt approach zero, as in Figure 11.8*c*, we see that the (instantaneous) acceleration $\vec{a}$ is perpendicular to the velocity $\vec{v}$. Because the speed of the object is constant, the magnitude of the acceleration is constant too.

An object executing circular motion at constant speed has an acceleration of constant magnitude that is directed toward the center of its circular path.

This acceleration is called the **centripetal acceleration** (*centripetal* is Latin for "center-seeking").

CONCEPTS

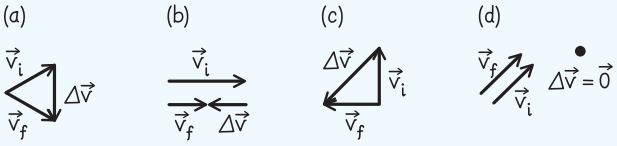
Figure 11.8 Average and instantaneous acceleration of an object in circular motion at constant speed.



In Chapter 10 we saw that the component of the acceleration parallel to an object's instantaneous velocity causes the speed of the object to change, and the perpendicular component causes the direction of the instantaneous velocity to change. For circular motion at constant speed, there is only a perpendicular component of acceleration (the *centripetal acceleration* we just described), and so only the direction of the velocity changes. Nothing pushes or pulls the object in the direction of motion, and so its speed doesn't change.

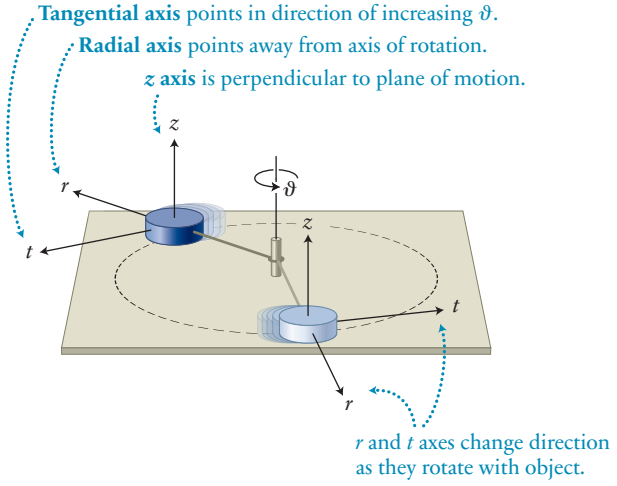
EXERCISE 11.2 Accelerations

Determine the direction of the average acceleration in each of the following situations: (*a*) A car goes over the top of a hill at constant speed. (*b*) A runner slows down after crossing a finish line on level ground. (*c*) A cyclist makes a left turn while coasting at constant speed on a horizontal road. (*d*) A roller-coaster car is pulled up a straight incline at constant speed.



SOLUTION For each situation I make a before-and-after sketch showing the initial and final velocities (**Figure 11.9**). The acceleration is nonzero if the direction of the velocity or the magnitude of the velocity changes.

Figure 11.9



The average acceleration points in the same direction as the change in velocity $\Delta\vec{v}$. To determine the direction of this vector, I draw the vectors $\vec{v}_i$ and $\vec{v}_f$ with their tails together. The change in velocity then points from the tip of $\vec{v}_i$ to the tip of $\vec{v}_f$, as shown in **Figure 11.10**. For each situation, the direction of the average acceleration is given by the direction of $\Delta\vec{v}$. ✔

Figure 11.10

To describe circular motion it is convenient to choose a coordinate system that rotates around with the object under consideration, as illustrated in **Figure 11.11**. The *radial axis*, denoted by the letter *r*, points in the direction of the radius of the circular trajectory, away from

Figure 11.11 Rotating coordinate system used to describe circular motion.

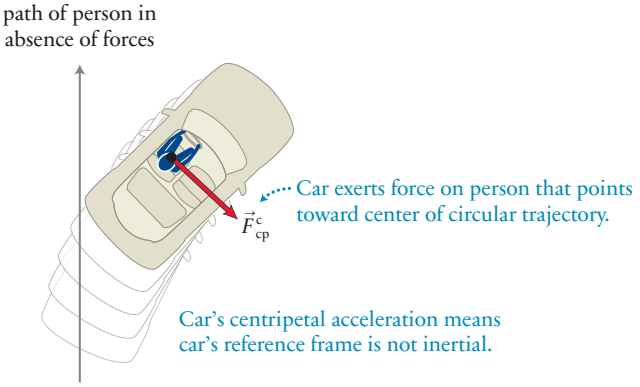
CONCEPTS

the axis of rotation. The *tangential axis*, denoted by the letter t, points in the direction of increasing ϑ, tangent to the trajectory. Because the tangent to a circle is perpendicular to the radius drawn to the point of contact of the tangent, the r and t axes are always perpendicular to each other. Often we'll need a third axis, denoted by the letter z, to describe the direction of forces exerted on the object. This axis is chosen perpendicular to the plane of motion (and therefore perpendicular to both the r and t axes).

With this choice of coordinate system, the velocity of an object executing circular motion at constant speed is always directed along the t axis and the acceleration of the object is always directed inward along the r axis.

11.1 Suppose the object in Figure 11.8 is in *accelerated* circular motion, so that $|\vec{v}_f| > |\vec{v}_i|$. In which direction does the object's average acceleration point?

11.2 Forces and circular motion



The centripetal acceleration of an object in circular motion at constant speed tells us that the vector sum of the forces exerted on the object must be directed toward the center of the circle, continuously adjusting the object's direction. Without this inward-pointing vector sum of forces, the object would move in a straight line.

An object that executes circular motion at constant speed is subject to a force (or vector sum of forces) of constant magnitude directed toward the center of the circular trajectory.

But wait! Aren't you pushed *outward* when a car makes a sharp turn? Say you are in a car that takes a right turn as illustrated in **Figure 11.12**. Even though the center of the arc describing the car's trajectory is on the right, there is no denying that your left shoulder is pressed against the left door! Don't forget, however, that because the direction of the car's velocity is changing, it has a nonzero acceleration, and so the reference frame of the car is noninertial.

In Chapter 6 we discussed how things are different in noninertial reference frames. Riding in a car that is traveling on a straight road when it makes an emergency stop, you feel as if you are being pushed forward. There is no force pushing you forward, however. Instead, the "push" you think you feel is nothing more than your body obeying the law of inertia and continuing at its original velocity. As your body tries to continue, it collides with the seat belt because the belt, being part of the car, begins to slow down. You exert a forward force on the belt, but it exerts a rearward force on you. Likewise, when a car initially traveling

Figure 11.12 As you round a curve in a car, are you pushed inward or outward?

straight ahead makes a sharp right turn, your body has a tendency to continue in a straight line. As the car begins to curve rightward, the force exerted by the left door on you forces your body into the turn. So even though you feel you are being pushed outward, an inward contact force $\vec{F}^{c}_{cp}$ is exerted by the car on you, as illustrated in Figure 11.12. The feeling of being pushed outward (leftward) arises only from the noninertial nature of the car's reference frame; in reality, your body simply tends to continue moving in a straight line. The moral is:

Avoid analyzing forces from a rotating frame of reference because such a frame is accelerating and therefore noninertial.

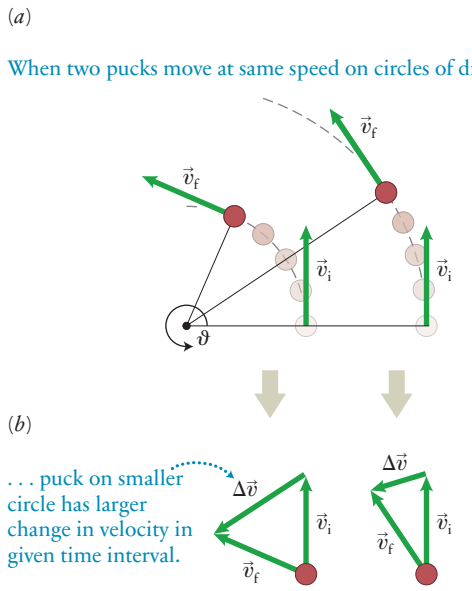
The force required to make an object go around a curve can be a push, a pull, or a combination of the two. For example, the puck in Figure 11.2*b* is pulled inward by the string; in Figure 11.12, the person is pushed inward by the car.

The magnitude of the force required to make an object move in circular motion at constant speed depends on the speed of the object and the radius of the trajectory. To see how this force depends on speed, refer to Figure 11.8*b*. By mentally increasing the magnitude of the vectors $\vec{v}_i$ and $\vec{v}_f$ (which is equivalent to increasing the speed of the revolving object), you see how the vectors $\Delta\vec{v}$ and $\vec{a}$ also get longer. Because $\Sigma\vec{F} = m\vec{a}$, an object traveling at higher speed requires a larger inward force.

To see how the inward force depends on radius, look at **Figure 11.13**, which shows two pucks moving at the same speed along circles of different radii. During a given time interval, the rotational coordinate ϑ of the puck moving along the larger circle changes less than that of the puck moving along the smaller circle. Consequently the puck on the larger circle has a smaller change in velocity and a smaller centripetal acceleration. Because force is directly

CONCEPTS

Figure 11.13 Change in velocity for pucks moving along circles of different radius.



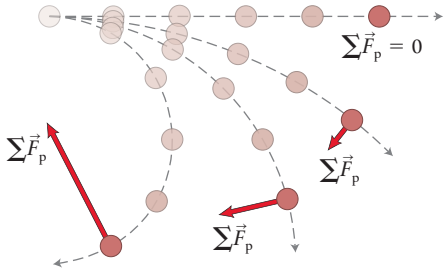


Figure 11.14 The smaller the radius, the sharper the curve and the larger the force required to make the object follow the curve.

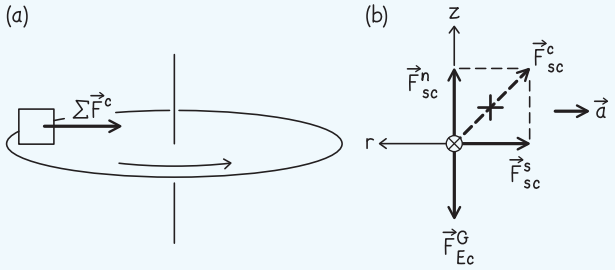
proportional to acceleration, we can say that the larger the radius, the smaller the force required to make the object go in a circle (**Figure 11.14**). As the radius approaches infinity, the object goes in a straight line and no force is required to change the direction of its velocity.



The inward force required to make an object move in circular motion increases with increasing speed and decreases with increasing radius.

EXAMPLE 11.3 Cube on turntable

A cube lies on a turntable initially rotating at constant speed. The rotational speed of the turntable is slowly increased, and at some instant the cube slides off the turntable. Explain why this happens.

1 GETTING STARTED I'm not given much information, so I begin by making a sketch of the situation (**Figure 11.15a**). As the turntable rotates, the cube executes a circular motion. My task is to explain why the cube does not remain on the turntable as the turntable rotates faster.

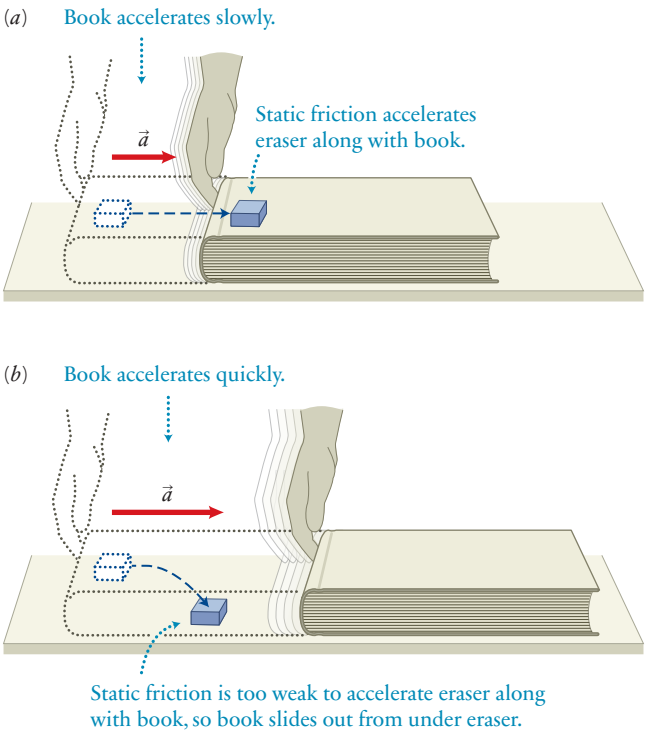
Figure 11.15

2 DEVISE PLAN Because the cube executes circular motion, it has a centripetal acceleration, and so the vector sum of the forces exerted on it must point toward the center of the turntable. I therefore need to make a free-body diagram that reflects this combination of forces and determine how the forces change as the rotational speed of the turntable increases.

3 EXECUTE PLAN To draw my free-body diagram, I must answer the question What are the forces exerted on the cube? First there is $\vec{F}^G_{Ec}$, the gravitational force exerted by Earth. This force is directed vertically downward and so cannot contribute to a force directed toward the turntable's center. The only other force exerted on the cube is $\vec{F}^c_{sc}$, the contact force exerted by the surface of the turntable. The normal component $\vec{F}^n_{sc}$ of this force must be equal in magnitude to $\vec{F}^G_{Ec}$ because the cube does not accelerate in the vertical direction. The horizontal component, which is the force of static friction $\vec{F}^s_{sc}$, is what forces the cube toward the center of its circular path. I therefore draw the free-body diagram shown in Figure 11.15*b*. Because the vertical component of the acceleration is zero, the forces in that direction add to zero. Thus the vector sum of the forces exerted on the cube equals the force of static friction.

As the rotational speed increases, the magnitude of the centripetal acceleration of the cube also increases. This means that the magnitude of the force of static friction must get larger. At some instant, this force reaches its maximum value and so can no longer increase even though the rotational speed continues to increase. Consequently, the vector sum of the forces exerted on the cube is no longer large enough to give it the centripetal acceleration required for its circular trajectory. When this happens, the distance between the cube and the axis of rotation increases until the cube slides off the edge. ✔

4 EVALUATE RESULT What makes the cube slide off the turntable is its tendency to continue in a straight line (that is, on a trajectory tangent to its circular trajectory). Up to a certain speed the force of static friction is large enough to overcome this tendency and keep the cube moving in a circle. Once the force of static friction reaches its maximum value, the cube begins to slide.



CONCEPTS

It is all too easy to think that there must be an *outward* force pushing the cube off the turntable as the rotational velocity increases in Example 11.3. As in a car rounding a corner, this thought arises because, without realizing it, you tend to view the situation from the rotating frame of the turntable. Because this is an easy mistake to make in situations involving rotation, you must always make sure you choose an inertial frame of reference.

If you can't imagine the cube moving off the turntable without being *pushed* off, try the following: Put some object—an eraser or your keys will do—on top and near the edge of a book as in **Figure 11.16*a*** and then gently, without touching the object, push the book along the surface of a table. The object moves along because it is being pushed forward by the force of static friction exerted by the book on it. If you give the book a hard shove, however, the object lags behind and falls off the rear edge of the book. Did it get pushed off—by, say, air resistance? Someone moving along with the book might claim it did—just as someone in an accelerating car feels "pushed backward"—but such a person is not in an inertial reference frame. (Also, this experiment would work even in a vacuum.) From the point of view of someone in the Earth reference frame, the book got yanked from under the object. The force of static friction exerted by the book on the object is not large enough to give the object the same acceleration as the book, and so the object falls off the rear edge without anything physically pushing it off. If you mark its starting position, you will notice that the object always ends up in front of its starting position, as shown in Figure 11.16*b*. This observation tells you that, even though it falls off the rear edge of the book, the object must have been pushed in the *forward* direction. It falls off the book not because it has been pushed off, but because the forward push exerted by the book on the object is not large enough for the object to keep up with the accelerating book.

The same is true for the cube on the turntable: It falls off the edge not because it is pushed off but because the force of static friction between turntable and cube is not large enough to force the cube to go around in a circle.

Figure 11.16 The eraser in (*b*) falls off the book because of inertia, not because of a force "pushing" it off the book.

11.2 Suppose I have two cubes on a turntable at equal distances from the axis of rotation. The inertia of cube 1 is twice that of cube 2. Do both cubes begin sliding at the same instant if I slowly increase the rotational velocity?

Figure 11.17 shows free-body diagrams for three objects moving in circular motion at constant speed. In each case the vector sum of the forces exerted on the object points toward the center of the circular trajectory.

11.3 (*a*) Does a bicycle always have to lean into a curve as illustrated in Figure 11.17*a*? (*b*) The rope holding the bucket in Figure 11.17*b* makes a small angle with the horizontal. Is it possible to swing the bucket around so that the rope is exactly horizontal?

11.3 Rotational inertia

Having established the principles of circular motion at constant speed, let us now examine *changes* in rotational velocity. Imagine two identical pucks A and B on a horizontal air table (**Figure 11.18**). Puck B is initially at rest and fastened to a vertical post in the middle of the table by a short string that constrains the puck's motion to a circle of radius r_B. Suppose we give puck A a shove so that it strikes stationary puck B at speed v, as illustrated in Figure 11.18*a*. The two pucks collide elastically, and so immediately after the collision puck A is at rest and puck B has speed v. Puck B then begins to move around the post in circular motion at constant speed v. If the change in its rotational coordinate during a time interval Δt is $\Delta\vartheta_B$, then its rotational velocity after the collision is $\omega_{B\vartheta} = \Delta\vartheta_B/\Delta t$.

Now suppose we shove puck A at the same initial speed v toward a third identical puck C initially at rest and attached to a string of length $r_C > r_B$, as in

CONCEPTS

Figure 11.17 Free-body diagrams for three objects in circular motion at constant speed.

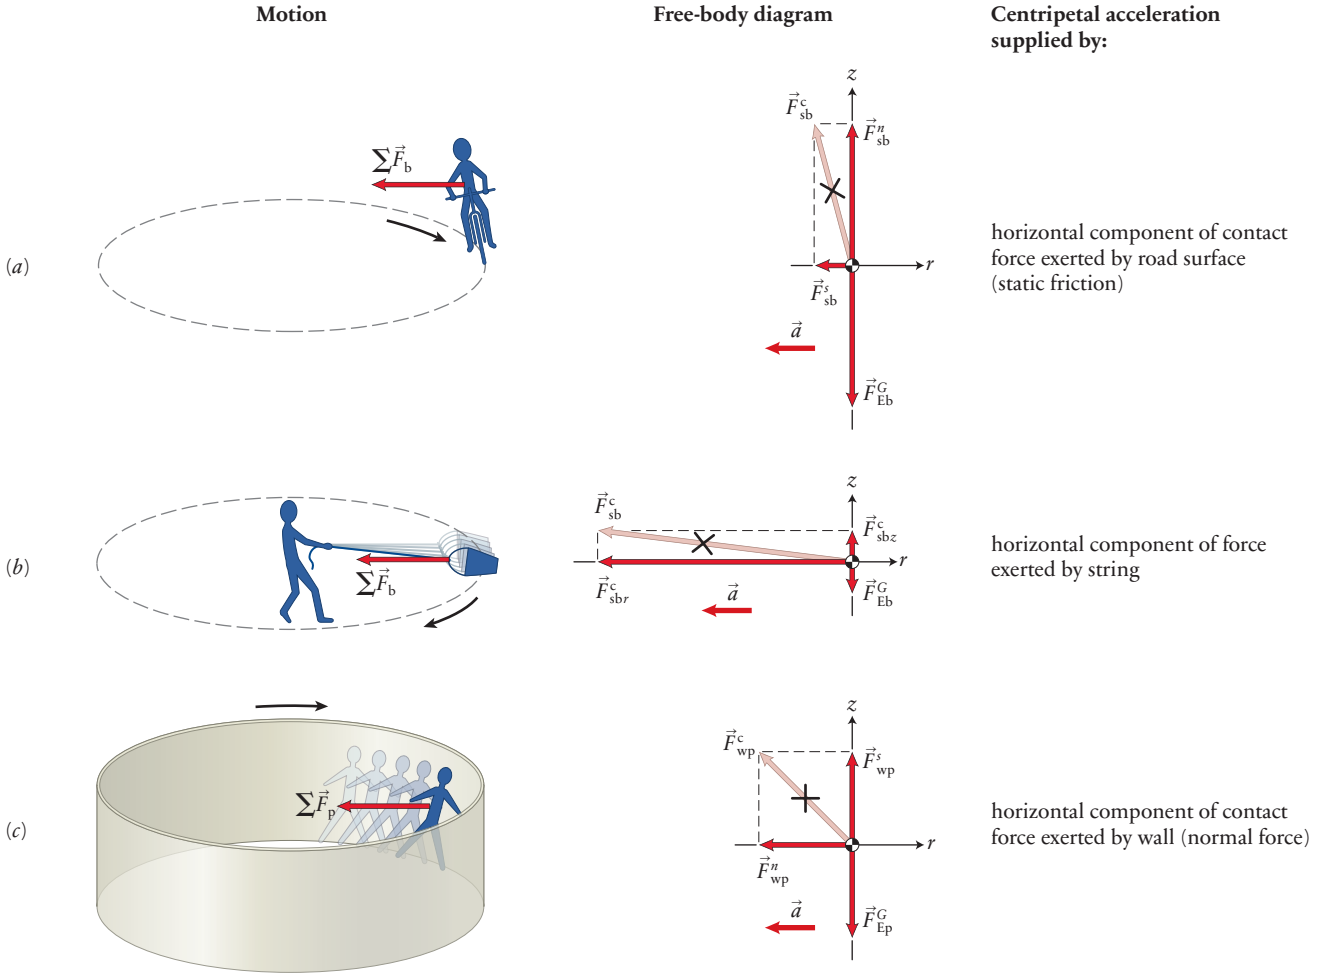


Figure 11.18 When a moving puck strikes a stationary puck attached to a string, the rotational velocity of the puck on the string depends on string length.

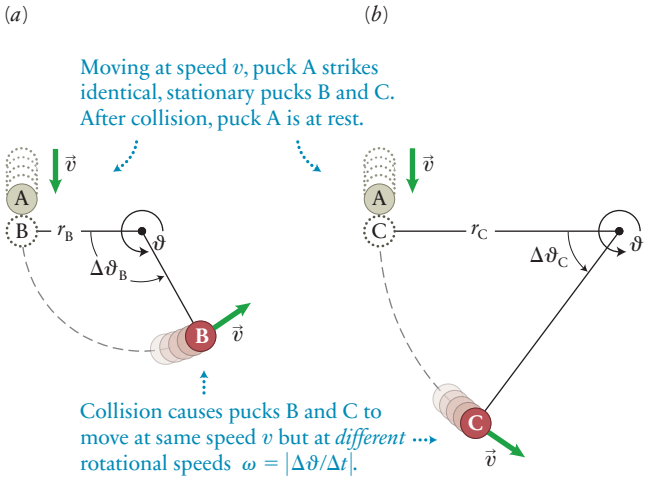

Figure 11.18*b*. As before, puck A comes to rest after the collision and puck C moves away with speed v. Because both pucks B and C have the same speed v after the collision, they travel the same arc length in the same time interval Δt. However, their *rotational* speeds are different because the radii of their trajectories are different. The magnitude of the change $\Delta\vartheta_C$ in the rotational coordinate of C during the time interval Δt is smaller than that of B, and C's rotational speed, $\omega_C = |\Delta\vartheta_C/\Delta t|$, is therefore smaller than that of B.

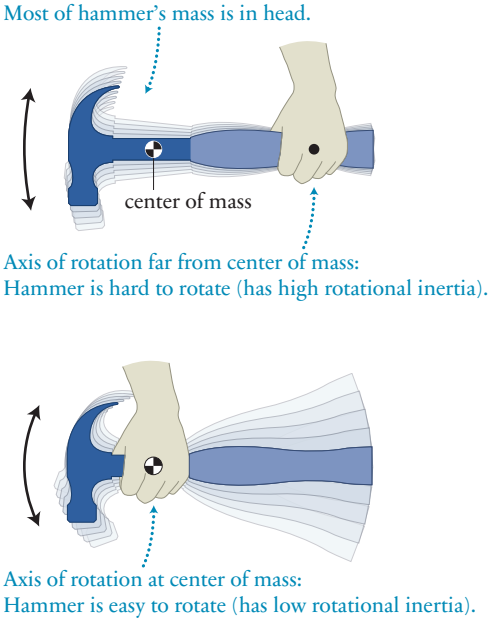
If puck C is to attain the same final rotational velocity as B, it needs to be struck by a considerably faster moving puck A. Put differently, it is more difficult to change the rotational velocity of C than it is to change that of B. Note that C and B have the same inertia. If it weren't for the presence of the strings of different lengths, we would not be able to distinguish them: Once hit by A, both C and B would move off in a

CONCEPTS



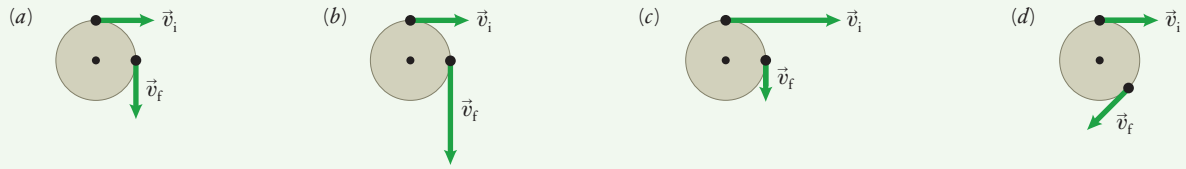
straight line with the same speed v. Apparently an object's tendency to resist a change in rotational velocity, its **rotational inertia,** is not given by simply the object's inertia—the object's tendency to resist a change in velocity as we defined it in Chapter 4. (The inertia surely plays a role: If I increase the inertia of puck B, its rotational speed after the collision is lower and so is its change in rotational velocity.) That the longer string on C causes C's rotational velocity to change less than B's suggests that an object's rotational inertia depends on its location relative to the axis of rotation. The greater the distance between the bulk of an object's material and the axis of rotation, the larger its rotational inertia. You can easily verify this using a hammer (**Figure 11.19**). If you hold the hammer near its head, it is easily rotated. If you hold the hammer at the handle, as you would normally, it is more difficult to rotate.

There are many examples of the effect of rotational inertia. Skaters reduce their rotational inertia, and therefore spin more easily, by holding their arms close to their bodies; you run faster with your legs bent than with them extended. Conversely, when trying to keep your balance on a beam, you spread out your arms. This action moves more of your inertia away from the rotation axis and so increases your rotational inertia, which in turn increases your resistance to rotating off the beam. Tightrope walkers use a long pole for the same reason: The pole puts more inertia farther from the rotation axis and so increases the walkers' rotational inertia and gives them more time to adjust their balance.

One final important point: Unlike inertia, which has a single value, rotational inertia depends on the location of the rotation axis. An object can have a small rotational inertia about one axis and a large rotational inertia about another axis—just think of the hammer in Figure 11.19. Therefore the value of rotational inertia cannot be determined unless you specify the axis of rotation.

11.4 About which axis is the rotational inertia of a pencil (*a*) largest and (*b*) smallest: (1) a lengthwise axis through the core of the pencil; (2) an axis perpendicular to the pencil's length and passing through its midpoint; (3) an axis perpendicular to the pencil's length and passing through its tip?

Figure 11.19 The rotational inertia of a hammer—its resistance to rotational motion—depends on the location of the axis of rotation.

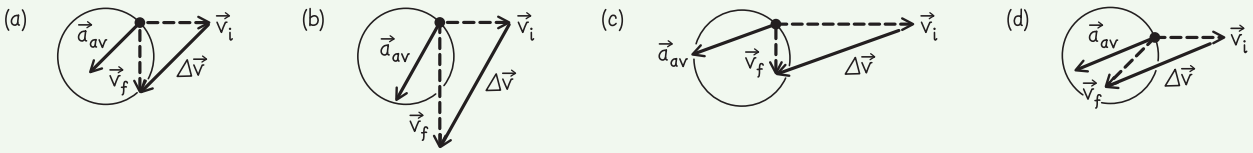


CONCEPTS

Self-quiz

1. Which of the following is in translational equilibrium? (*a*) An object whose center of mass is undergoing circular motion at constant speed. (*b*) A wheel spinning about an axis through its center of mass.
2. **Figure 11.20** shows the velocities $\vec{v}_i$ and $\vec{v}_f$ of a point on the rim of an object at two instants t_i and t_f for four different motions. For each case, determine the change in velocity $\Delta\vec{v}$ and the direction of the average acceleration at a point in time halfway between t_i and t_f.

Figure 11.20



3. Why doesn't the acceleration in question 2 point toward the center of the circle in all cases?
4. Describe the interaction responsible for providing a centripetal acceleration for (*a*) a car rounding a level curve, (*b*) a car rounding a banked curve, (*c*) a coin rotating on a turntable, (*d*) a ball swung through a horizontal circle by a string that sweeps out a cone, (*e*) the Moon orbiting Earth, (*f*) clothes spinning in a dryer, (*g*) a marble rolling along the inside of a horizontal hoop, and (*h*) a ball on a string rolling in a horizontal circle on a surface.
5. A ball attached to a string (the far end of which is fixed) rolls in a horizontal circle. Under which conditions is the string more likely to break: (*a*) when the speed of the ball is increased for a given radius or (*b*) when the length of the string is increased for a given speed?

Answers

1. (*a*) An object undergoing circular motion at constant speed is accelerated because the direction of its center-of-mass velocity changes continuously. If it is accelerated, the vector sum of the forces exerted on the object is not zero, and the object cannot be in translational equilibrium. (*b*) If the center of mass of a spinning wheel is fixed, $a_{cm} = 0$ and so the object is in translational equilibrium.
2. For each case, $\Delta\vec{v} = \vec{v}_f - \vec{v}_i$ and the average acceleration is parallel to $\Delta\vec{v}$ (**Figure 11.21**).

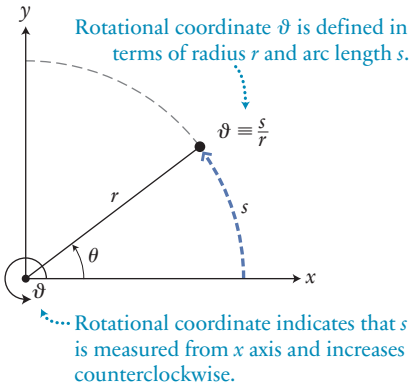


Figure 11.21

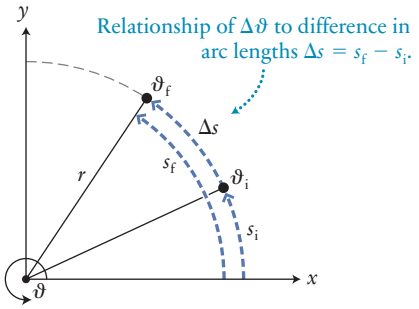


3. Notice that as the object travels around the circle in parts *b* and *c*, its speed changes. To change the speed, there must be a tangential component to the acceleration as well as a centripetal component. The tangential component requires that the acceleration not point directly toward the center.
4. (*a*) Force of static friction exerted by road on car, (*b*) horizontal component of contact force exerted by road on car, (*c*) force of static friction exerted by turntable on coin, (*d*) horizontal component of tensile force exerted by string on ball, (*e*) gravitational force exerted by Earth on the Moon, (*f*) centripetal component of contact force exerted by drum of dryer on clothes, (*g*) contact force exerted by hoop on marble, and (*h*) tensile force exerted by string on ball.
5. In case *a*, for a given radius, a greater speed means the ball travels through a larger angle during a specific time interval. If the angle is larger, the magnitude of $\Delta\vec{v}$ is larger. A larger magnitude of $\Delta\vec{v}$ requires that the acceleration and force also be larger. The force providing the acceleration is due to the tension in the string. Therefore, the greater speed requires more tension and the string is more likely to break. In case *b*, for a given speed, a larger radius means that the ball travels through a smaller angle in a specific time interval. If the angle is smaller, the magnitude of $\Delta\vec{v}$ is smaller. A smaller $\Delta\vec{v}$ requires a smaller acceleration and a smaller force. Therefore, a large radius requires a smaller tension in the string and the string is less likely to break.

Figure 11.22 Relationships between rotational coordinate ϑ, radius r, and arc length s.

(*a*)

(*b*)

11.4 Rotational kinematics

The **rotational coordinate** of an object moving along a circle of radius r is defined as the length of the arc s over which the object has moved divided by the radius:

$$\vartheta \equiv \frac{s}{r}. \tag{11.1}$$

The sign and magnitude of s (and therefore the sign and magnitude of ϑ) depend on our choice of rotational coordinate system. With the choice of rotational coordinate system shown in **Figure 11.22*a***, s is measured along the perimeter of the circle, beginning at the positive x axis and ending at the location of the object, and the counterclockwise direction is taken to be positive. Because the rotational coordinate ϑ is a ratio of two lengths, it is a unitless quantity. In contrast, the polar angle θ swept out by the revolving object can be expressed in *radians* (rad), *degrees* (°), or *revolutions* (rev). The relationship between these units is

$$2\pi \text{ rad} = 360° = 1 \text{ rev}. \tag{11.2}$$

Note that, unlike the units for length, time, and inertia, no physical standard is required to specify the units for polar angle.

Rotational coordinate and polar angle are directly related to each other. After one revolution, the arc length s traveled by the object is equal to the circumference of the circle, and so $s = 2\pi r$. Substituting this value for s in Eq. 11.1 yields $\vartheta = 2\pi$ after one revolution. Knowing from Eq. 11.2 that 2π rad $= 1$ rev, we see that the rotational coordinate corresponds to the *number of radians in the polar angle*: $\vartheta = \theta/(1 \text{ rad})$.* In other words, given the polar angle θ of the object's position, we can obtain its rotational coordinate by expressing the polar angle in radians and dividing by 1 rad.

The change in the rotational coordinate of an object, the object's final rotational coordinate minus its initial rotational coordinate, is

$$\Delta\vartheta \equiv \vartheta_f - \vartheta_i. \tag{11.3}$$

This quantity is positive for a rotation in the direction of increasing ϑ and negative for a rotation in the direction of decreasing ϑ. Combining this expression with Eq. 11.1 allows us to express $\Delta\vartheta$ as a difference in arc lengths:

$$\Delta\vartheta = \vartheta_f - \vartheta_i = \frac{s_f}{r} - \frac{s_i}{r} = \frac{\Delta s}{r}, \tag{11.4}$$

where Δs is defined as the length of the arc between the final and initial locations of the object, as shown in Figure 11.22*b*.

11.5 Starting from a position with rotational coordinate zero, an object moves in the positive ϑ direction at a constant speed of 3.0 m/s along the perimeter of a circle of radius 2.0 m. (*a*) What is the object's rotational coordinate after 1.5 s? (*b*) How long does it take the object to complete one revolution? (*c*) What is its rotational coordinate 1.0 s after passing a point on the circle whose polar angle is 90°?

QUANTITATIVE TOOLS

* The reason for this division by 1 rad is to cancel out the units of radian. The rotational coordinate ϑ is unitless, but the polar angle θ has units of radians. So for an object that has rotated to an angle of 6.1 rad, the rotational coordinate is $(6.1 \text{ rad})/(1 \text{ rad}) = 6.1$; for an object that has rotated to an angle of 265°, the rotational coordinate is $(265°)(2\pi \text{ rad}/360°)/(1 \text{ rad}) = 4.63$.

In analogy to the definition of average velocity, we can define *average rotational velocity* $\omega_{\vartheta,\text{av}}$ as being equal to the change in the rotational coordinate divided by the time interval during which this change takes place:

$$\omega_{\vartheta,\text{av}} \equiv \frac{\Delta\vartheta}{\Delta t}. \tag{11.5}$$

The SI unit of average rotational velocity is s^{-1} (inverse second). The subscript ϑ is there to remind us that the average rotational velocity is a signed quantity that can be positive or negative, depending on the choice of positive direction of rotation for ϑ.

The **rotational velocity** ω_ϑ is obtained by letting the time interval during which the change in the rotational coordinate is measured approach zero:

$$\omega_\vartheta \equiv \lim_{\Delta t\to 0} \frac{\Delta\vartheta}{\Delta t} = \frac{d\vartheta}{dt}. \tag{11.6}$$

The instantaneous rotational velocity is equal to the time derivative of the rotational coordinate just as the instantaneous velocity is equal to the time derivative of position. The **rotational speed** is the absolute value of the rotational velocity:

$$\omega = |\omega_\vartheta|. \tag{11.7}$$

The relationship between instantaneous rotational velocity and instantaneous velocity can be obtained by substituting Eq. 11.4 into Eq. 11.5:

$$\omega_\vartheta = \frac{d\vartheta}{dt} = \frac{1}{r}\frac{ds}{dt}. \tag{11.8}$$

Because the rate at which the arc length s is swept out is the tangential component of the velocity of the object, $v_t = ds/dt$, we have

$$\omega_\vartheta = \frac{v_t}{r} \tag{11.9}$$

or

$$v_t = r\omega_\vartheta. \tag{11.10}$$

Both the tangential component of the velocity v_t and the rotational velocity ω_ϑ are signed quantities that are positive for motion in the direction of increasing ϑ and negative in the direction of decreasing ϑ. We can also express Eq. 11.10 in terms of speeds:

$$v = r\omega. \tag{11.11}$$

In words, the speed of an object in circular motion equals its rotational speed multiplied by the radius of the circular path. As we concluded when we analyzed Figure 11.6, the speed increases with increasing radius.

We can also define a **rotational acceleration** α_ϑ (Greek letter alpha):

$$\alpha_\vartheta \equiv \lim_{\Delta t\to 0} \frac{\Delta\omega_\vartheta}{\Delta t} = \frac{d\omega_\vartheta}{dt} = \frac{d^2\vartheta}{dt^2}. \tag{11.12}$$

The rotational acceleration has SI units s^{-2} (inverse seconds squared). It is a measure of the rate at which the rotational velocity increases.

For *circular motion at constant speed,* the rotational speed $\omega = v/r$ is constant, and so the rotational acceleration is zero. How can rotational acceleration be zero if, as we saw in Section 11.1, circular motion at constant

speed requires a nonzero centripetal acceleration? The answer is that rotational acceleration measures the change in the magnitude of the velocity $\vec{v}$ with which an object travels around a circle, while centripetal acceleration measures the change in the *direction* of $\vec{v}$. Even if the object's speed v is constant, meaning its rotational acceleration is zero, the changing direction of $\vec{v}$ means there is a nonzero centripetal acceleration.

To obtain the magnitude of the centripetal acceleration, remember that if the position vector of a revolving object sweeps out an angle θ, the velocity vector $\vec{v}$ sweeps out the same angle, as illustrated in **Figure 11.23**. This means that the two shaded triangles in Figure 11.23 are similar and so

$$\frac{|\Delta\vec{r}\,|}{r} = \frac{|\Delta\vec{v}\,|}{v} \tag{11.13}$$

or, rearranging terms and dividing left and right by the time interval Δt during which the change in velocity direction took place,

$$\frac{|\Delta\vec{v}\,|}{\Delta t} = \frac{v}{r}\frac{|\Delta\vec{r}\,|}{\Delta t}. \tag{11.14}$$

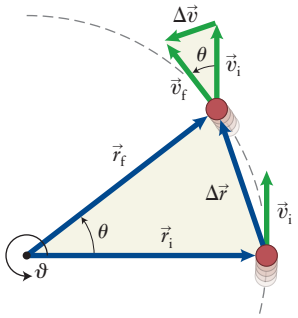
In the limit for $\Delta t \to 0$, the term $|\Delta\vec{v}\,|/\Delta t$ approaches the magnitude of the (centripetal) acceleration, which we shall denote by a_c, and the term $|\Delta\vec{r}\,|/\Delta t$ approaches the speed v, and so the magnitude of the **centripetal acceleration** is

$$a_c = \frac{v^2}{r} \quad \text{(circular motion)}. \tag{11.15}$$

This is the acceleration required to keep an object moving at speed v along the perimeter of a circle of radius r. As we saw in Section 11.1, the centripetal acceleration of an object executing a circular motion at constant speed is directed radially inward.

Although we derived Eq. 11.15 for circular motion at constant speed, *any* object constrained to move along a circle or part of a circle of radius r is subject to a radially inward acceleration of the magnitude given by Eq. 11.15. Because we defined the radial axis to be directed outward from the rotation axis (Figure 11.11), we can write

$$a_r = -\frac{v^2}{r} \quad \text{(any motion along arc of radius } r\text{)}. \tag{11.16}$$



When the object's speed is not constant, we have, in addition to this radial component of the acceleration, a component parallel to the velocity (see Checkpoint 11.1). This component is called the **tangential acceleration** because it is always tangent to the trajectory:

$$a_t = \frac{dv}{dt}. \tag{11.17}$$

The tangential component is positive when the speed increases and negative when it decreases.

Figure 11.24 summarizes a number of important facts about circular motion. Figure 11.24*a* illustrates circular motion at constant speed and Figure 11.24*b* accelerated circular motion. Note that the velocity is always tangential to the trajectory: that is, the radial component of the velocity is

Figure 11.23 Change in the direction of the position $\vec{r}$ and the velocity $\vec{v}$ for an object moving in a circle at constant speed.

QUANTITATIVE TOOLS

always zero. This is true for any type of circular motion, be it at constant speed or accelerated:

$$v_r = 0 \quad \text{(any type of circular motion)}. \tag{11.18}$$

When the circular motion is at constant speed, the radial component of the acceleration is nonzero (Eq. 11.16) and the tangential acceleration is zero:

$$a_t = 0 \quad \text{(circular motion at constant speed)}. \tag{11.19}$$

In that case, the **period** T (the time interval it takes the object to complete one revolution) is

$$T = \frac{2\pi r}{v} = \frac{2\pi}{\omega} \quad \text{(circular motion at constant speed)}, \tag{11.20}$$

where we have used Eq. 11.11 relating the speed v to the rotational speed ω.

If the object speeds up or slows down, both components of the acceleration are nonzero. The acceleration no longer points to the center of the circle, as shown in Figure 11.24*c*, and the magnitude of the acceleration is

$$a = \sqrt{a_r^2 + a_t^2}. \tag{11.21}$$

When the tangential acceleration is nonzero, the rotational acceleration is nonzero too. To relate these two quantities, we substitute Eq. 11.10 for v_t:

$$a_t = \frac{dv_t}{dt} = r\frac{d\omega_\vartheta}{dt}. \tag{11.22}$$

Noting that $d\omega_\vartheta/dt$ is the rotational acceleration α_ϑ (Eq. 11.12), we can write Eq. 11.22 in the form

$$a_t = r\alpha_\vartheta. \tag{11.23}$$

Thus tangential acceleration is related to rotational acceleration in the same way that velocity and rotational velocity are related (Eq. 11.10) and, similarly, arc length and rotational coordinate (Eq. 11.1). For all three we can write (**Table 11.1**):

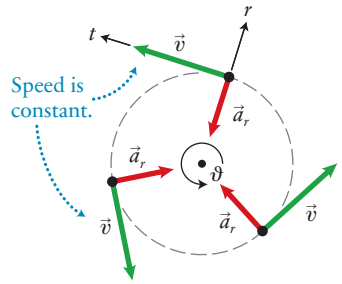
translational motion quantity $= r \times$ rotational motion quantity.

If a_t is constant (and so the rotational acceleration is constant too), then the arc length traveled and the tangential velocity are given by the kinematics equations for motion at constant acceleration (Eqs. 3.8 and 3.4):

$$s_\text{f} = s_\text{i} + v_{t,\text{i}}\Delta t + \tfrac{1}{2}a_t(\Delta t)^2 \tag{11.24}$$

$$v_{t,\text{f}} = v_{t,\text{i}} + a_t\Delta t. \tag{11.25}$$

Dividing both sides of each of these equations by r and substituting the expressions from Table 11.1, we obtain the equivalent kinematics equations for rotational motion:



$$\vartheta_\text{f} = \vartheta_\text{i} + \omega_{\vartheta,\text{i}}\Delta t + \tfrac{1}{2}\alpha_\vartheta(\Delta t)^2 \quad \text{(constant rotational acceleration)} \tag{11.26}$$

$$\omega_{\vartheta,\text{f}} = \omega_{\vartheta,i} + \alpha_\vartheta\Delta t \quad \text{(constant rotational acceleration)}. \tag{11.27}$$

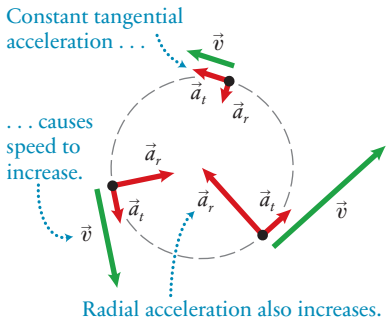


Table 11.2 gives an overview of the correspondence between translational and rotational kinematic quantities and equations.

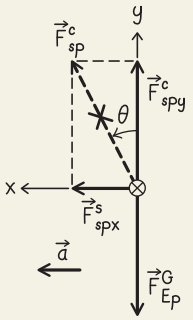
EXAMPLE 11.4 Leaning into a curve



A woman is rollerblading to work and, running late, rounds a corner at full speed, sharply leaning into the curve (**Figure 11.25**). If, during the turn, she goes along the arc of a circle of radius 4.5 m at a constant speed of 5.0 m/s, what angle θ must her body make with the vertical in order to round the curve without falling?

Figure 11.25 Example 11.4.

❶ **GETTING STARTED** As she rounds the circular arc at constant speed, the woman executes circular motion at constant speed. She must therefore undergo a centripetal acceleration as a result of the forces exerted on her. To help me determine the forces exerted on her, I draw a free-body diagram (**Figure 11.26**). The forces exerted on the rollerblader are the gravitational force $\vec{F}^G_{Ep}$ and a contact force $\vec{F}^c_{sp}$ exerted by the surface of the road. Now I see why she must lean into the turn: When she stands straight, the contact force is

Figure 11.26

directed straight up, but as she leans, this force develops a component that pushes her toward the center of the circular arc and provides the necessary centripetal acceleration. I indicate the direction of this centripetal acceleration in my drawing and choose a set of axes—the x axis in the direction of the centripetal acceleration and the y axis upward. (Note that the resulting free-body diagram is similar to that for the bicyclist in Figure 11.17*a*.) I must determine the angle θ that $\vec{F}^c_{sp}$ makes with the vertical.

❷ **DEVISE PLAN** From my free-body diagram, I can draw two conclusions. First, the forces in the y direction must add to zero: $\Sigma F_y = 0$. Second, the x component of the contact force provides the centripetal acceleration given by Eq. 11.15. This gives me two equations from which I should be able to determine θ.

❸ **EXECUTE PLAN** Substituting the centripetal acceleration from Eq. 11.15 into the equation of motion in the x direction, I get

$$\Sigma F_x = ma_x = m(+a_c) = +m\frac{v^2}{r}, \qquad (1)$$

where m is the inertia of the rollerblader. (The rollerblader's inertia is not given, but I hope it will drop out and I won't need it.) From my diagram, I see that

$$\Sigma F_x = F^c_{spx} = F^c_{sp}\sin\theta. \qquad (2)$$

QUANTITATIVE TOOLS

In the y direction I have $F^c_{spy} = F^c_{sp}\cos\theta$ and $F^G_{Epy} = -mg$. The equation of motion in the y direction then yields

$$\Sigma F_y = F^c_{spy} + F^G_{Epy} = F^c_{sp}\cos\theta - mg = 0.$$

Solving this equation for F^c_{sp} and substituting the result into Eq. 2, I get

$$\Sigma F_x = F^c_{sp}\sin\theta = \left(\frac{mg}{\cos\theta}\right)\sin\theta = mg\tan\theta.$$

Substituting this result into Eq. 1 then yields

$$mg\tan\theta = m\frac{v^2}{r}$$

$$\tan\theta = \frac{v^2}{gr} = \frac{(5.0\text{ m/s})^2}{(9.8\text{ m/s}^2)(4.5\text{ m})} = 0.57.$$

This gives an angle $\theta = \tan^{-1}(0.57) = 0.52$ rad, or about 30°. ✔

❹ **EVALUATE RESULT** The rollerblader's angle in Figure 11.25 is about 30°, and so my answer appears to be reasonable.

11.6 Estimate the maximum speed with which you could take the curve in Example 11.4. [Hint: What is the coefficient of static friction?]

11.5 Angular momentum

Let us now return to the experiment discussed in Section 11.3: A stationary puck C fastened to a string of length r is struck by an identical puck A initially moving at speed v. For simplicity we'll ignore the pucks' extent and treat them as particles. After the elastic collision, the puck C moves in circular motion at constant speed v. Calling this puck's inertia m, we can say that its kinetic energy is

$$K = \tfrac{1}{2}mv^2. \tag{11.28}$$

Substituting the expression given by Eq. 11.10 for v, we can rewrite this kinetic energy in the form

$$K = \tfrac{1}{2}mv^2 = \tfrac{1}{2}m(r\omega)^2 = \tfrac{1}{2}(mr^2)\omega^2 \tag{11.29}$$

or, defining the term in parentheses as the **rotational inertia** I of puck C about the axis of rotation

$$I \equiv mr^2 \quad \text{(particle)}, \tag{11.30}$$

we get

$$K_{rot} = \tfrac{1}{2}I\omega^2. \tag{11.31}$$

The rotational inertia of an object about an axis opposes a change in rotational motion about that axis just as inertia opposes a change in translational motion. The SI unit of rotational inertia is $\text{kg}\cdot\text{m}^2$. Because the SI unit of ω is s^{-1}, we get, from Eq. 11.31 SI units of $\text{kg}\cdot\text{m}^2/\text{s}^2$ for the kinetic energy, which is the joule.

Note the remarkable similarity between Eqs. 11.31 and 11.28—inertia m and speed v of Eq. 11.28 are replaced by their rotational equivalents, rotational inertia I and rotational speed ω. The main advantage of writing the kinetic energy in the form of Eq. 11.31 will become clear when we deal with rotating extended objects in Section 11.6: The rotational velocity is the same in all parts of a rotating object, whereas the speed depends on the distance to the axis of rotation (recall Figure 11.7). Because the kinetic energy in Eq. 11.31 is due to rotational motion, it is called the **rotational kinetic energy** of the object.

11.7 Suppose that in Figure 11.18 $r_C = 2r_B$. (*a*) What is the ratio of the rotational velocity of B to that of C? (*b*) What is the ratio of the rotational inertia of B to that of C?

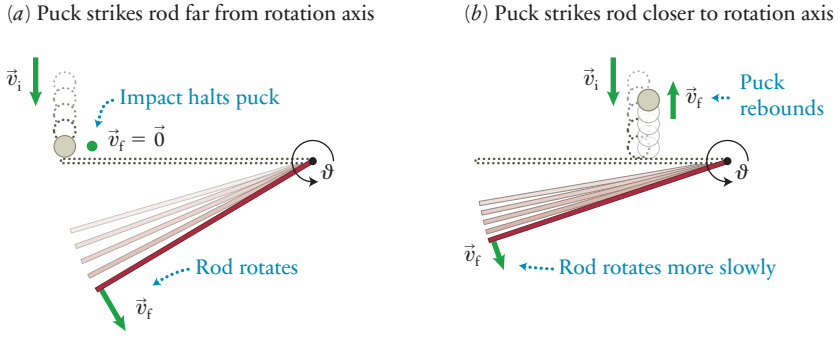
The answers to this checkpoint might surprise you. That the rotational inertia of B is only one-fourth that of C means that B has only one-*fourth* the tendency to resist a change in its rotational motion. So why, when the same force is exerted, is B's rotational velocity only *twice* as large as C's rather than four times as much?

The reason the rotational velocity of B is not as great as you might expect is that the rotational velocity an object acquires depends on how far from the rotation axis it is struck. Increasing the string's length in Figure 11.18 not only increases the puck's rotational inertia but also increases the effectiveness of the blow from the incoming puck. Doubling r for puck C quadruples C's rotational inertia because of the factor r^2 in Eq. 11.30 but also increases puck A's ability to set C in rotational motion. As a result, B's rotational velocity is only twice that of C rather than four times as much.

Figure 11.27 shows two collisions between a bar that is free to rotate about its right end and a puck. In Figure 11.27*a* the puck strikes the end of the rod; in Figure 11.27*b* the rod is struck closer to the axis. Although the rotational inertia of the rod is fixed and although the puck has the same initial momentum, the rod rotates more slowly when struck closer to the rotation axis. (In the extreme case that it is hit right on the axis, the rod doesn't move at all.) So the incoming puck's ability to set other objects in rotational motion depends not only on its momentum but also on how far from the axis it strikes the other object.

Returning to the collision of Section 11.3, we have seen that substituting ω for v and I for m in the expression $\frac{1}{2}mv^2$ yields the final kinetic energy of the struck puck (C in our case), which is equal to the initial kinetic energy of the incoming puck (A):

$$\tfrac{1}{2}mv^2 \rightarrow \tfrac{1}{2}I\omega^2 = \tfrac{1}{2}(mr^2)\left(\frac{v}{r}\right)^2 = \tfrac{1}{2}mv^2. \qquad (11.32)$$



This relationship tells us that the elastic collision causes all the (translational) kinetic energy initially in puck A to be converted to the rotational kinetic energy of puck C. The sum of the kinetic energy of puck A and the rotational kinetic energy of puck C (that is to say, the kinetic energy of the two-puck system) remains constant, as it should.

What happens if we make the same $m \rightarrow I$, $v \rightarrow \omega$ substitutions in mv, the magnitude of the momentum of puck A? Let's try it:

$$mv \rightarrow I\omega = (mr^2)\left(\frac{v}{r}\right) = rmv. \qquad (11.33)$$

The result is different this time: The quantity $I\omega$ is not equal to the magnitude mv of the momentum of the incoming puck A. Instead $I\omega$ is equal to the product of mv and the distance r from A to the axis of rotation at the instant of impact. This "rotational momentum" $I\omega$ thus represents precisely

Figure 11.27 A rod free to rotate about one end is struck by an incoming puck at different distances from its axis of rotation.

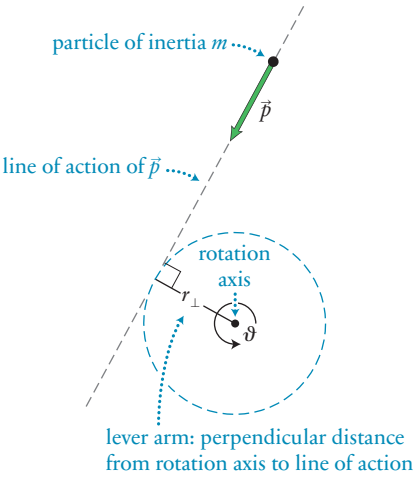
QUANTITATIVE TOOLS

what we called the "ability to set in rotational motion" a moment ago: The greater the distance r between the location of impact and the axis of rotation, the larger rmv and the easier it is for puck A to make puck C rotate.

The quantity $I\omega$ plays a fundamental role in physics. The larger the value of $I\omega$ for a moving object, the more easily the object can set another object in rotational motion. Because of the analogy to momentum, which measures an object's capacity to set other objects in motion along a straight line, this quantity is called the **angular momentum** and is denoted by the letter L:

$$L_\vartheta \equiv I\omega_\vartheta. \tag{11.34}$$

The SI units of angular momentum are kg · m^2/s. As before, the subscript ϑ means that the angular momentum, like the rotational velocity, is a signed quantity that can be positive or negative, depending on the choice of the positive direction of rotation for ϑ. Substituting Eqs. 11.10 and 11.30 into Eq. 11.34, we get



$$L_\vartheta \equiv I\omega_\vartheta = (mr^2)\left(\frac{v_t}{r}\right) = rmv_t. \tag{11.35}$$

An object does not need to rotate or revolve in order to possess a nonzero angular momentum. For example, even though it moves in a straight line, the incoming puck A in Figure 11.18 has a nonzero angular momentum—it has the ability to set another puck in rotational motion. You can use Eqs. 11.34 and 11.35 to calculate the angular momentum of objects in circular motion, but what is the angular momentum of an object that moves along a straight line? The first thing to note is that it doesn't make sense to talk about the angular momentum of an object unless we specify an axis of rotation. **Figure 11.28** shows how to determine the angular momentum for a particle moving along a straight line. For a given axis of rotation (real or imagined), the value of r in Eq. 11.35 is given by the perpendicular distance $r_\perp$ between the axis of rotation and the straight line defined by the momentum of the object (the radius of the circle for which this line, called the *line of action* of the momentum, is a tangent; see Figure 11.28), while the value of v_t is the speed of the object. The distance $r_\perp$ is called the **lever arm distance,** or simply **lever arm,** of the momentum relative to the axis of rotation. The magnitude of the angular momentum of a particle that moves along a straight line is thus

$$L = r_\perp mv \quad \text{(particle)}. \tag{11.36}$$

The sign of the angular momentum is determined by the choice of the positive direction of rotation for ϑ. For example, the rotational coordinate of the particle in Figure 11.28 is increasing as it moves along its straight trajectory, and so the angular momentum of the particle is positive.

Figure 11.28 Relative to an axis of rotation, a particle of inertia m moving along a straight line has an angular momentum of magnitude $r_\perp mv$, where $r_\perp$ is the lever arm distance and v is the speed of the object.

EXERCISE 11.5 Angular momenta

Determine the angular momenta of objects A and B in **Figure 11.29** relative to (*a*) axis 1 and (*b*) axis 2. The inertia of the objects are $m_A = 2.0$ kg and $m_B = 0.50$ kg, and their speeds are $v_A = 0.60$ m/s and $v_B = 1.0$ m/s. The tall side of the rectangle is 2.0 m long and object B travels along the diagonal, which makes an angle of 30° with the long side of the rectangle.

SOLUTION (*a*) Object A: The lever arm distance relative to axis 1 is the long side of the rectangle: $r_\perp = 2.0$ m. The angular momentum is therefore

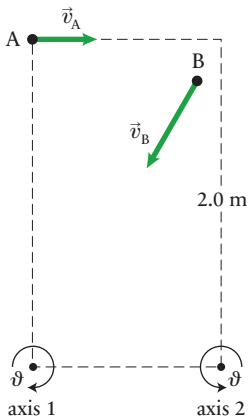
$$L_{A\vartheta} = +(2.0\text{ m})(2.0\text{ kg})(0.60\text{ m/s}) = +2.4\text{ kg}\cdot\text{m}^2/\text{s}.$$

The plus sign indicates that the rotational coordinate of A relative to axis 1 increases. ✔

Object B: B's line of motion is the diagonal of the rectangle and so goes through axis 1. Therefore $r_\perp = 0$ and thus $L_{B\vartheta} = 0$. ✔

(Continued)

Figure 11.29 Exercise 11.5.



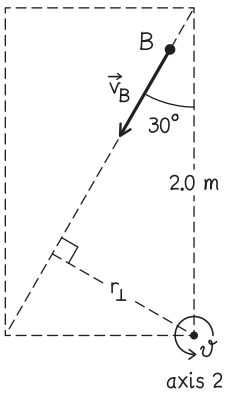


Figure 11.30

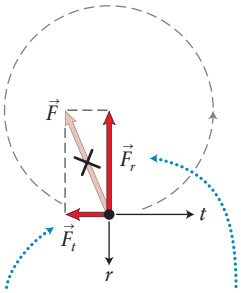
(*b*) Object A: The lever arm distance relative to axis 2 is the long side of the rectangle: $r_\perp = 2.0$ m. The angular momentum is therefore $L_{A\vartheta} = -(2.0\text{ m})(2.0\text{ kg})(0.60\text{ m/s}) = -2.4\text{ kg}\cdot\text{m}^2/\text{s}$. The minus sign indicates that the rotational coordinate of A relative to axis 2 decreases. ✔



Object B: To determine $r_\perp$ relative to axis 2, I draw a straight line perpendicular to B's line of motion (**Figure 11.30**). Using trigonometry, I see that $\sin 30° = r_\perp/(2.0\text{ m})$, or $r_\perp = (0.5)(2.0\text{ m}) = 1.0$ m, and so $L_{B\vartheta} = +(1.0\text{ m})\ (0.50\text{ kg})(1.0\text{ m/s}) = +0.50\text{ kg}\cdot\text{m}^2/\text{s}$. The plus sign indicates that the rotational coordinate of B relative to axis 2 increases. ✔

Going back to the experiment we discussed in Section 11.3, if we substitute the values of m, $r_\perp$, and v for puck A in Figure 11.18 just before impact, we obtain a value for the angular momentum of puck A just before the impact that is the same as that of puck B after the impact:

$$L_{A\vartheta,i} = L_{B\vartheta,f} = +r_B mv. \tag{11.37}$$

Because puck A comes to rest after the impact, the change in its angular momentum is $\Delta L_{A\vartheta} = L_{A\vartheta,f} - L_{A\vartheta,i} = 0 - r_B mv = -r_B mv$. The change in the angular momentum of puck B is $\Delta L_{B\vartheta} = L_{B\vartheta,f} - L_{B\vartheta,i} = +r_B mv - 0 = +r_B mv$. As you can readily verify, angular momentum is an extensive quantity (see Section 4.4), and so we can define the angular momentum of the system comprising both pucks as $L_\vartheta = L_{A\vartheta} + L_{B\vartheta}$. Because the change in the angular momentum of one puck is compensated for by the change in the angular momentum of the other puck, the angular momentum of the system does not change in the impact: $\Delta L_\vartheta = 0$.

Figure 11.31 Tangential forces change the angular momentum.

Tangential component changes speed and angular momentum.

Radial component causes centripetal acceleration.

This observation suggests that angular momentum, like momentum, is a conserved quantity. Indeed, if it weren't for friction and air resistance, objects in circular motion would tend to continue their circular motion, just as objects in translational motion tend to continue to move along a straight line (see Section 4.1). The more we reduce friction, the longer a spinning wheel keeps turning. In the absence of friction, it would turn forever and its angular momentum would be constant. Consider, for example, the particle in circular motion shown in **Figure 11.31**. The particle is subject to a force $\vec{F}$ that has both a radial and a tangential component. The radial component keeps the particle moving in circular motion. The tangential component, which is tangent to the circular trajectory and points in the direction opposite the direction of motion, causes the particle to slow down. In the absence of any tangential forces, however, the angular momentum remains constant.

Strictly speaking, the fact that the angular momentum of the colliding pucks in Figure 11.18 remains constant is a consequence of conservation of momentum—the change in the momentum of B is compensated for by a change in the momentum of A. It turns out, however, that conservation of angular momentum is just as fundamental as conservation of momentum and conservation of energy. We can generalize this new conservation law to situations where it cannot be deduced from other conservation principles, which tells us that **conservation of angular momentum** is a fundamental law of physics:

Angular momentum can be transferred from one object to another, but it cannot be created or destroyed.

This means that whenever the angular momentum of an object changes, there must be a compensating change of the opposite sign in the environment.

The angular momentum of an object or system on which no tangential forces are exerted is therefore constant:

$$\Delta L_\vartheta = 0 \quad \text{(no tangential forces)}. \tag{11.38}$$

EXERCISE 11.6 Spinning faster

Divers increase their spin by tucking in their arms and legs (Figure 11.32). Suppose the outstretched body of a diver rotates at 1.2 revolutions per second before he pulls his arms and knees into his chest, reducing his rotational inertia from 9.4 kg·m² to 3.1 kg·m². What is his rotational velocity after he tucks in his arms and legs?

Figure 11.32 Exercise 11.6.

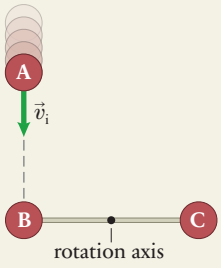
SOLUTION Once the diver is off the board, the only force exerted on him is the gravitational force exerted by Earth. This force does not affect the angular momentum of the diver (dropped objects do not spontaneously start to rotate), and so his angular momentum must remain constant. If his angular momentum before he tucks is $L_{\vartheta,\mathrm{i}}$ and that after is $L_{\vartheta,\mathrm{f}}$, then

$$L_{\vartheta,\mathrm{f}} = L_{\vartheta,\mathrm{i}}$$

and so, from Eq. 11.34,

$$I_{\mathrm{f}}\omega_{\vartheta,\mathrm{f}} = I_{\mathrm{i}}\omega_{\vartheta,\mathrm{i}}$$

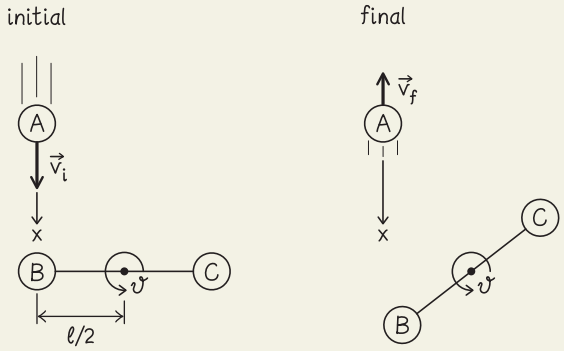
$$\omega_{\vartheta,\mathrm{f}} = \frac{I_{\mathrm{i}}}{I_{\mathrm{f}}}\omega_{\vartheta,\mathrm{i}}$$



$$= \frac{9.4\ \mathrm{kg\cdot m^2}}{3.1\ \mathrm{kg\cdot m^2}}(1.2\ \mathrm{s^{-1}}) = 3.6\ \mathrm{s^{-1}}. \checkmark$$

11.8 Does the rotational kinetic energy of the diver in Exercise 11.6 change as he pulls his arms in? Explain.

EXAMPLE 11.7 Dumbbell collision



In Figure 11.33, two identical pucks B and C, each of inertia m, are connected by a rod of negligible inertia and length ℓ that is free to rotate about a fixed axis through its center. A third identical puck A, initially moving at speed v_{i}, strikes the combination as shown. After the elastic collision, what are the rotational velocity of the dumbbell and the velocity of puck A?

Figure 11.33 Example 11.7.

1 GETTING STARTED I begin with a two-part sketch (Figure 11.34), choosing an x axis in the direction of A's initial motion and choosing counterclockwise as the positive direction of rotation (this is the direction in which I expect the dumbbell to rotate after the collision). Because A hits B head-on and because the inertia of the dumbbell is twice that of A, I expect A to bounce back and move in the negative x direction after the collision, as my after-collision sketch shows.

Figure 11.34

2 DEVISE PLAN In elastic collisions the kinetic energy of the system remains constant (see Section 5.5). In this collision I need to consider the kinetic energy of puck A and the rotational kinetic energy of the dumbbell. Because there are two unknowns—A's final velocity and the dumbbell's final rotational velocity—I need an additional law to determine both. To this end I apply conservation of angular momentum (Eq. 11.38) to the system comprising puck A and the dumbbell.

(Continued)

❸ **EXECUTE PLAN** The initial kinetic energy of the system is that of puck A, $\frac{1}{2}mv_i^2$. The final kinetic energy is the sum of the (translational) final kinetic energy of A and the rotational kinetic energy of the dumbbell, $K_f = \frac{1}{2}mv_f^2 + \frac{1}{2}I\omega_f^2$, where I is the rotational inertia of the dumbbell. Ignoring the negligible inertia of the rod, I can say that each puck in the dumbbell contributes a rotational inertia $m(\ell/2)^2$ given by Eq. 11.30, so that the rotational inertia of the dumbbell is

$$I = 2m(\ell/2)^2 = \tfrac{1}{2}m\ell^2. \qquad (1)$$

Because the collision is elastic, the final kinetic energy must equal the initial kinetic energy, and so

$$\tfrac{1}{2}mv_i^2 = \tfrac{1}{2}mv_f^2 + \tfrac{1}{2}I\omega_f^2 = \tfrac{1}{2}mv_f^2 + \tfrac{1}{2}(\tfrac{1}{2}m\ell^2)\omega_f^2,$$

where I have substituted for I the expression I obtained in Eq. 1. Dividing both sides by $\frac{1}{2}m$ gives $v_i^2 = v_f^2 + \frac{1}{2}\ell^2\omega_f^2$. Because puck A moves along the x axis, $v_i^2 = v_{x,i}^2$ and $v_f^2 = v_{x,f}^2$. Because $\omega_f^2 = \omega_{\vartheta,f}^2$ I get

$$v_{x,i}^2 = v_{x,f}^2 + \tfrac{1}{2}\ell^2\omega_{\vartheta,f}^2. \qquad (2)$$

Next I turn to conservation of angular momentum. The change in A's angular momentum is, from Eq. 11.36,

$$\Delta L_{A\vartheta} = L_{A\vartheta,f} - L_{A\vartheta,i} = (\ell/2)mv_{x,f} - (\ell/2)mv_{x,i}$$
$$= (\ell/2)m(v_{x,f} - v_{x,i}).$$

The initial angular momentum of the dumbbell $L_{d\vartheta,i}$ about the rotation axis is zero; its final angular momentum about this axis is, from Eq. 11.34, $L_{d\vartheta,f} = I\omega_{\vartheta,f}$. The change in the dumbbell's angular momentum is thus

$$\Delta L_{d\vartheta} = I\omega_{\vartheta,f} - 0 = \tfrac{1}{2}m\ell^2\omega_{\vartheta,f}.$$

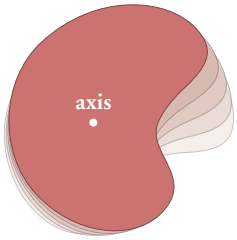
Because the system is isolated, its angular momentum doesn't change (Eq. 11.38), and so

$$\Delta L_\vartheta = \Delta L_{A\vartheta} + \Delta L_{d\vartheta}$$
$$= (\ell/2)m(v_{x,f} - v_{x,i}) + \tfrac{1}{2}m\ell^2\omega_{\vartheta,f} = 0$$

or
$$v_{x,i} = v_{x,f} + \ell\omega_{\vartheta,f}. \qquad (3)$$

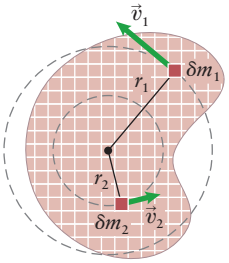
Solving Eq. 3 for $v_{x,f}$, substituting the result into Eq. 2, and using the quadratic equation to solve for the rotational velocity of the dumbbell, I get

$$\omega_{\vartheta,f} = \frac{4v_{x,i}}{3\ell} = +\frac{4v_i}{3\ell}. \checkmark$$



Substituting this result back into Eq. 3, I obtain for the final velocity of puck A $v_{x,f} = -\frac{1}{3}v_{x,i} = -\frac{1}{3}v_i$. ✔

❹ **EVALUATE RESULT** The final rotational velocity is positive, indicating that the dumbbell in Figure 11.34 rotates counterclockwise, in agreement with my drawing. The x component of the final velocity of puck A is negative, indicating that it bounces back, as I expected.



11.9 (*a*) Follow the line of reasoning used in working from Eq. 11.28 to Eq. 11.31 to verify that the rotational inertia of the dumbbell in Example 11.7 is indeed $\frac{1}{2}m\ell^2$. (*b*) Does the momentum of the system remain constant in the collision of Figure 11.33?

Figure 11.35 Procedure for determining the rotational inertia of an extended object.

(*a*) To determine rotational inertia of an extended object . . .

(*b*) . . . divide object into small segments of inertia δm and add up their rotational inertias.

11.6 Rotational inertia of extended objects

We can apply the concept of rotational inertia to extended rigid objects. Consider, for example, the rotating object in **Figure 11.35**. If you imagine breaking down the object into many small segments of equal inertia δm, each segment has a different velocity $\vec{v}$, but all move in circles about the axis at the same rotational speed ω.

The rotational kinetic energy of the rotating object is the sum of the kinetic energies of the segments:

$$K_{rot} = \tfrac{1}{2}\delta m_1 v_1^2 + \tfrac{1}{2}\delta m_2 v_2^2 + \cdots = \sum_n \left(\tfrac{1}{2}\delta m_n v_n^2\right). \qquad (11.39)$$

Because each segment has a different velocity, it is difficult to evaluate this expression. Substituting Eq. 11.11, however, we obtain

$$K_{rot} = \sum_n \left[\tfrac{1}{2}\delta m_n (\omega r_n)^2\right] = \tfrac{1}{2}\left[\sum_n \delta m_n r_n^2\right]\omega^2, \qquad (11.40)$$

where r_n measures the distance from segment n to the rotation axis. Because $\delta m_n r_n^2$ is the rotational inertia I_n of segment n (Eq. 11.30), we can write this expression in the form

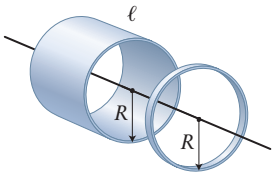
$$K_{rot} = \tfrac{1}{2}\left[\sum_n I_n\right]\omega^2 = \tfrac{1}{2}I\omega^2, \qquad (11.41)$$

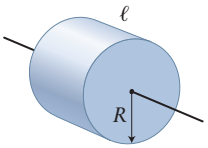
QUANTITATIVE TOOLS

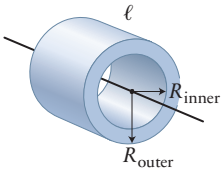
where I is the rotational inertia of the entire object. So, once we know the object's rotational inertia, it is straightforward to calculate its rotational kinetic energy.

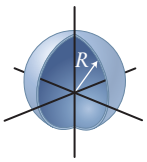
Equations 11.40 and 11.41 show that the rotational inertia of an extended object can be obtained by dividing the object into small segments and computing the sum of the contributions of the small segments:

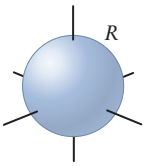
$$I = \sum_n \delta m_n r_n^2. \tag{11.42}$$





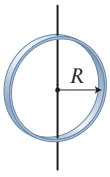


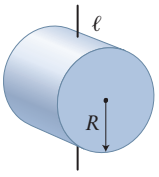


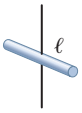


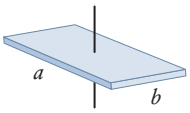
To evaluate this sum for the extended object, we take the limit of this expression as $\delta m_n \to 0$. In this limit, the sum becomes an integral:

$$I = \lim_{\delta m_n \to 0} \sum_n \delta m_n r_n^2 \equiv \int r^2 dm \quad \text{(extended object)}. \tag{11.43}$$









This integral is difficult to evaluate for an arbitrarily shaped object. As the next few examples will show, however, the integral is relatively easy to calculate for objects that exhibit some symmetry and are *uniform* (that is to say, the inertia is uniformly distributed over the volume of the object). **Table 11.3** lists the results of additional calculations.

Table 11.3 Rotational inertia of uniform objects of inertia M about axes through their center of mass

Rotation axes oriented so that object could roll on surface: For these axes, rotational inertia has the form cMR^2, where $c = I/MR^2$ is called the *shape factor*. The farther the object's material from the rotation axis, the larger the shape factor and hence the rotational inertia.

	thin-walled cylinder or hoop	solid cylinder	hollow-core cylinder	thin-walled hollow sphere	solid sphere
Shape					
Rotational inertia	MR^2	$\frac{1}{2}MR^2$	$\frac{1}{2}M(R_{\text{outer}}^2 + R_{\text{inner}}^2)$	$\frac{2}{3}MR^2$	$\frac{2}{5}MR^2$
Shape factor $c = I/MR^2$	1	$\frac{1}{2}$	$\frac{1}{2}\left[1 + \left(\frac{R_{\text{inner}}}{R_{\text{outer}}}\right)^2\right]$	$\frac{2}{3}$	$\frac{2}{5}$

Other axis orientations

	thin-walled hoop	solid cylinder	thin rod	rectangular plate
Shape				
Rotational inertia	$\frac{1}{2}MR^2$	$\frac{1}{4}MR^2 + \frac{1}{12}M\ell^2$	$\frac{1}{12}M\ell^2$	$\frac{1}{12}M(a^2 + b^2)$

EXAMPLE 11.8 Rotational inertia of a hoop about an axis through its center

Calculate the rotational inertia of a hoop of inertia m and radius R about an axis perpendicular to the plane of the hoop and passing through its center.

❶ **GETTING STARTED** I begin by drawing the hoop and a coordinate system (**Figure 11.36**). Because the axis goes through the center of the hoop, I let the origin be at that location. The axis of rotation is perpendicular to the plane of the drawing and passes through the origin.

Figure 11.36

❷ **DEVISE PLAN** Equation 11.43 gives the rotational inertia of an object as the sum of the contributions from many small segments. If I divide the hoop into infinitesimally small segments each of inertia dm, I see that each segment lies the same distance $r = R$ from the rotation axis (one such segment is shown in Figure 11.36). This means I can pull the constant $r^2 = R^2$ out of the integral in Eq. 11.43, making it easy to calculate.

❸ **EXECUTE PLAN** Substituting $r = R$ in Eq. 11.43, I obtain

$$I = \int r^2\, dm = R^2 \int dm = mR^2. \checkmark$$

❹ **EVALUATE RESULT** This result makes sense because all the material contained in the hoop lies at the same distance R from the rotation axis. Therefore the rotational inertia of the hoop is the same as that of a particle of inertia m located a distance R from the rotation axis, which I know from Eq. 11.30: $I = mR^2$.

For objects in which not all the material is the same distance from the rotation axis, we need to express dm in terms of either Cartesian or polar coordinates in order to evaluate the integral in Eq. 11.43. For uniform one-dimensional objects, we place the object along a positive x axis and introduce a new quantity: *inertia per unit length* $\lambda \equiv dm/dx$. Each small segment dm of the object can then be written as the product of λ and an infinitesimal length dx: $dm = \lambda\, dx$. Equation 11.43 thus becomes, after substituting x for r,

$$I = \lambda \int x^2 dx \quad \text{(uniform one-dimensional object)}, \qquad (11.44)$$

where the integration is carried out over the length of the object.

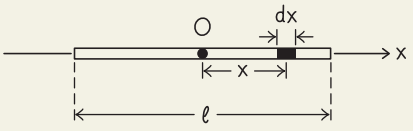
Likewise, for a uniform two-dimensional object, we convert dm to a surface area by defining an *inertia per unit area* $\sigma \equiv dm/dA$, so that Eq. 11.43 becomes

$$I = \sigma \int r^2 da \quad \text{(uniform two-dimensional object)}, \qquad (11.45)$$

where the integration is carried out over the surface area of the object.

For a uniform three-dimensional object, we introduce an *inertia per unit volume* $\rho \equiv dm/dV$, so that Eq. 11.43 becomes

$$I = \rho \int r^2 dV \quad \text{(uniform three-dimensional object)}, \qquad (11.46)$$



where the integration is carried out over the volume of the object.

EXAMPLE 11.9 Rotational inertia of a rod about an axis through its center

Calculate the rotational inertia of a uniform solid rod of inertia m and length ℓ about an axis perpendicular to the long axis of the rod and passing through its center.

❶ **GETTING STARTED** I begin with a sketch of the rod. For this one-dimensional object, I choose an x axis that lies along the rod's long axis, and because the rotation being analyzed is about a rotation axis located through the rod's center, I choose this point for the origin of my x axis (**Figure 11.37**).

Figure 11.37

❷ **DEVISE PLAN** Because the rod is a uniform one-dimensional object, I can use Eq. 11.44 to calculate its rotational

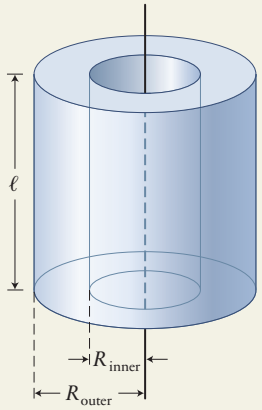
QUANTITATIVE TOOLS

inertia. First I determine the inertia per unit length λ. Then I carry out the integration from one end of the rod ($x = -\ell/2$) to the other ($x = +\ell/2$).

❸ **EXECUTE PLAN** The inertia per unit length is $\lambda = m/\ell$. Substituting this expression and the integration boundaries into Eq. 11.44, I get

$$I = \lambda \int x^2 dx = \frac{m}{\ell} \int_{-\ell/2}^{+\ell/2} x^2 dx = \frac{m}{\ell}\left[\frac{x^3}{3}\right]_{-\ell/2}^{+\ell/2} = \tfrac{1}{12} m\ell^2. \checkmark$$

❹ **EVALUATE RESULT** If I approximate each half of the rod as a particle located a distance $\ell/4$ from the origin I chose in Figure 11.37, the rotational inertia of the rod would be, from Eq. 11.30, $2(\frac{1}{2}m)(\frac{1}{4}\ell)^2 = \frac{1}{16}m\ell^2$. This is not too far from the value I obtained, so my answer appears to be reasonable.



11.10 Calculate the rotational inertia of the rod in Example 11.9 about an axis perpendicular to the long axis of the rod and passing through one end.

EXAMPLE 11.10 Rotational inertia of a hollow-core cylinder

Calculate the rotational inertia of a uniform hollow-core cylinder of inner radius R_{inner}, outer radius R_{outer}, length ℓ, and inertia m about an axis parallel to the cylinder's length and passing through its center, as in **Figure 11.38**.

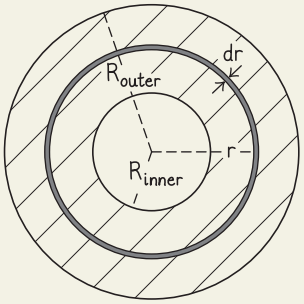


Figure 11.38 Example 11.10.

❶ **GETTING STARTED** As in Example 11.9, I will divide this cylinder into segments and integrate the contributions of all the segments over the volume of the cylinder. There are many ways to divide the cylinder into small segments dm, but I can simplify the integration by exploiting the cylindrical symmetry. Starting at the inner face of the wall, at R_{inner}, and moving toward the outer face, at R_{outer}, I divide the wall into a series of many thin-walled cylindrical shells, each of thickness dr and length ℓ and all concentric with the original cylinder, as shown in my top-down sketch of the cylinder (**Figure 11.39**). Because each shell is infinitely thin, all the material in each shell is the same distance r from the axis of rotation, which simplifies the calculation.

❷ **DEVISE PLAN** The hollow-core cylinder is a uniform, three-dimensional object, so I should use Eq. 11.46. First, I must determine the inertia per unit volume, m/V, for it. Next, I must express the infinitesimal volume dV of each shell in terms of r and dr. Finally, I should carry out the integration for values of r from R_{inner} to R_{outer}.

Figure 11.39

❸ **EXECUTE PLAN** Each thin-walled shell has an inertia $dm = \rho\, dV$, where ρ is inertia per unit volume and dV is the volume of the shell. To determine $\rho = m/V$ for the cylinder, I divide its inertia m by its volume V. The volume of the solid part of the cylinder plus the empty space that forms its core is $\pi R_{\text{outer}}^2 \ell$ and that of the core is $\pi R_{\text{inner}}^2 \ell$. So the volume of the cylinder is $V = \pi(R_{\text{outer}}^2 - R_{\text{inner}}^2)\ell$, and $\rho = m/\pi(R_{\text{outer}}^2 - R_{\text{inner}}^2)\ell$.

Each shell has an outer surface area of $2\pi r\ell$ and thickness dr, and so its volume is $dV = 2\pi r\ell\, dr$. The rotational inertia of the entire cylinder is thus

$$I = \rho \int r^2 dV = \rho \int_{R_{\text{inner}}}^{R_{\text{outer}}} r^2 (2\pi r\ell) dr = 2\pi\rho\ell \int_{R_{\text{inner}}}^{R_{\text{outer}}} r^3 dr.$$

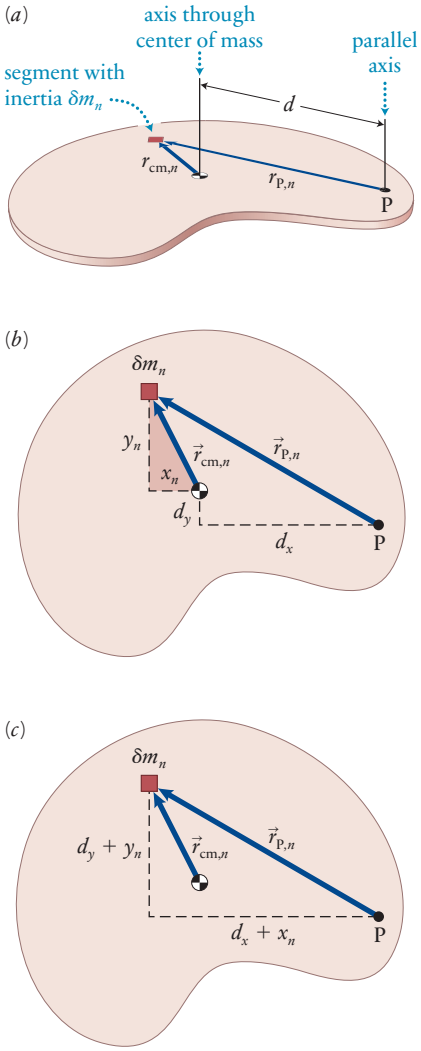
Working out the integral, I get

$$I = 2\pi\rho\ell\left[\frac{r^4}{4}\right]_{R_{\text{inner}}}^{R_{\text{outer}}} = \frac{\pi\rho\ell(R_{\text{outer}}^4 - R_{\text{inner}}^4)}{2}$$

$$= \frac{\pi\ell(R_{\text{outer}}^4 - R_{\text{inner}}^4)}{2} \frac{m}{\pi\ell(R_{\text{outer}}^2 - R_{\text{inner}}^2)}.$$

Factoring $R_{\text{outer}}^4 - R_{\text{inner}}^4 = (R_{\text{outer}}^2 + R_{\text{inner}}^2)(R_{\text{outer}}^2 - R_{\text{inner}}^2)$, I get for the rotational inertia of the hollow-core cylinder

$$I_{\text{hollow-core cylinder}} = \tfrac{1}{2} m(R_{\text{outer}}^2 + R_{\text{inner}}^2). \checkmark$$



❹ **EVALUATE RESULT** In the limit $R_{\text{inner}} = R_{\text{outer}}$, the cylinder becomes a thin-walled cylindrical shell of radius R_{outer}, and my result becomes $I = mR_{\text{outer}}^2$, as I expect for an object that has all its material a distance R from the axis of rotation.

The result from Example 11.10 allows us to determine the rotational inertia of a solid cylinder by setting R_{inner} equal to zero and R_{outer} equal to the radius R of the cylinder. About the long axis of the cylinder, we have

$$I_{\text{solid cylinder}} = \tfrac{1}{2}mR^2. \tag{11.47}$$

11.11 Note in Example 11.10 that the rotational inertia of a thick cylindrical shell is $\frac{1}{2}m(R_{\text{outer}}^2 + R_{\text{inner}}^2)$ while that of a solid cylinder is $\frac{1}{2}mR_{\text{outer}}^2$. Does the fact that the factor $R_{\text{outer}}^2 + R_{\text{inner}}^2$ is larger than the factor R_{outer}^2 mean that you can increase the rotational inertia of a solid cylinder by drilling a hole through it?

Figure 11.40 The parallel-axis theorem relates the rotational inertia about an axis through the center of mass to the rotational inertia about other parallel axes.

Because rotational inertia depends on the location of the rotation axis, tables such as Table 11.3 may seem to be of limited utility. However, there is a simple relationship between the rotational inertia of an object about an axis through its center of mass and its rotational inertia about any axis parallel to the center-of-mass axis. Consider the object shown in **Figure 11.40**. Let us derive an expression relating the rotational inertia of the object about an axis through its center of mass to the rotational inertia about a parallel axis through an arbitrary point P.

According to Eq. 11.42, the rotational inertia of the object about an axis through its center of mass is

$$I_{\text{cm}} = \sum_n \delta m_n r_{\text{cm},n}^2 = \sum_n \delta m_n (x_n^2 + y_n^2), \tag{11.48}$$

where I have used the Pythagorean theorem for the shaded right triangle in Figure 11.40*b* to substitute for $r_{\text{cm},n}^2$. The rotational inertia about a parallel axis through P a distance d away from the center of mass is

$$I = \sum_n \delta m_n r_{\text{P},n}^2 = \sum_n \delta m_n[(d_x + x_n)^2 + (d_y + y_n)^2], \tag{11.49}$$

where now the Pythagorean substituting comes from the right triangle in Figure 11.40*c*. Working out the right side, I obtain

$$I = \sum_n \delta m_n(d_x^2 + 2d_x x_n + x_n^2 + d_y^2 + 2d_y y_n + y_n^2). \tag{11.50}$$

From the definition of the center of mass (Eq. 6.24), I know that if the center of mass is at the origin, then

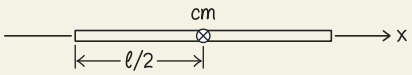
$$\sum_n \delta m_n\, x_n = \sum_n \delta m_n y_n = 0, \tag{11.51}$$

and because d_x and d_y are constant, the terms that contain $2d_x x_n$ and $2d_y y_n$ drop out of Eq. 11.50, leaving me with

$$I = \sum_n \delta m_n[(d_x^2 + d_y^2) + (x_n^2 + y_n^2)] = \sum_n \delta m_n d^2 + I_{\text{cm}}. \tag{11.52}$$

The factor d^2 can be pulled out of the summation, and so we see that the rotational inertia about the parallel axis is

$$I = I_{\text{cm}} + md^2. \tag{11.53}$$



This relationship is called the **parallel-axis theorem.**

EXAMPLE 11.11 Rotational inertia of a rod about an axis through one end

Use the parallel-axis theorem to calculate the rotational inertia of a uniform solid rod of inertia m and length ℓ about an axis perpendicular to the length of the rod and passing through one end.

❶ **GETTING STARTED** I first make a sketch of the rod, showing its center of mass and the location of the rotational axis (**Figure 11.41**). Because I am told to use the parallel-axis theorem, I know I have to work with the rod's center of mass. I know that for a uniform rod, the center of mass coincides with the geometric center, and so I mark that location in my sketch.

Figure 11.41 A solid rod of length ℓ rotating about an axis at one end.

❷ **DEVISE PLAN** In Example 11.9, I determined that the rotational inertia about an axis through the rod's center is $I = \frac{1}{12}m\ell^2$. For a uniform rod, the center of mass coincides with the geometric center, so I can use Eq. 11.53 to determine the rotational inertia about a parallel axis through one end.

❸ **EXECUTE PLAN** The distance between the rotation axis and the center of mass is $d = \frac{1}{2}\ell$, and so, with $I_{cm} = \frac{1}{12}m\ell^2$ from Example 11.9, Eq. 11.53 yields

$$I = I_{cm} + md^2 = \tfrac{1}{12}m\ell^2 + m\left(\frac{\ell}{2}\right)^2 = \tfrac{1}{3}m\ell^2. \checkmark$$

❹ **EVALUATE RESULT** I obtained the same answer in Checkpoint 11.10 by directly working out the integral.

11.12 About what axis is the rotational inertia of an extended object smallest?

Chapter Summary

Rotational kinematics (Sections 11.1, 11.2, 11.4)

Concepts During **rotational motion,** all the particles in an object follow circular paths around the *axis of rotation*.

The **rotational velocity** ω_ϑ of an object is the rate at which the object's rotational coordinate ϑ changes.

The **rotational acceleration** α_ϑ is the rate at which an object's rotational velocity changes.

Quantitative Tools When an object travels a distance s along the circumference of a circle of radius r, the object's **rotational coordinate** ϑ is a unitless quantity defined as s divided by the circle's radius:

$$\vartheta \equiv \frac{s}{r}. \tag{11.1}$$

The arc distance s is measured from the positive x axis. To measure ϑ we need to choose a direction of increasing ϑ and a zero, just as we need to specify a direction of increasing x and an origin to measure position along an axis.

For any rotating object, the rotational velocity and rotational acceleration are

$$\omega_\vartheta = \frac{d\vartheta}{dt} \tag{11.6}$$

$$\alpha_\vartheta = \frac{d\omega_\vartheta}{dt} = \frac{d^2\vartheta}{dt^2}. \tag{11.12}$$

Translational variables for rotating objects (Sections 11.1, 11.4)

Concepts The velocity $\vec{v}$ of an object moving along a circle is always perpendicular to the object's position vector $\vec{r}$ measured from the axis of rotation.

The tangential component v_t of the velocity is tangent to the circle. The radial component v_r of the velocity is zero.

An object moving in a circle has a nonzero acceleration (even if its speed is constant) because the direction of the velocity changes.

An inward force is required to make an object move in a circle, even at constant speed.

Quantitative Tools The tangential and radial components of the velocity of an object moving along a circular path are

$$v_t = r\omega_\vartheta \tag{11.10}$$

$$v_r = 0. \tag{11.18}$$

The radial component of the acceleration is

$$a_r = -\frac{v^2}{r}. \tag{11.16}$$

This radial component is called the **centripetal acceleration** and is directed toward the center of the circle. It can also be written as

$$a_r = -r\omega^2.$$

The tangential component of the acceleration is

$$a_t = r\alpha_\vartheta. \tag{11.23}$$

The magnitude of the acceleration is

$$a = \sqrt{a_r^2 + a_t^2}. \tag{11.21}$$

Constant rotational acceleration (Section 11.4)

Concepts If the tangential acceleration a_t of a rotating object is constant, its rotational acceleration α_ϑ is also constant. In only that case, the rotational kinematics relationships for *constant rotational acceleration* apply.

Quantitative Tools If an object with constant rotational acceleration α_ϑ initially has a rotational coordinate ϑ_i and a rotational velocity $\omega_{\vartheta,\mathrm{i}}$, then after a time interval Δt its rotational coordinate and rotational velocity are

$$\vartheta_\mathrm{f} = \vartheta_\mathrm{i} + \omega_{\vartheta,\mathrm{i}}\Delta\mathrm{t} + \tfrac{1}{2}\alpha_\vartheta(\Delta t)^2 \tag{11.26}$$

$$\omega_{\vartheta,\mathrm{f}} = \omega_{\vartheta,\mathrm{i}} + \alpha_\vartheta\Delta t. \tag{11.27}$$

Rotational inertia (Sections 11.3, 11.5, 11.6)

Concepts **Rotational inertia** is a measure of an object's tendency to resist any change in its rotational velocity. The rotational inertia depends on the inertia of the object and on how that inertia is distributed. The SI units of rotational inertia are kilograms-meters-squared $(\mathrm{kg \cdot m^2})$.

Quantitative Tools The rotational inertia I of a rotating particle of inertia m is

$$I = mr^2, \tag{11.30}$$

where r is the distance from the particle to the rotation axis. For an extended object, the rotational inertia is

$$I = \int r^2 dm. \tag{11.43}$$

The **parallel-axis theorem:** If I_{cm} is the rotational inertia of an object of inertia m about an axis A through the object's center of mass, the rotational inertia I of the object about an axis parallel to A and a distance d away from A is

$$I = I_{cm} + md^2. \tag{11.53}$$

Rotational kinetic energy and angular momentum (Section 11.5)

Concepts **Rotational kinetic energy** is the kinetic energy of an object due to its rotational motion.

Angular momentum L_ϑ is the capacity of an object to make other objects rotate.

A particle can have angular momentum even if it is not rotating.

The law of **conservation of angular momentum** says that angular momentum can be transferred from one object to another but cannot be created or destroyed. The angular momentum of an object or system is constant when no tangential forces are exerted on it.

Quantitative Tools The rotational kinetic energy of an object that has rotational inertia I and rotational speed ω is

$$K_{rot} = \tfrac{1}{2} I\omega^2. \tag{11.31}$$

The angular momentum of an object that has rotational inertia I and rotational velocity ω_ϑ is

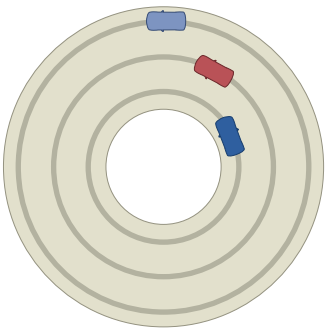
$$L_\vartheta = I\omega_\vartheta. \tag{11.34}$$

The angular momentum of a particle of inertia m and speed v about an axis of rotation is

$$L = r_\perp mv, \tag{11.36}$$

where $r_\perp$ is the perpendicular distance from the axis to the line of action of the particle's momentum. The distance $r_\perp$ is called the **lever arm distance** of the momentum relative to the axis.

Questions and Problems



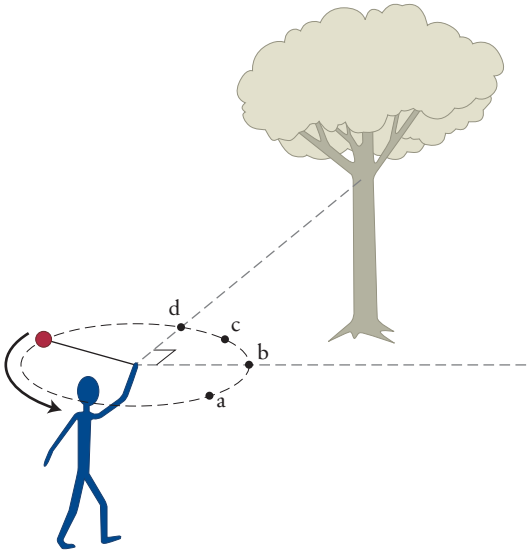
For instructor-assigned homework, go to Mastering Physics

Dots indicate difficulty level of problems: • = *easy*, •• = *intermediate*, ••• = *hard*; CR = *context-rich problem.*

11.1 Circular motion at constant speed

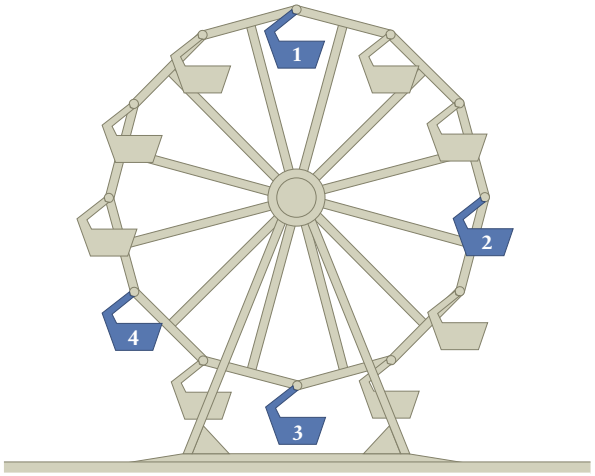
1. For a given level of technology, there is a maximum density of "bits" of information that can be stored on a computer's hard-drive disk. The data are stored in a tight spiral, so that "tracks" are essentially circles of increasing radius from inner to outer parts of the disk. As the disk spins at a constant rate, data are read at a constant rate regardless of the radius of the track being read. Which determines the disk capacity: the innermost track or the outermost track? •
2. What is the ratio of the rotational speed of Earth's daily rotation to that of its annual revolution? •
3. When one race car passes another during a race, the passing car usually tries to pass on the inner lane of a curve in the track. Why? •
4. The toy race track in Figure P11.4 has three lanes, and cars cannot change lanes. The centerlines of any two adjacent lanes are 100 mm apart, and the innermost lane has a radius of 1.00 m. (*a*) If each car has the same average speed, compare the time intervals needed for the cars to complete 20 laps. (*b*) If all three cars start beside each other and finish the race at the same instant, how do their average speeds compare? ••

Figure P11.4



5. Plot, as a function of time, the rotational velocity of your car's wheels as you (*a*) back out of your driveway, (*b*) drive down a residential street, (*c*) turn onto a highway, (*d*) drive on the highway for a while, (*e*) exit the highway and stop at a traffic light, (*f*) drive on a city street, and (*g*) park at your favorite Chinese restaurant. ••
6. Hold a quarter down flat on a table with a finger. Then place a second quarter flat on the table, touching one point on the edge of the first quarter. If you roll the second quarter around the first so that the edges do not slip, describe the revolution and rotation as the second quarter returns to its original location on the table. •••

11.2 Forces and circular motion

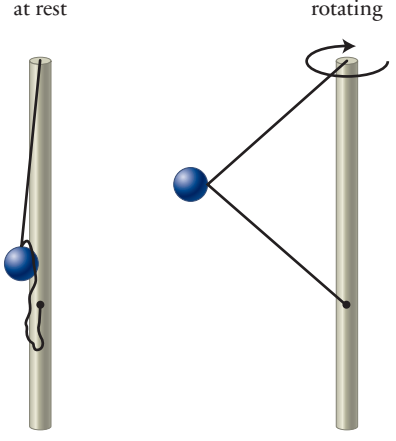


7. Suppose the expression for centripetal acceleration is of the form $a_c = v^p r^q$, where p and q are constants. By analyzing the units in this expression, determine the numerical values of p and q. •
8. Standing in front of a tree, you whirl your sling with a rock in it. If you wish to hit the tree, at what location in the circle in Figure P11.8 (nearest point a, b, c, or d) should you release the rock from the sling? •

Figure P11.8

9. The Ferris wheel in Figure P11.9 is turning at constant speed. Draw and label free-body diagrams showing the forces on passengers at the numbered positions. Be careful to show correct relative lengths on your vector arrows. •

Figure P11.9



10. To see some of the trouble you can get into with noninertial reference frames, try this experiment. You and a friend stand opposite each other on the edge of a playground merry-go-round and get it rotating. While it is rotating, you attempt to toss a ball to your friend. As seen from above, what does the path of the ball look like (*a*) to an observer standing at the top of a nearby slide, (*b*) to you, and (*c*) to your friend? (*d*) If you did not know you were in a rotating reference frame, how would you explain the path of the ball in part *b*? ••
11. A salad spinner (Figure P11.11) is used to dry lettuce that has been washed. What physics is going on as the spinner does its job? ••

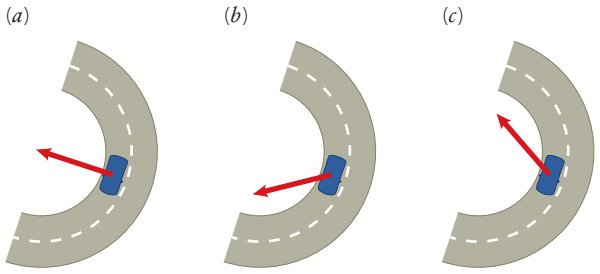
Figure P11.11

12. A race car is negotiating a curve on a banked track. There is a certain speed $v_{critical}$ at which friction is not needed to keep the car on the track in the curve. (This is the speed the car should travel if there is an oil slick on the track, for example.) Draw a free-body diagram showing the forces exerted on the car when it is moving at speed (*a*) $v = v_{critical}$, (*b*) $v > v_{critical}$, and (*c*) $v < v_{critical}$. ••
13. In a certain elaborate roller coaster, the cars are not on tracks but inside a U-shaped track much like a bobsled run. The cars are thus free to swing left and right across the U, climbing the walls as they do so. A student on the ride holds a string with a chunk of metal tied to the free end, with the chunk dangling between his knees as the ride begins. When the car enters a tight left turn, does the chunk swing toward the student's left knee, toward his right knee, or in some other direction? Ignore any friction between cars and track. ••
14. The ball in Figure P11.14 is attached to a vertical rod by two strings of equal strength (able to support much more than one of these balls) and equal length. The strings are

Figure P11.14

light and do not stretch. The rod begins to rotate with its rotational speed increasing slowly, causing the ball to revolve with slowly increasing speed. (*a*) Which string breaks first? (*b*) To justify your answer to part *a*, draw a free-body diagram for the ball, indicating all forces exerted on it and their relative magnitudes. ●●

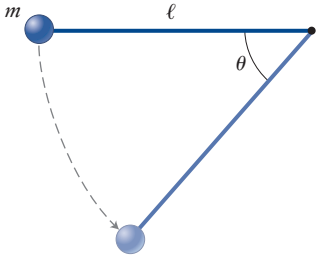
15. Suppose that you were to tie a heavy metal washer to one end of a string, hold the string by the other end, and whirl it in a horizontal circle above your head. Pay close attention to where your hand would be and to where the washer would be as you speed up the rotation. Ignore air resistance. (*a*) Draw the motion of your hand and the motion of the washer. At a given instant, draw the location of the washer and your hand and the string between them. (*b*) As you speed up the rotation, what force is responsible for the acceleration of the washer? Is there a tangential component to this acceleration? A radial component? (*c*) When the washer achieves some given rotational speed, you cease increasing that speed. Describe the motion of your hand now. ●●●



11.3 Rotational inertia

16. Floor lamps usually have a base with large inertia, while the long body and top have much less inertia. If you want to show off by spinning a floor lamp like a baton, where should you grab the lamp? ●
17. A gymnast's backflip is considered more difficult to do in the layout (straight body) position than in the tucked position. Why? ●
18. An ice cube and a rubber ball are both placed at one end of a warm cookie sheet, and the sheet is then tipped up. The ice cube slides down with virtually no friction, and the ball rolls down without slipping. If the ball and the ice cube have the same inertia, which one reaches the bottom first? ●
19. (*a*) Is there a choice of rotation axes for a bowling ball and a baseball, each rotating on its own axis, such that the baseball has a greater rotational inertia? If so, describe the axes. If not, explain why not. (*b*) Repeat for a revolving bowling ball and a revolving baseball. ●●
20. You are designing a uniform thin rectangular door to fill a 1 m wide × 2 m tall opening, and you want it to be easy to open. (*a*) Considering only vertical and horizontal axes, what placement of the axis of rotation would result in the smallest rotational inertia? (*b*) Is such an axis practical? ●●
21. You stand on the edge of a playground carousel while your friends help you get it going. After they stop pushing, you walk toward the center. (*a*) What happens to the rotational inertia of the carousel-you system as you move inward from the edge? (*b*) How does this change in rotational inertia affect the motion of the carousel? ●●

11.4 Rotational kinematics

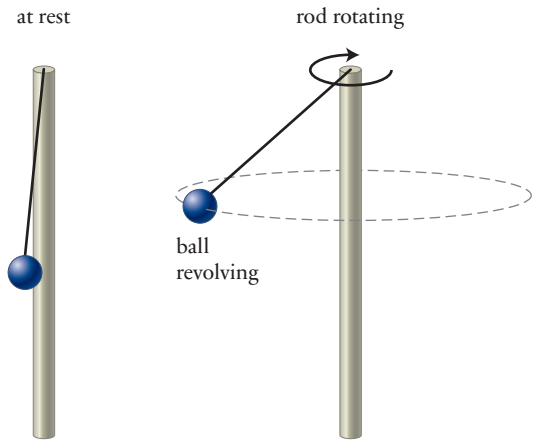


22. A car's engine is turning the crankshaft at 6000 rev/min. What is the rotational speed ω? ●
23. What is the rotational speed of a watch's second hand? Its hour hand? ●
24. If your tires are worn, does your odometer (which is keyed to the turns of the axle) underestimate or overestimate the number of miles you drive? ●
25. Moving at its maximum safe speed, an amusement park carousel takes 12 s to complete a revolution. At the end of the ride, it slows down smoothly, taking 2.5 rev to come to a stop. What is the magnitude of the rotational acceleration of the carousel while it is slowing down? ●●
26. You have a weekend job selecting speed limit signs to put at road curves. The speed limit is determined by the radius of the curve and the bank angle. For a turn of radius 400 m and a 7.0° bank angle, what speed limit should you post so that a car traveling at that speed negotiates the turn successfully even when the road is wet and slick? ●●
27. As you drive clockwise around a turn (as viewed from overhead), you see backed-up traffic ahead and so you slow down. Which force diagram in Figure P11.27 best illustrates your acceleration? ●●

Figure P11.27

28. At the end of a ride, a carnival carousel decelerates smoothly from some initial rotational speed ω to a stop. (*a*) Plot, as a function of time, the speed v of a carousel horse at radius R and of another horse at radius $2R$. (*b*) Plot the magnitude of the centripetal acceleration of the two horses as a function of time. ●●
29. You attach one end of a string of length ℓ to a small ball of inertia m. You attach the string's other end to a pivot that allows free revolution. You hold the ball out to the side with the string taut along a horizontal line, as in Figure P11.29. (*a*) If you release the ball from rest, what is the tension $\mathcal{T}$ in the string as a function of the angle θ swept through? (*b*) What maximum tension should the string be able to sustain if you want it not to break through the ball's entire motion? ●●

Figure P11.29



30. A pendulum is made of a bob dangling from a lightweight string of length ℓ. The bob is pulled sideways so that the string makes an angle θ_i with respect to the vertical, then released. As it swings down, what is the rotational speed of the bob as a function of the changing angle θ? ●●

31. Assume that Earth's orbit around the Sun is a perfect circle. Earth's inertia is 5.97×10^{24} kg, the radius of its orbit is 1.50×10^{11} m, and its orbital period is 365.26 days. (*a*) What is the magnitude of its centripetal acceleration around the Sun? (*b*) What are the magnitude and direction of the force necessary to cause this acceleration? ●●

32. A ball is suspended by a string from the top of a vertical rod as shown in Figure P11.32. The rod starts at rest and then begins to rotate with a small constant rotational acceleration. Qualitatively plot as a function of time the magnitude of (*a*) the vertical component and (*b*) the horizontal component of the tensile force exerted on the ball by the string. ●●

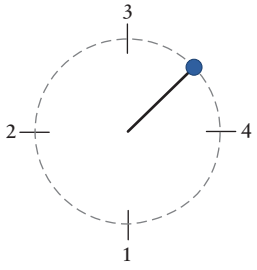


Figure P11.32

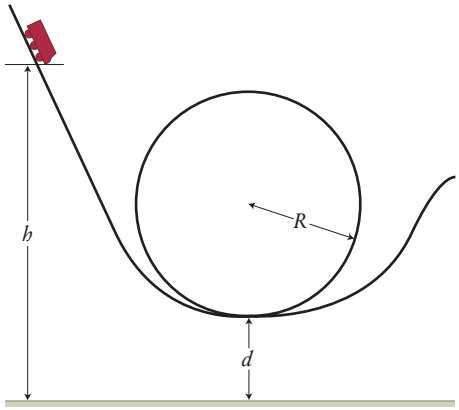
33. You hold a small ice cube near the top edge of a hemispherical bowl of radius 100 mm. When you release the cube from rest, what is the magnitude of its acceleration at the instant it reaches the bottom of the bowl? Ignore friction. ●●

34. A 0.100-kg ball attached to a 0.20-m rod of very small inertia moves in a vertical circle in such a way that its speed remains constant. Let $\mathcal{T}_1$, $\mathcal{T}_2$, $\mathcal{T}_3$, and $\mathcal{T}_4$ be the tensions in the rod at positions 1, 2, 3, and 4 in Figure P11.34. (*a*) Rank the tensions in order of magnitude, greatest first. (*b*) What rotational speed is required at position 3 to keep $\mathcal{T}_3$ barely greater than zero? (*c*) At that speed, what is the tension at position 1? ●●

Figure P11.34

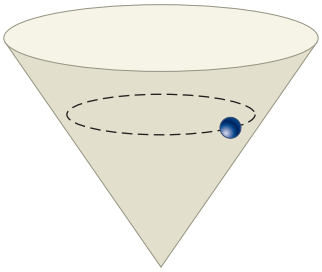


35. An automobile accelerates from rest at $t = 0$ such that its tires undergo a constant rotational acceleration $\alpha = 5.2\ \text{s}^{-2}$. The radius of each tire is 0.38 m. At $t = 10$ s, compute (*a*) the rotational speed ω of the tires, (*b*) the rotational displacement $\Delta\vartheta$ of each tire, (*c*) the speed v of the automobile (assuming the tires stay perfectly round), and (*d*) the distance it has traveled. ●●

36. For the tread on your car tires, which is greater: the tangential acceleration when going from rest to highway speed as quickly as possible or the centripetal acceleration at highway speed? ●●

37. A roller-coaster car initially at a position on the track a height h above the ground begins a downward run on a long, steeply sloping track and then goes into a circular loop-the-loop of radius R whose bottom is a distance d above the ground (Figure P11.37). Ignore friction. (*a*) What is the car's speed when it reaches the bottom of the loop? (*b*) What is the magnitude of the normal force exerted on the car at that instant? (*c*) What is its speed when its position is one-quarter of the way around the loop? (*d*) What is the magnitude of the normal force exerted on it at the one-quarter position? (*e*) What is the car's acceleration at the one-quarter position? ●●●

Figure P11.37

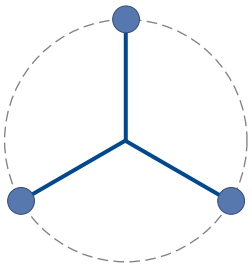


38. (*a*) Consider a circular vertical loop-the-loop on a roller coaster. Show that if a car coasts without power around the loop, the difference between the normal force exerted by the car on a passenger at the top of the loop and the normal force exerted by the car on her at the bottom of the loop is six times the gravitational force exerted on her. (*b*) This difference of $6mg$, referred to as "six gees," is quite a difference for the body to tolerate. To avoid this stress, vertical loops are teardrop-shaped rather than circular, designed so that the centripetal acceleration is constant all around the loop. How must the radius of curvature R change as the car's height h above the ground increases in order to have this constant centripetal acceleration? Express your answer as a function: $R = R(h)$. ●●●

39. A ball is put into a cone and made to move at a constant speed of 3.00 m/s in a horizontal circle of radius 0.500 m (Figure P11.39). (*a*) What is the centripetal component of the ball's acceleration? (*b*) What is the tangential component of its acceleration? (*c*) What force counteracts the force of gravity to keep the ball moving in a horizontal circle? (*d*) Use these insights to determine the height h at which the ball is circling above the bottom of the cone.

[Hint: This is equivalent to determining the angle the cone makes with its vertical axis.] •••

Figure P11.39



40. A race car driving on a banked track that makes an angle θ with the horizontal rounds a curve for which the radius of curvature is R. (*a*) As described in Problem 12, there is one speed v_{critical} at which friction is not needed to keep the car on the track. What is that speed in terms of θ and R? (*b*) If the coefficient of friction between tires and road is μ, what maximum speed can the car have without going into a skid when taking the curve? •••

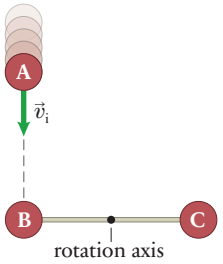
11.5 Angular momentum

41. A 0.25-kg ball attached to a string is being spun around on a horizontal surface at a rotational speed of 2.5 rev/s. What is the ball's kinetic energy if the string is 1.0 m long? •

42. Three small, identical 1.0-kg pucks are attached to identical 0.50-m strings, tied together at a common center as shown in Figure P11.42. When whirled in circular motion at angular speed 3.0 s^{-1}, what are (*a*) the rotational kinetic energy and (*b*) the magnitude of the angular momentum about the common center? •

Figure P11.42

43. As you stand on the sidewalk outside an apartment building, a 1.0-kg bird flies toward you at 1.5 m/s along a straight line that passes 2.0 m above your head and runs parallel to the street. A friend is reclining with his head 6.0 m directly above your head, watching from a balcony. (*a*) What magnitude of the angular momentum do you observe the bird to have, using your head as a reference point? (*b*) What magnitude of the angular momentum does your friend observe the bird to have, using his own head as a reference point? •



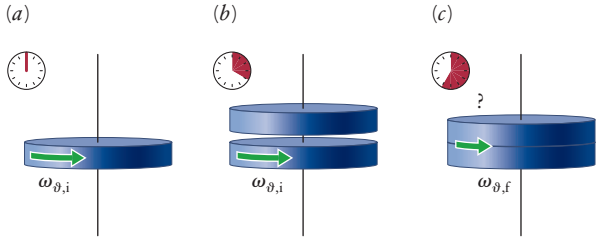
44. Puck A, of inertia m, is attached to one end of a string of length ℓ, and the other end of the string is attached to a pivot so that the puck is free to revolve on a smooth horizontal surface. Puck B, of inertia $8m$, is attached to one end of a string of length $\ell/2$, and the other end of the string is attached to a second pivot so that B is also free to revolve. In each case, the puck is held as far as possible from the pivot so that the string is taut and then given an initial velocity $\vec{v}$ perpendicular to the string. (*a*) How does the magnitude of the angular momentum of puck A about its pivot compare with that of puck B about its pivot? (*b*) How does the rotational kinetic energy of A compare with that of B? ••

45. You have a pail of water with a rope tied to the handle. If you whirl the pail in a vertical circle fast enough, none of the water spills out, even when the pail is upside down. Explain why. ••

46. Consider the roller-coaster car in Problem 37. At what minimum value of the starting height h above the ground must the car begin its journey if it is to remain on the track at the top of the loop? ••

47. In Figure P11.47, two identical pucks B and C, each of inertia m, are connected by a rod of length ℓ and negligible inertia that is free to rotate about its center. Then puck A, of initial speed v_i and inertia $m/2$, comes in and hits B. After the collision, in which no energy is dissipated, what are (*a*) the rotational speed of the dumbbell and (*b*) the velocity $\vec{v}$ of A? ••

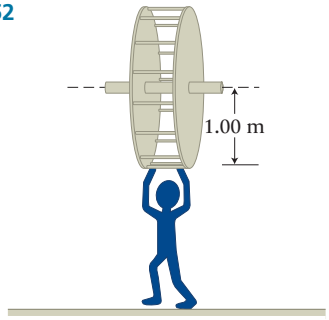
Figure P11.47



48. A small puck on an air table revolves in a circle with rotational speed ω, held at radius r by a weighted string that passes through a hole in the table. You slowly pull down on the weighted end of the string, decreasing the radius r. Assume that the angular momentum of the puck about the hole remains constant. (*a*) What is the rotational speed when half the string has been taken up? (*b*) What has happened to the speed v during this time interval? ••

49. Two skaters skate toward each other, each moving at 3.3 m/s. Their lines of motion are separated by a perpendicular distance of 2.0 m. Just as they pass each other (still 2.0 m apart), they link hands and spin about their common center of mass. What is the rotational speed of the couple about the center of mass? Treat each skater as a particle, one with an inertia of 75 kg and the other with an inertia of 48 kg. ••

50. A record player turntable initially rotating at $33\frac{1}{3}$ rev/min is braked to a stop at a constant rotational acceleration. The turntable has a rotational inertia of 0.020 kg · m^2. When it is switched off, it slows down to 75% of its initial rotational speed in 5.0 s. (*a*) How long does it take to come to rest? (*b*) How much work has to be done on the turntable to bring it to rest? ••



51. A disk of rotational inertia I about the central axis shown in Figure P11.51 is rotating about this axis with initial rotational velocity $\omega_{\vartheta,\mathrm{i}}$ on low-friction bearings. A second identical disk is held at rest a few millimeters directly above the first disk and suddenly dropped. After some slipping, the two discs are observed to have a common rotational speed about the original axis of rotation. What is the magnitude of the final rotational velocity of the combined disks? ••

Figure P11.51

52. A popular ride at some playgrounds consists of two circular disks joined by rungs (Figure P11.52). The center of the unit is attached to a horizontal axle around which the unit rotates. The rotational inertia of the unit is 200 kg · m^2, and its radius is 1.00 m. A 30.0-kg child runs and grabs the bottom rung of the ride when it is initially at rest. Because the child can pull herself up to meet the rung at waist height, treat her as a particle located on the rung. (*a*) If the friction between unit and axle is minimal and can be ignored, what is the minimum speed v the child must have when she grabs the bottom rung in order to make the unit rotate about its axle and carry her over the top of the unit? (*b*) Is this a reasonable speed for a child? •••

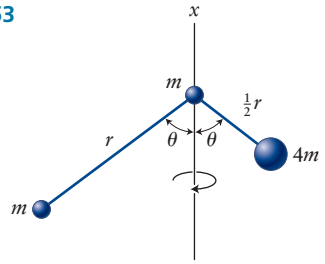


Figure P11.52

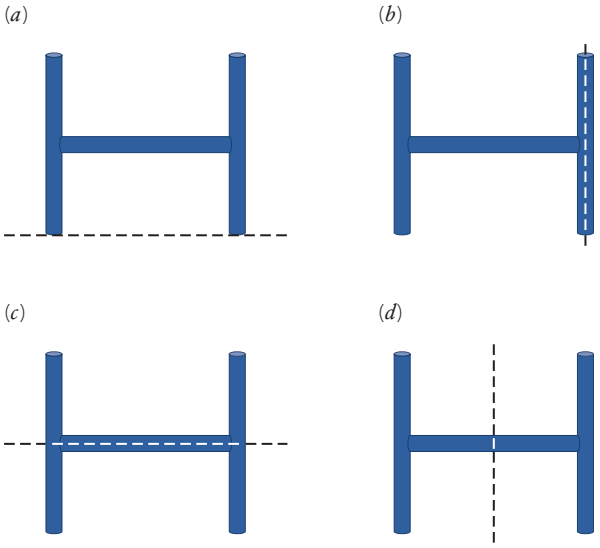
11.6 Rotational inertia of extended objects



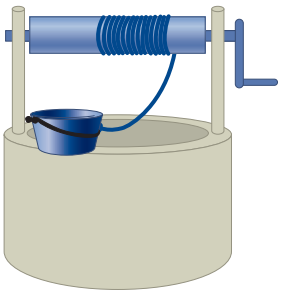
53. What is the rotational inertia about the x axis of the rigid object in Figure P11.53? (Treat the balls as particles.) •

Figure P11.53

54. A cubical wire framework in which each edge is 0.25 m long has a 0.20-kg steel ball at each of its eight corners. What is the rotational inertia of this framework around an axis along one edge? Ignore the inertias of the wires. •
55. What is the formula for the rotational inertia of a thin spherical shell of inertia m and radius R about an axis tangent to any point on its surface? •
56. A deer's leg is very slender near the hoof, with most of the muscle bunched up near the hip joint. How does this work to the deer's advantage? •
57. A 30-kg child running at 1.5 m/s jumps onto a playground merry-go-round that has inertia 190 kg and radius 1.7 m. He is moving tangent to the platform when he jumps, and he lands right on the edge. What is the rotational speed of the merry-go-round and the child if the merry-go-round started from rest? Ignore any friction in the axle about which the platform rotates. ••
58. Earth has an inertia of 5.97×10^{24} kg and a radius of 6.37×10^6 m. (*a*) Calculate its rotational inertia about the rotation axis, assuming uniform density. (*b*) The rotational inertia of Earth about its rotation axis has been measured to be 8.01×10^{37} kg · m^2. What does the difference between this value and the value you calculated in part *a* tell you about the distribution of inertia throughout the planet? ••
59. The rotational inertia of any flat object about an axis perpendicular to the object is equal to the sum of the rotational inertias about two mutually perpendicular axes in the plane of the object, if all three axes pass through a common point. Using this "perpendicular-axis theorem," determine (*a*) the rotational inertia of a uniform hoop of inertia m and radius R about a diameter of the hoop, and (*b*) the rotational inertia of a uniform square sheet of inertia m and side length a about a line drawn from the midpoint of one edge to the midpoint of the opposite edge. ••
60. The structure in Figure P11.60 is made of three identical rods of uniform density. Rank the rotational inertias of the structure, from smallest to largest, about the four rotation axes represented by the dashed lines. ••

Figure P11.60

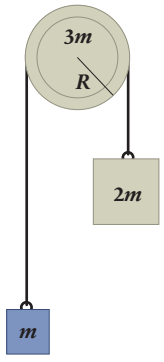
61. Global warming might result in the melting of the polar ice caps. What effect would this melting have on the length of the day? ••



62. A hollow cylinder, a solid cylinder, and a billiard ball are all released at the top of a ramp and roll to the bottom without slipping. (*a*) Rank them, from least to greatest, according to the fraction of the kinetic energy that is rotational as they roll. (*b*) What are the ratios of their speeds when they reach the bottom of the ramp? ••

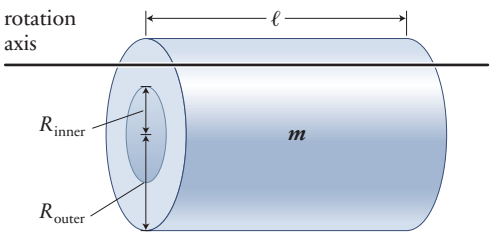
63. Estimate the rotational inertia of a 70-kg athlete about a horizontal axis passing through her waist from left to right. ••

64. A 0.20-kg block and a 0.25-kg block are connected to each other by a string draped over a pulley that is a solid disk of inertia 0.50 kg and radius 0.10 m. When released, the 0.25-kg block is 0.30 m off the ground. What speed does this block have when it hits the ground? ••



65. You accidentally knock a full bucket of water off the side of the well shown in Figure P11.65. The bucket plunges 15 m to the bottom of the well. Attached to the bucket is a light rope that is wrapped around the crank cylinder. How fast is the handle turning when the bucket hits bottom? The inertia of the bucket plus water is 12 kg. The cylinder has a radius of 0.080 m and inertia of 4.0 kg. ••

Figure P11.65



66. A block of inertia m is attached to a block of inertia $2m$ by a light string draped over a uniform disk of inertia $3m$ and radius R that can rotate on a horizontal axle (Figure P11.66). Initially, the block of inertia m is held in place so that the string is taut. When this block is released and so is free to move, what is its speed after it has risen a height h? Ignore friction between disk and axle. ••

Figure P11.66

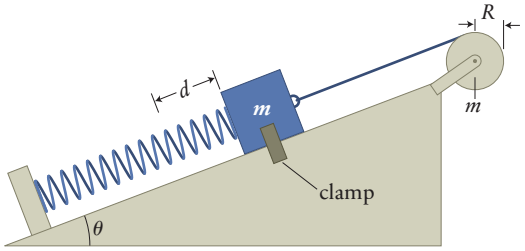
67. A thick-walled cylinder of inertia m has an outer radius R_{outer}, an inner radius $R_{inner} = R_{outer}/2$, and a length ℓ (Figure P11.67). It rotates around an axis attached to its outside along its length. What is its rotational inertia about this axis? ••

Figure P11.67

68. A thin 0.15-kg rectangular sheet has 40-mm short sides and 80-mm long sides. Determine the rotational inertia of the sheet about an axis perpendicular to it and located (*a*) at the center of a long side, (*b*) at the center of a short side, and (*c*) at a corner. ••

69. One type of wagon wheel consists of a 3.0-kg hoop fitted with four 0.90-kg thin rods placed along diameters of the hoop so as to make eight evenly spaced spokes. For a hoop of radius 0.40 m, what is the rotational inertia of the wheel about an axis perpendicular to the plane of the wheel and through the center? ••

70. A thin rod, 0.72 m long, is pivoted such that it hangs vertically from one end. You want to hit the free end of the rod just hard enough to get the rod to swing all the way up and over the pivot. How fast do you have to make the end go? ••



71. Big Ben in London is the most accurate mechanical clock of its size. The 300-kg hour hand is 2.7 m long, and the 100-kg minute hand is 4.2 m long. Calculate the rotational kinetic energy of the two-hand system, treating each hand as if it were a thin rod. ••

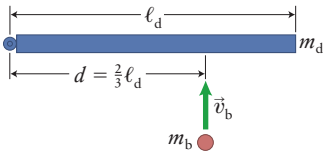
72. Consider an object that has rotational inertia I about some arbitrary axis of rotation. The *radius of gyration* of the object is the distance from this axis where all the object's inertia could be concentrated and still produce the same rotational inertia I about the axis. What is the radius of gyration of (*a*) a solid disk of radius R about an axis perpendicular to the plane of the disk and passing through its center, (*b*) a solid sphere of radius R about an axis through its center, and (*c*) a solid sphere of radius R about an axis tangent to the sphere? •••

73. A thin piece of metal in the shape of a right triangle has inertia m. Its perpendicular sides are of lengths ℓ and 2ℓ. Determine the rotational inertia about an axis that runs (*a*) along side ℓ and (*b*) along side 2ℓ. •••

74. A block of inertia m is attached to a light string wound around a uniform disk also of inertia m (Figure P11.74). The disk has radius R and rotates on a fixed horizontal axle through its center. The opposite side of the block is attached to a spring of force constant k and relaxed length ℓ attached at the bottom of an inclined surface that makes an angle θ with the horizontal. The block is at rest with the spring stretched a distance d from its relaxed length, with the block held in this position by a clamp. When the clamp is loosened so that the block is free to move, the block is pulled down the plane by the spring. What is the speed of the block when the spring is at half of its relaxed length? Ignore friction. •••

Figure P11.74

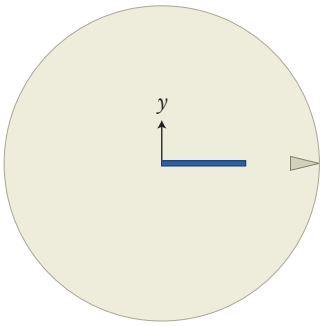
75. A certain baseball bat is a tapered cylinder that increases in diameter from 0.040 m at one end to 0.070 m at the other end and is 0.84 m long. The bat has uniform density and inertia 0.85 kg. What is the rotational inertia of this bat around an axis that passes through its skinny end and is perpendicular to the axis of the bat? •••



Additional Problems

76. In the laboratory, you are trying to put pennies on a rotating platform so that they don't slide off. Your partner tells you, "Pennies on the outside stay on better because $a_c = v^2/r$. For larger r, the centripetal acceleration is less, and so the frictional force has an easier time holding a penny in place out there." Is his reasoning correct? •
77. Solar and lunar eclipses are caused by a fortuitous relationship between the sizes of the Moon and Sun and their distances from Earth. Look up data for the Earth-Moon and Earth-Sun distances and the diameters of the Moon and the Sun. (*a*) Calculate the *angular size* of the Sun's disk as seen by an observer on Earth, where *angular size* is the angle *subtended* by the Sun's disk. (*b*) Calculate the angular size of the Moon's disk. •
78. Show that the centripetal acceleration of an object undergoing circular motion at constant speed can be expressed as

$$a_c = \frac{4\pi^2 r}{T^2},$$



where r is the circle radius and T is the period of the motion. •
79. If you spin a raw egg, stop it momentarily, and then let go, it begins to spin again. You can't do this with a hard-boiled egg. Why? •
80. If you stretch your arm out full length and block the Sun with your thumb, how fast must your thumb move, in millimeters per minute, to track the Sun's motion? ••
81. Out looking for Tarzan, Jane swings on a vine to speed her search. (*a*) During her arc downward, how much work is done on her by the tensile force in the vine? (*b*) At which position along the arc is the force exerted by the vine on Jane greatest? ••
82. The Moon orbits Earth while Earth orbits the Sun, and thus the Moon's motion around the Sun is the combination of those two motions. Is the Moon's motion ever *retrograde* if observed from the Sun, where *retrograde* means that the Moon appears to move in the direction opposite the direction of Earth's motion relative to the distant stars? (You need to look up values for the Earth-Sun distance and the Earth-Moon distance to answer this question.) ••
83. Suppose several particles are in concentric circular orbits under the influence of some centripetal component of force, the magnitude of which depends on distance from the center of the motion. Each particle has a different orbital radius r and a corresponding period T. How does the force depend on r (*a*) if T is proportional to $\sqrt{r}$, (*b*) if T is proportional to $r^{3/2}$, and (*c*) if T is independent of r? ••
84. Approximate the Sun as a uniform sphere of radius 6.96×10^8 m, rotating about its central axis with a period of 25.4 days. If, at the end of its life, the Sun collapses inward to form a uniform dwarf star that is approximately the same size as Earth, what will the period of the dwarf's rotation be? ••
85. An open door of inertia m_d and width ℓ_d is at rest when it is struck by a thrown ball of clay of inertia m_b that is moving at speed v_b at the instant it strikes the door (Figure P11.85). The impact location is a distance $d = \frac{2}{3}\ell_d$ from the rotation axis through the hinges. The clay ball strikes perpendicular to the door face and sticks after it hits. What is the rotational speed ω of the door-ball system? ••

Figure P11.85

86. Your aunt owns an amusement park, and she wants you to add a circular loop to an existing roller-coaster ride. The first hill for the existing roller coaster is 55 m tall, and your aunt wants you to build, right after this hill, the tallest loop possible without having the cars fall out of the track or the passengers fall out of the cars. You think for a minute and realize what the minimum speed at the top of the loop has to be, and this gives you what you need to design the loop. ••• CR
87. The spacecraft in the movie *2001: A Space Odyssey* has a rotating cylinder to create the illusion of gravity, inside of which the crew walks and exercises. While watching this old movie, you realize that the radius of the cylinder is roughly three times a crew member's height. You imagine this cylinder rotating sufficiently rapidly to replicate Earth's gravity, but you worry about the difference between the acceleration at the top of the astronaut's head and the acceleration at her feet. Not wanting light-headed astronauts, you phone NASA with your new design. ••• CR
88. A turntable of radius 0.320 m is fitted with an electromagnet that causes steel objects to stay in place on the table. A triangular mark on the rim shows the rotational position of the table relative to the surroundings (Figure P11.88). The turntable completes one rotation in 0.360 s, and the rotation is counterclockwise in the view shown in the figure. A 0.125-kg steel rod of length 0.160 m is placed on the table so that one end is at the center and the rod is oriented radially outward, as shown in the figure. The electromagnet is switched on, and the turntable is started. After the table reaches its steady-state rotational speed, the electromagnet is switched off at an instant when the rod lies along the positive x axis. Describe the ensuing motion of the rod. •••

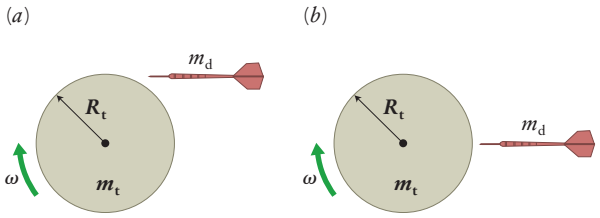


Figure P11.88

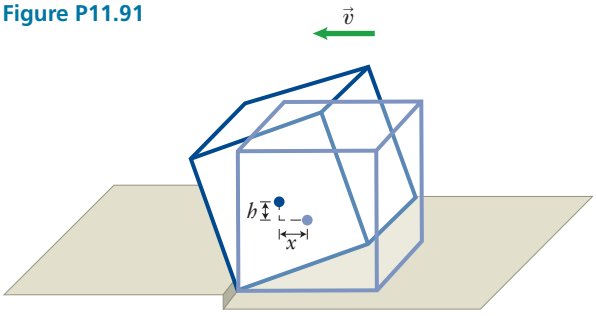
89. You have a toy top that plays music if the rotational speed is at least 1800 rev/min. The way to get this top spinning is to pull on a string wrapped around a spindle of diameter of 6.0 mm. The top has a rotational inertia of about 5.0×10^{-3} kg · m^2. The string is 1.2 m long. To hear the top sing, how hard must you pull on the string? ●●● CR



90. A dart of inertia m_d is fired such that it strikes with speed v_d, embedding its tip in the rim of a target that is a uniform disk of inertia m_t and radius R_t. The target is initially rotating clockwise in the view shown in Figure P11.90, with rotational speed ω about an axis that runs through its center and is perpendicular to its plane. Assume that the dart's inertia is concentrated at its tip. What is the final rotational speed of the target if the dart strikes (*a*) tangent to the target rim as in Figure P11.90*a* and (*b*) normal to the rim as in Figure P11.90*b*? ●●●

Figure P11.90

91. A smooth-faced cube of inertia m and side length d sliding along a highly polished floor at speed v strikes a door threshold, and the collision makes the cube tilt as shown in Figure P11.91. As the cube tips over, its center of mass is located at a variable horizontal distance x; $x = 0$ when the cube strikes the threshold. What is the rotational speed of the cube as a function of x? The rotational inertia of a cube about one edge is $\frac{2}{3}md^2$. [Hint: Call the vertical distance traveled by the center of mass h.] ●●●

QUANTITATIVE TOOLS

12.5 Conservation of angular momentum
12.6 Rolling motion
12.7 Torque and energy
12.8 The vector product

Having described the basic principles of rotational motion, we now turn our attention to the cause of changes in this motion. Continuing to exploit the analogy between translational and rotational motion, we introduce a rotational analog of force called *torque*. A torque can cause an object's angular momentum to change, in the same way that a force can cause an object's momentum to change. We also study how to describe rotations that take place about an axis that is not fixed. To complete our description of rotations, we examine rotations in more than one dimension.

12.1 Torque and angular momentum

In the preceding chapter we studied how objects can be made to rotate. As I mentioned in Section 11.5, tangential components of forces cause the angular momentum of an object to change (Figure 11.31). If you exert a force on the edge of a stationary wheel in a direction tangential to the rim, as illustrated in **Figure 12.1a**, the wheel starts to rotate. To twist the cap off a jar, you exert a tangential force at the edge of the cap, as in Figure 12.1*b*.

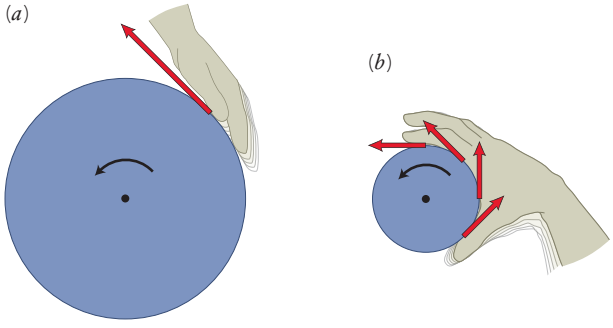
When you exert a force on an object to set it in translational motion, only the magnitude and direction of that force play a role: The object accelerates in the direction of the force, and the greater your force, the greater the acceleration. When you exert a force on an object to twist or rotate the object, not only the magnitude and the direction of the force but also the point at which you exert it determine how effective that force is in rotating the object. For example, if you push on a seesaw to lift a child seated on the opposite end, as illustrated in **Figure 12.2**, it is best to push as far as possible from the pivot of the seesaw and to push in a direction perpendicular to the seesaw. If you push very close to the pivot or if you push in a direction not perpendicular to the seesaw, it is more difficult to rotate the seesaw about its pivot. For a force of a given magnitude, the ability to rotate the seesaw is greatest when the force is exerted as indicated in Figure 12.2*a*.

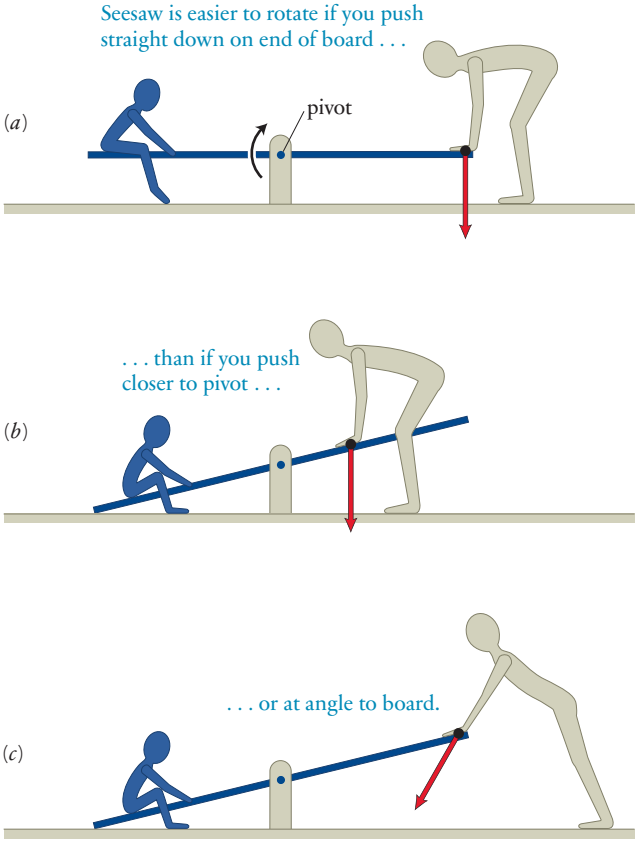
The reason that the ability of a force to rotate objects depends on the point of application is most easily understood in terms of energy and work. Suppose you raise the child of Figure 12.2 by exerting a force $\vec{F}$ straight down on the opposite end of the seesaw, as in **Figure 12.3*a*** on the next page. Raising the child a vertical distance Δy means increasing the gravitational potential energy of the Earth-child system by an amount $mg\,\Delta y$, where m is the child's inertia. This increase in potential energy is due to work done by you on the system. As you raise the child a distance Δy, your end of the seesaw goes down an equal amount. The work done by you on the system is equal to the magnitude of the force times the force displacement, or $F\,\Delta y_F$. If the child begins and ends at rest, so that there is no change in kinetic energy, the work done by you on the system must equal the change in potential energy of the Earth-child system: $mg\,\Delta y = F\,\Delta y_F$. So we see that to lift the child by pushing on the opposite end of the seesaw, the magnitude of the force $\vec{F}$ must be equal to the magnitude mg of the force of gravity on the child.

Suppose, however, you had pushed not on the far end of the seesaw but rather halfway between the pivot and the end. As Figure 12.3*b* shows, that point of the seesaw moves down only half the original force displacement, and so to do the same amount of work, the force you must exert is twice as great as before. The closer to the pivot you push, the greater the force required to raise the child.

We can use the same line of reasoning to understand why the force is most effective when it is oriented perpendicular to the seesaw. If the exerted force points in any other direction, we can decompose it into components

Figure 12.1 To (*a*) make a wheel rotate and (*b*) twist a cap off a jar, you must exert a force tangential to their rims.





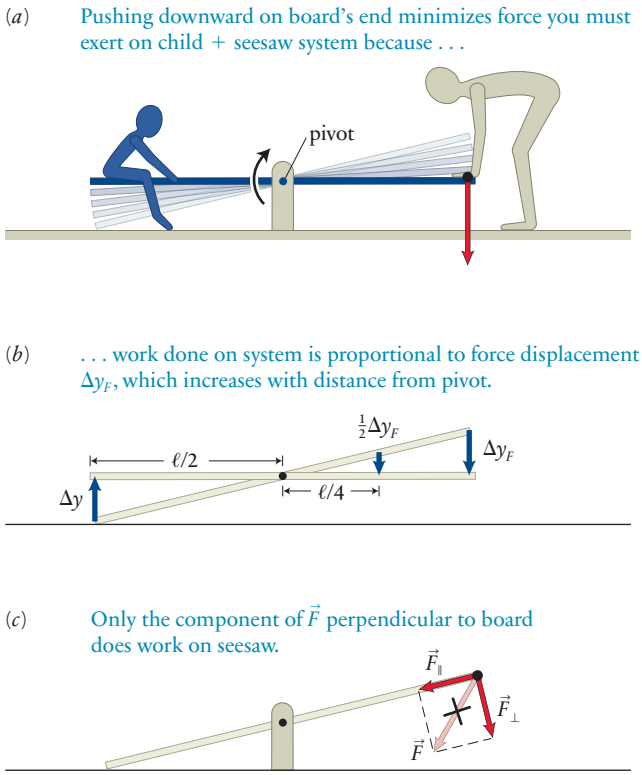


Figure 12.2 Easier and harder ways to rotate a seesaw.

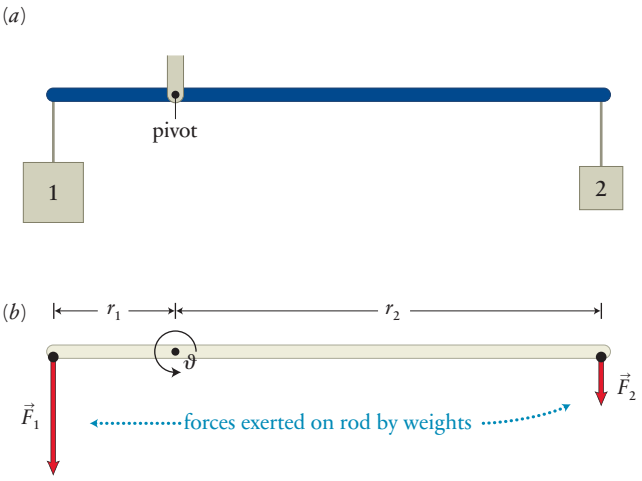
CONCEPTS

Figure 12.3 The reason you can rotate the seesaw most easily by pushing downward on the end of the board.

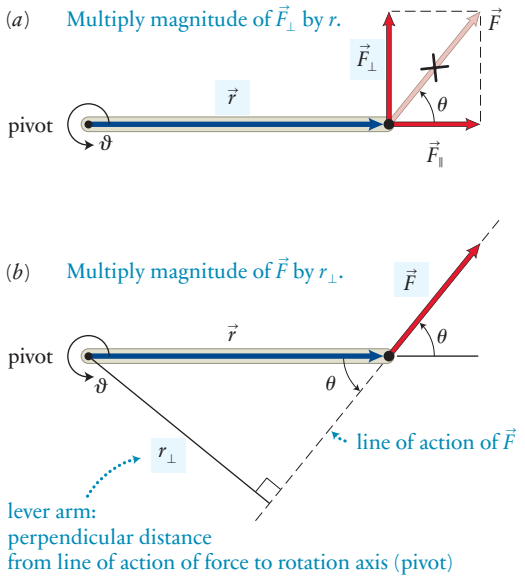


parallel and perpendicular to the seesaw (Figure 12.3*c*). The component parallel to the seesaw merely pushes the seesaw against the pivot and doesn't contribute to any rotational displacement of the seesaw: In the extreme case that the force is directed entirely along the seesaw, nothing happens. So it is only the component perpendicular to the seesaw, $\vec{F}_\perp$, that causes the seesaw to rotate.

To find out more accurately what determines the turning ability of a force, consider the rod in **Figure 12.4**. The rod is suspended by a pivot attached at a point that is off-center, and the rod is free to rotate about that point. Two objects of unequal inertias m_1 and m_2 are suspended on either end of the rod, keeping the rod in balance so that it is at rest. For simplicity we assume that the inertia of the rod is negligible compared to m_1 and m_2. Before reading on, complete the following checkpoint.

12.1 (*a*) Draw a free-body diagram for the rod of Figure 12.4. Let the inertia of the rod be negligible compared to m_1 and m_2. (*b*) Would the free-body diagram change if you slide object 2 to the left? (*c*) Experiments show that when $m_1 = 2m_2$ the rod is balanced for $r_2 = 2r_1$. How is the ratio r_1/r_2 related to the ratio m_1/m_2? (*d*) What would happen if you remove object 1 from the rod? (*e*) What would happen if you double the inertia of object 1? (*f*) What would happen if you carefully place a penny on top of object 1? Let the inertia of the two objects be significantly larger than that of the penny. (*g*) Is there a difference between what would happen in parts *e* and *f*?

Figure 12.4 Unequal weights balance a rod that is suspended off-center.



The forces exerted by the two objects in Figure 12.4 each have the ability to rotate the rod—object 1 tends to rotate the rod in a counterclockwise direction, object 2 in a clockwise direction. This ability of a force to rotate an object about an axis is called the **torque** about that axis. Torque is the rotational analog of force: Forces cause (translational) acceleration; torques cause rotational acceleration about an axis. The rod in Figure 12.4 is balanced because the torques caused by the two forces—their ability to rotate the rod—are equal in magnitude, but the rotations they tend to cause are in opposite directions, and so they sum to zero.

Note that the magnitudes of the two forces that cause these equal torques in opposite directions are not themselves equal: $F_1 = m_1 g$ and $F_2 = m_2 g$, with $m_2 \neq m_1$. From experiment we know, however, that the rod is balanced when $r_1 F_1 = r_2 F_2$. This suggests that the torque caused by each force is $r_\perp F$, the product of the magnitude of that force and the lever arm distance of the force relative to the axis of rotation (the perpendicular distance between the line of action of the force and the pivot; see Section 11.5). The line of action of the upward force exerted by the pivot on the rod (see Checkpoint 12.1) goes through the axis of rotation. Consequently, the corresponding lever arm distance is zero, and so this force does not cause any torque about the pivot.

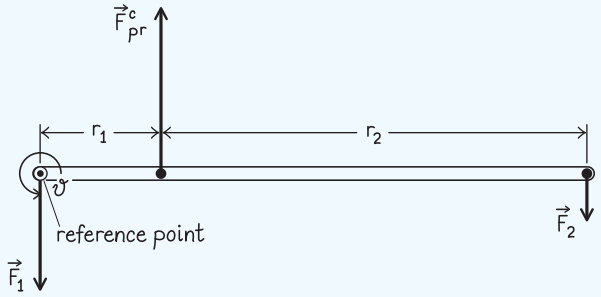
In Figure 12.4, the forces exerted on the rod are perpendicular to it. **Figure 12.5** shows two equivalent ways to determine the torque caused by a force that is not perpendicular to the radial line from the pivot to the point of application of the force. One way is to decompose the force into components parallel and perpendicular to this axis (Figure 12.5*a*). Only the perpendicular component causes the lever to rotate; the parallel component simply pulls on the pivot. The torque caused by $\vec{F}$ is thus $rF_\perp = r(F \sin\theta)$, where r is the length of the vector pointing from the axis of rotation to the point of application of the force. Note that we can also write

CONCEPTS

Figure 12.5 Two ways to determine the torque caused by a force exerted on a lever at an angle θ.

this torque as $(r \sin\theta)F$, which is precisely $r_\perp F$, as we surmised. Figure 12.5*b* shows how to determine $r_\perp$: It is the perpendicular distance between the line of action of the force and the axis of rotation. So, the torque caused by a force exerted on an object is the product of the magnitude of the force and its lever arm distance. It can be written equivalently as $rF_\perp$ and as $r_\perp F$.

Like other rotational quantities, torque carries a sign that depends on the choice of direction for increasing ϑ. In Figure 12.4, for example, the torque caused by $\vec{F}_1$ about the pivot tends to rotate the rod in the direction of increasing ϑ and so is positive; the torque caused by $\vec{F}_2$ is negative. The sum of the two torques about the pivot is then $r_1F_1 + (-r_2F_2)$. As we've seen, the two torques are equal in magnitude when the rod is balanced, and so the sum of the torques is zero. When the sum of the torques is not zero, the rod's rotational acceleration is nonzero, and so its rotational velocity and angular momentum change.



In the situations depicted in Figures 12.4 and 12.5 we used the pivot to calculate the lever arm distances. This is a natural choice because that is the point about which the object under consideration is free to rotate. However, torques also play a role for stationary objects that are suspended or supported at several different points and that are not free to rotate—for example, a plank or bridge supported at either end. To determine what reference point to use in such cases, complete the following exercise.

EXERCISE 12.1 Reference point

Consider again the rod in Figure 12.4. Calculate the sum of the torques about the left end of the rod.

SOLUTION I begin by making a sketch of the rod and the three forces exerted on it, showing their points of application on the rod (**Figure 12.6**).

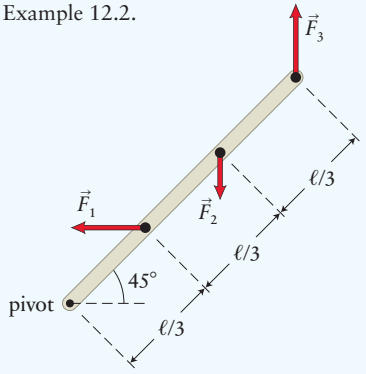
Figure 12.6

The lever arm distances must now be determined relative to the left end of the rod. The lever arm distance of force $\vec{F}_1$ to this point is zero, and so the torque caused by that force about the left end of the rod is zero. If I choose counterclockwise as the positive direction of rotation, $\vec{F}_2$ causes a negative torque about the left end of the rod; the force $\vec{F}^c_{pr}$ exerted by the pivot causes a positive torque about the left end of the rod. The lever arm distance of $\vec{F}_2$ about the left end of the rod is $r_1 + r_2$; that of $\vec{F}^c_{pr}$ is r_1. Because the rod is at rest, the magnitude of the force exerted by the pivot is equal to the sum of the forces $\vec{F}_1$ and $\vec{F}_2$. Taking into account the signs of the torques, we find that the sum of the torques about the left end of the rod is $r_1(F_1 + F_2) - (r_1 + r_2)F_2 = r_1F_1 - r_2F_2$. This is the same result we obtained for the torques about the pivot, and so the sum of the torques about the left end is zero. ✔

Exercise 12.1 shows that the sum of the torques about the left end of the rod is zero, just like the sum of the torques about the pivot. You can repeat the calculation for the torques about the right end of the rod or any other point, and each time you will find that the sum of the torques is zero. The reason is that the rod is not rotating about any point, and so the sum of the torques must be zero about any point. In general we can say:

For a stationary object, the sum of the torques is zero.

For a stationary object we can choose any reference point we like to calculate torques. It pays to choose a reference point that simplifies the calculation. As you have seen, we do not need to consider any force that is exerted at the reference point. So, by putting the reference point at the point of application of a force, we can eliminate that force from the calculation.



12.2 In the situation depicted in Figure 12.2*a*, you must continue to exert a force on the seesaw to keep the child off the ground. The force you exert causes a torque on the seesaw, and yet the seesaw's rotational acceleration is zero. How can this be if torques cause objects to accelerate rotationally?

CONCEPTS

EXAMPLE 12.2 Torques on lever

Three forces are exerted on the lever of Figure 12.7. Forces $\vec{F}_1$ and $\vec{F}_3$ are equal in magnitude, and the magnitude of $\vec{F}_2$ is half as great. Force $\vec{F}_1$ is horizontal, $\vec{F}_2$ and $\vec{F}_3$ are vertical, and the lever makes an angle of 45° with the horizontal. Do these forces cause the lever to rotate about the pivot? If so, in which direction?

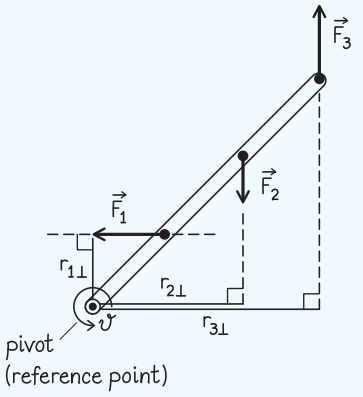


Figure 12.7 Example 12.2.

❶ **GETTING STARTED** I begin by arbitrarily choosing counterclockwise as the direction of increasing ϑ. With that choice of ϑ, $\vec{F}_1$ and $\vec{F}_3$ cause positive torques about the pivot, while $\vec{F}_2$ causes a negative torque. To answer the question, I need to determine the magnitude and sign of the sum of these three torques about the pivot.

❷ **DEVISE PLAN** The forces are not perpendicular to the long axis of the lever, and so I need to follow one of the two procedures shown in Figure 12.5 to determine the torques about the pivot. I arbitrarily choose to determine the lever arm distances. To determine these distances relative to the pivot, I make a sketch showing the forces and the perpendicular distance from the pivot to the line of action of each force (Figure 12.8). I can then get the magnitude of each torque by multiplying each force magnitude by the corresponding lever arm distance. Knowing the sign and magnitude of each torque, I can determine the combined effect of the three torques.

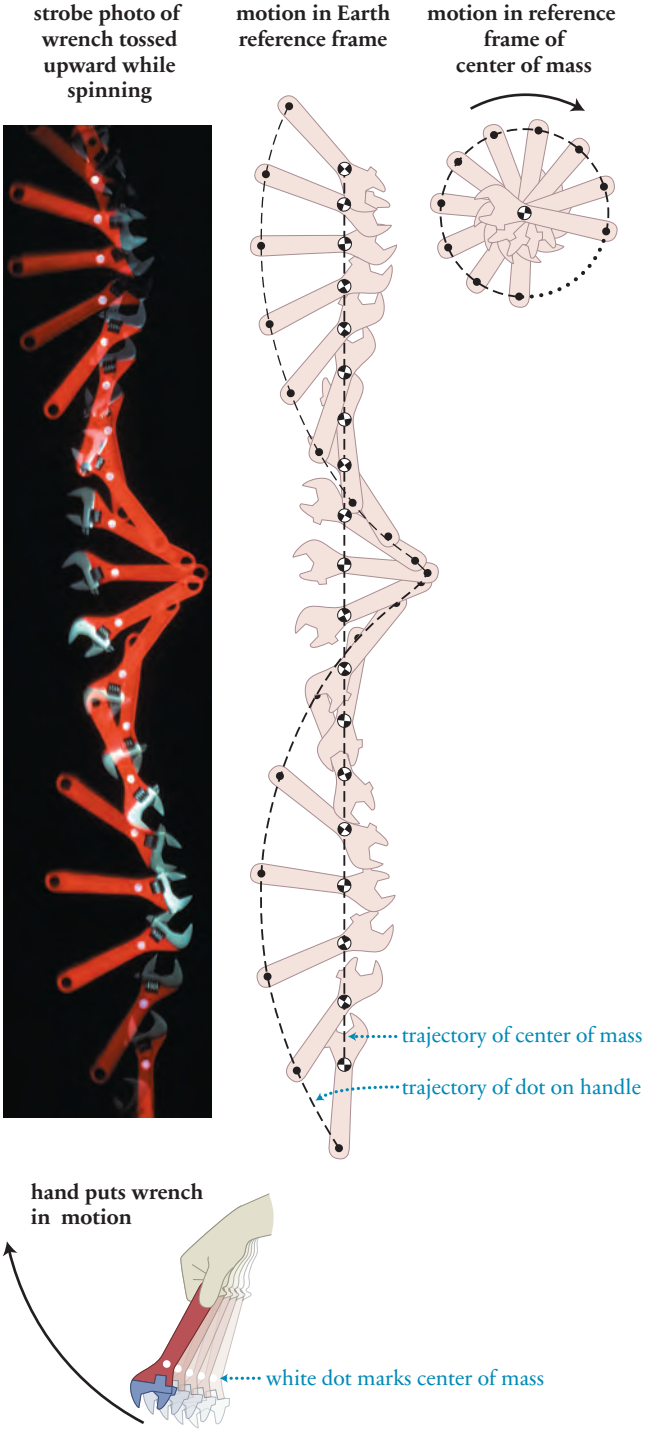
Figure 12.8

❸ **EXECUTE PLAN** I know that $F_1 = 2F_2$. My sketch tells me that $r_{1\perp} = (\ell/3)\sin 45°$ and $r_{2\perp} = (2\ell/3)\cos 45°$, and so $r_{1\perp} = \frac{1}{2}r_{2\perp}$ because $\sin 45° = \cos 45°$. Therefore the torques caused by these two forces about the pivot are equal in magnitude: $r_{1\perp}F_1 = \left(\frac{1}{2}r_{2\perp}\right)(2F_2) = r_{2\perp}F_2$. Because the two torques carry opposite signs, their sum is thus zero and their effects cancel. This means that the torque caused by $\vec{F}_3$ determines whether or not the lever rotates and, if so, in which direction. Because this torque is nonzero and counterclockwise, the lever rotates in a counterclockwise direction. ✔

❹ **EVALUATE RESULT** Looking at Figure 12.7, I see that the two larger forces ($\vec{F}_1$ and $\vec{F}_3$) cause counterclockwise torques about the pivot, and only the smaller force $\vec{F}_2$ causes a clockwise torque. Thus it makes sense that the lever rotates in the counterclockwise direction.

12.3 (*a*) Without changing the magnitude of any of the forces in Example 12.2, how must you adjust the direction of $\vec{F}_3$ to prevent the lever from rotating? (*b*) If, instead of adjusting the direction of $\vec{F}_3$, you adjust the magnitude of $\vec{F}_2$, by what factor must you change it?

12.2 Free rotation



So far we have considered only rotations about a *fixed axis*, one that constrains the object to rotate about that axis and prevents it from moving away from the axis. Examples of such physical axes are axles, pivots, fulcrums, joints, and hinges. Objects don't need a physical axis to rotate, however. Put a pencil on your desk and flick one end with your finger. The pencil will move away from your hand while executing a rotating motion. A Frisbee flies through the air spinning about its center—without a physical axis through it. The rotation of objects that are not constrained by a physical axis or by other external constraints is called **free rotation.** About what point or axis do freely rotating objects like the pencil and the Frisbee rotate? Can an object be made to rotate about any point if nothing constrains it to rotate about some particular point?

Figure 12.9 shows the motion of a wrench after being launched as shown at the bottom of the figure. Hold the wrench by the end of the handle and sharply flip your wrist clockwise while launching the wrench upward. As the wrench moves upward, it executes a free rotation. The strobe photograph in Figure 12.9 allows us to analyze this motion. As you can see, the trajectory of the end of the handle is neither linear nor circular. Note, however, that the motion of the white dot on the wrench is remarkably simple: The dot moves straight up. What point does this white dot correspond to?

In Section 8.12, I showed that when external forces are exerted on the particles in a many-particle system, the system's center of mass moves as though all the particles in the system were concentrated at the center of mass and all external forces were exerted at that point. This statement is a direct result of conservation of momentum and of the definition of center of mass. The wrench, which consists of many atoms, is a many-particle system, and as it moves upward, Earth exerts a downward gravitational force on each atom in the wrench. The result we obtained in Section 8.12 thus states that the center of mass of the wrench should

CONCEPTS

Figure 12.9 Motion of a wrench that is launched upward so that it rotates.

move upward as if it were a particle moving under the influence of gravity. Indeed, if you closely examine the spacing of the dots in Figure 12.9, you can see that the spacing decreases. This tells you that the dot slows down as it moves upward. Quantitative analysis of the motion of the dot shows that the magnitude of the dot's downward acceleration is exactly g—that is, equal to that of an object launched without rotation.

So, the white dot on the wrench is the center of mass of the wrench, and other points on the wrench rotate around it. The center of mass is in translational motion at constant acceleration and thus cannot be rotating. This is true in general:

Objects that are made to rotate without external constraints always rotate about the center of mass.

This statement shows how remarkably powerful the concept of center of mass is. It allows us to break down the complex motion of the freely rotating wrench into two separate parts: the translational motion of the center of mass and a rotational motion of the wrench about the center of mass. This separation greatly simplifies the analysis of the motion because we can treat each part separately with the tools we have already developed.

12.4 As the wrench in Figure 12.9 moves upward, the upward translational motion of its center of mass slows down. Does the rotation about the center of mass also slow down? Which way does the wrench rotate when it falls back down after reaching its highest position?

12.3 Extended free-body diagrams

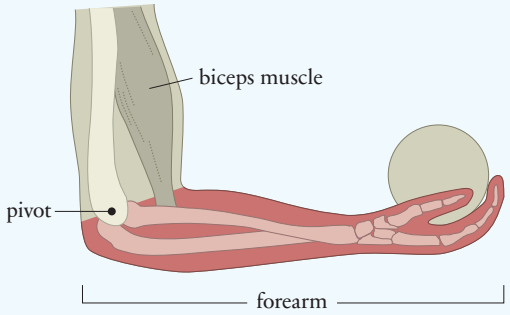
In Chapter 8 we developed a procedure for making free-body diagrams. These diagrams help us determine the *vector sum of the forces exerted on* an object, which, along with initial position and initial velocity, determines the motion of the object's center of mass. Free-body diagrams, however, do not provide any insight into the rotation of an object. For instance, if you push against the right end of a pencil that lies on a table, the pencil moves and rotates counterclockwise; pushing on the left end makes it rotate clockwise. If you push at the center of the pencil, you can even make it move without rotation. The free-body diagram for the pencil, however, is the same regardless of where you push.

To account for the rotation of an object, we must determine what torques are caused by the forces exerted on that object, and so we must know the lever arm distance of each force—information that is not contained in the free-body diagram because all forces are drawn with their tail at the center of the object. We must therefore develop a new kind of diagram that shows not only the forces exerted on an object but also the location of the point of application of each force relative to some chosen reference point. Such a diagram is called an **extended free-body diagram.** The procedure for making these diagrams is described in the Procedure box on page 394.

Drawing an extended free-body diagram and choosing a reference point help you determine the lever arm distances to that point so you can calculate the magnitude and direction of the torques about that point.

CONCEPTS

PROCEDURE: Extended free-body diagrams



1. Begin by making a standard free-body diagram for the object of interest (the *system*) to determine what forces are exerted on it. Determine the direction of the acceleration of the center of mass of the object, and draw an arrow to represent this acceleration.
2. Draw a cross section of the object in the plane of rotation (that is, a plane perpendicular to the rotation axis) or, if the object is stationary, in the plane in which the forces of interest lie.
3. Choose a reference point. If the object is rotating about a hinge, pivot, or axle, choose that point. If the object is rotating freely, choose the center of mass. If the object is stationary, you can choose any reference point. Because forces exerted at the reference point cause no torque, it is most convenient to choose the point where the largest number of forces is exerted or where an unknown force is exerted. Mark the location of your reference point and choose a positive direction of rotation. Indicate the reference point in your diagram by the symbol ⊙.
4. Draw vectors to represent the forces that are exerted on the object and that lie in the plane of the drawing. Place the tail of each force vector at the point where the force is exerted on the object. Place the tail of the gravitational force exerted by Earth on the object at the object's center of mass.* Label each force.
5. Indicate the object's rotational acceleration in the diagram (for example, if the object accelerates in the positive ϑ direction, write $\alpha_\vartheta > 0$ near the rotation axis). If the rotational acceleration is zero, write $\alpha_\vartheta = 0$.

*Is the gravitational force really exerted at the center of mass? Suppose the gravitational force exerted by Earth were exerted at some other point. The force would then cause a permanent torque about the center of mass, and any object dropped from rest would begin spinning, which is not true.

EXERCISE 12.3 Holding a ball

You hold a ball in the palm of your hand, as shown in **Figure 12.10**. The bones in your forearm act like a horizontal lever pivoted at the elbow. The bones are held up by the biceps muscle, which makes an angle of about 15° with the vertical. Draw an extended free-body diagram for your forearm.

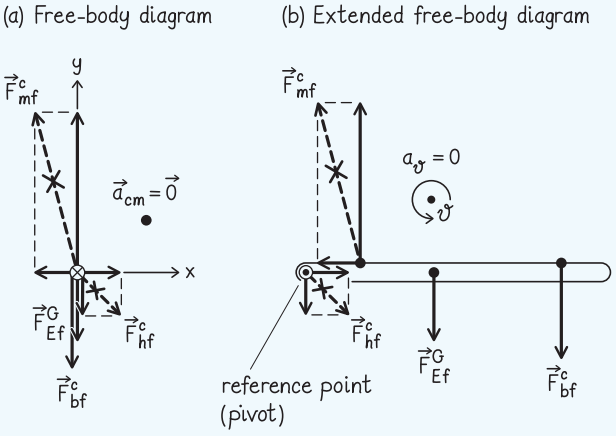


Figure 12.10 Exercise 12.3.

SOLUTION I begin by making a standard free-body diagram for the forearm, which is in contact with the upper-arm bone (the *humerus*), the biceps muscle, and the ball, all of which exert contact forces on it. In addition, there is the gravitational force $\vec{F}^G_{Ef}$ to show in my diagram. I know the direction of $\vec{F}^c_{bf}$ (down), $\vec{F}^c_{mf}$ (up and to the left), and $\vec{F}^G_{Ef}$ (down) but not the direction of $\vec{F}^c_{hf}$.

How do I come up with a reasonable direction for $\vec{F}^c_{hf}$ in my diagram? I know that the forearm is at rest, which means its linear acceleration is zero, and so the vector sum of the forces exerted on the forearm must be zero. This means that the component of $\vec{F}^c_{hf}$ parallel to the forearm must be equal in magnitude to the parallel component of $\vec{F}^c_{mf}$ but pointing in the opposite direction. Because I cannot determine off-hand what the perpendicular component of $\vec{F}^c_{hf}$ is, I draw a force vector pointing down at some arbitrary angle and adjust its length so that the two parallel components are equal in length. Finally I adjust all the perpendicular components so that their sum is zero. This gives me the free-body diagram shown in **Figure 12.11a**. Because the arm is at rest, I write $\vec{a}_{cm} = \vec{0}$ next to the diagram. The zero acceleration tells me that the vector sum of the forces exerted on the arm is zero.

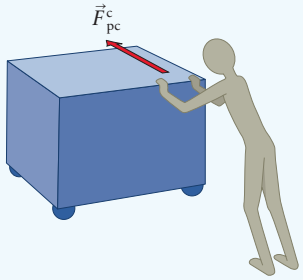
Figure 12.11

Next I turn to the extended free-body diagram. I represent the forearm as a horizontal rod, with the pivot on the left, as shown in Figure 12.11*b*. Because the forearm is at rest, I can choose any point as the reference point. Because I know the least about $\vec{F}^c_{hf}$, however, it makes sense to choose my reference point at the pivot where that force is exerted. I choose the positive direction of rotation to be counterclockwise and write $\alpha_\vartheta = 0$ next to it because the forearm is not rotating.

Finally I draw the same forces as in the free-body diagram, placing their tails at their points of application. The result is shown in Figure 12.11*b*. The perpendicular component of $\vec{F}^c_{mf}$ causes a positive torque, $\vec{F}^G_{Ef}$ and $\vec{F}^c_{bf}$ cause negative torques, and $\vec{F}^c_{hf}$ causes no torque because its lever arm distance is zero. ✔

You will work out a quantitative solution to this problem in Checkpoint 12.8.

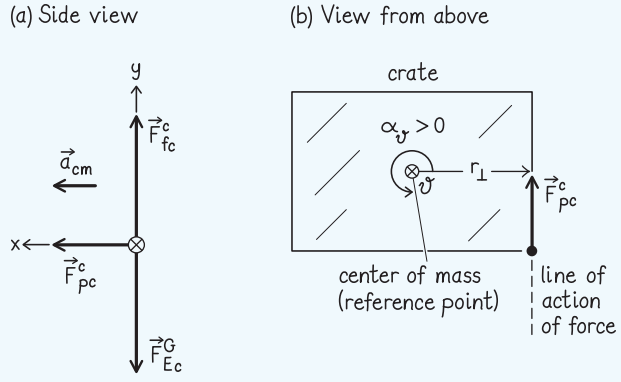
CONCEPTS



12.5 (*a*) If the biceps muscle in Figure 12.10 were attached farther out toward the wrist, would the torque generated by the muscle about the pivot get greater, get smaller, or stay the same? (*b*) As the hand is raised above the level of the elbow, so that the forearm makes an angle of 15° with the horizontal, does the arm's capacity to lift objects increase, decrease, or stay the same?

As you may have noticed, the information in the extended free-body diagram overlaps with that in the free-body diagram. Is it then necessary to draw both? I strongly recommend doing so until you have gained some practice. The standard free-body diagram helps you find the vector sum of the forces exerted on the object, which determines the object's translational motion. In the extended free-body diagram, it is more cumbersome to decompose vectors and add components, and so it is easier to make errors. The extended free-body diagram, however, is necessary to determine the torques caused by the forces that are exerted on the object. The next exercise helps clarify the purpose of each diagram.

EXERCISE 12.4 Pushing a large crate



You are moving a large crate mounted on swivel wheels, exerting an off-center force $\vec{F}^{c}_{pc}$ as shown in **Figure 12.12**. Draw an extended free-body diagram for the crate. You can ignore any friction in the wheels.

Figure 12.12 Exercise 12.4.

SOLUTION The forces exerted on the crate are a downward force of gravity, an upward contact force exerted by the floor, and your horizontal push. I therefore draw the free-body diagram shown in **Figure 12.13*a***.

Figure 12.13

The free-body diagram shows that the vector sum of the forces exerted on the crate is nonzero. From this information I conclude that the push causes the center of mass of the crate to accelerate in the direction of the push. I therefore draw an arrow next to the free-body diagram to indicate the direction of this center-of-mass acceleration.

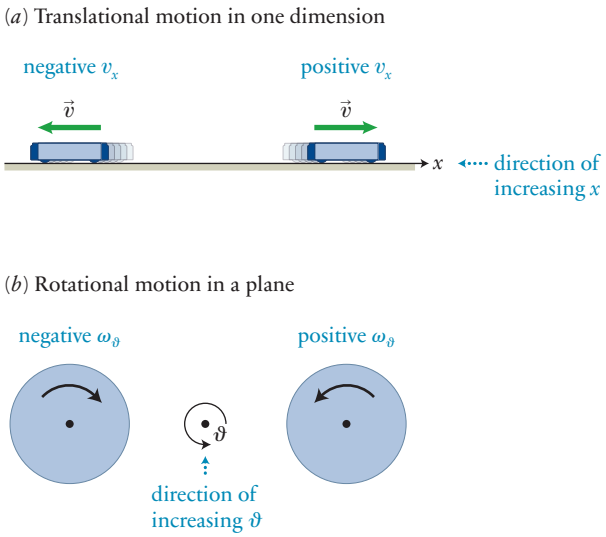
The crate is not constrained to rotate about a fixed axis. The floor and the wheels it is resting on, however, do constrain it to rotate in the horizontal plane. In addition to accelerating the center of mass of the crate, the off-center push therefore causes the crate to rotate about a vertical axis through the center of mass. Because the rotation is in the horizontal plane, I draw an outline of the crate as seen from above for the extended free-body diagram.

The crate is not constrained to rotate about any fixed axis in the plane I have drawn, so the center of mass is the reference point I must use. I assume the crate to be uniform, so its center of mass is at the center. I mark the reference point in my diagram and choose counterclockwise as the direction of positive rotation.

The only force that lies in this plane is $\vec{F}^{c}_{pc}$, so the extended free-body diagram contains just one force (Figure 12.11*b*). The lever arm distance of $\vec{F}^{c}_{pc}$ is the distance between its line of action and the center of mass of the crate. From the diagram, I thus conclude that $\vec{F}^{c}_{pc}$ causes a counterclockwise torque. This torque causes the crate to rotate counterclockwise, and I write $a_\vartheta > 0$ next to the diagram to indicate that the rotational acceleration of the crate is positive. ✔

12.6 Suppose the force $\vec{F}^{c}_{pc}$ in Exercise 12.4 gives the center of mass of the crate an acceleration $\vec{a}_{cm}$. Would this acceleration be greater, smaller, or the same if the force were exerted exactly at the center of the crate?

12.4 The vectorial nature of rotation



So far we've treated all rotational quantities as if they were scalars. There are two reasons a scalar treatment of rotational quantities cannot be complete, however: Rotations have direction, and the rotation axis has a definite orientation in space. For rotations that lie in a single plane, an algebraic sign is sufficient to indicate the direction of rotation in the same way that an algebraic sign indicates direction in one-dimensional translational motion, as shown in **Figure 12.14** on the next page.

For rotations in three dimensions, the algebraic sign alone is not sufficient to determine the direction of rotation. Consider, for example, the two spinning disks in **Figure 12.15** on the next page. If you view them from the angle shown in Figure 12.15*a*, you could claim that the disk A spins counterclockwise and disk B clockwise. Seen from below, as in Figure 12.15*b*, however, disk A spins clockwise and the rotation of disk B, now seen sideways, is neither clockwise nor counterclockwise. So, in three dimensions the terms *clockwise* and *counterclockwise* are insufficient to specify the direction of a rotation, just as *positive* and *negative* are not enough to specify a displacement vector in more than one dimension.

Can a rotation be characterized by a vector? The vectors $\vec{r}$, $\vec{v}$, and $\vec{a}$ of an object in circular motion at

CONCEPTS

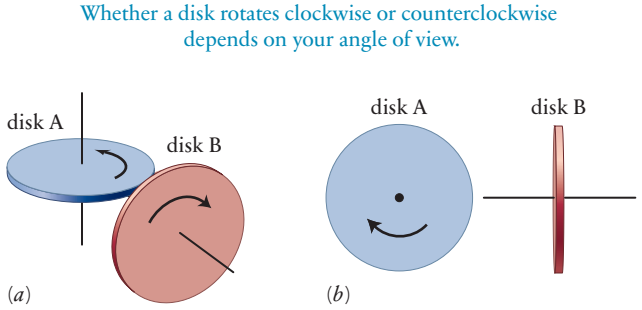
Figure 12.14 For both translation in one dimension and rotation in a plane, the two possible directions of motion can be distinguished by their algebraic sign.

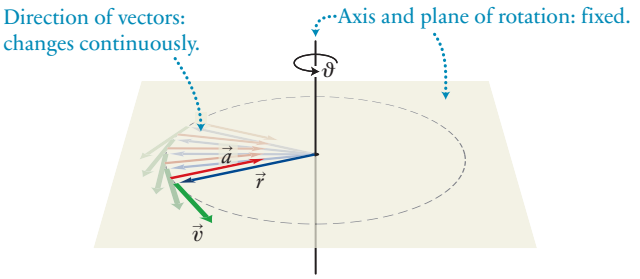
constant speed all lie in the plane of the trajectory, as shown in **Figure 12.16*a***. Their directions change every instant, and because all directions in the plane are equivalent, it makes no sense to associate a vector in this plane with the rotation. How would we agree on which direction to pick? The direction of the rotation axis, a direction in which the vectors $\vec{r}$, $\vec{v}$, and $\vec{a}$ never point, is the only direction associated with the rotation that remains fixed. We can specify the orientation of the rotation axis by a vector. Given that vector, you know the orientation of the plane in which the rotation takes place.

If we use a vector to specify the orientation of the rotation axis in space, we can use the two possible directions along this axis to represent the two possible directions of rotation about the axis. The convention for associating a vector along the rotation axis with the direction of rotation is illustrated in Figure 12.16*b* and is called the **right-hand rule:**

> **When you curl the fingers of your right hand along the direction of rotation, your thumb points in the direction of the vector that specifies the direction of rotation.**

Figure 12.15 For rotations in three dimensions, it is no longer possible to specify the direction of rotation unambiguously by algebraic sign or by the terms *clockwise* and *counterclockwise*.





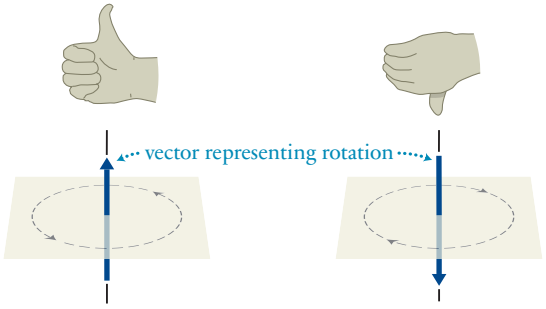


Figure 12.16 Right-hand rule and directions associated with rotations.

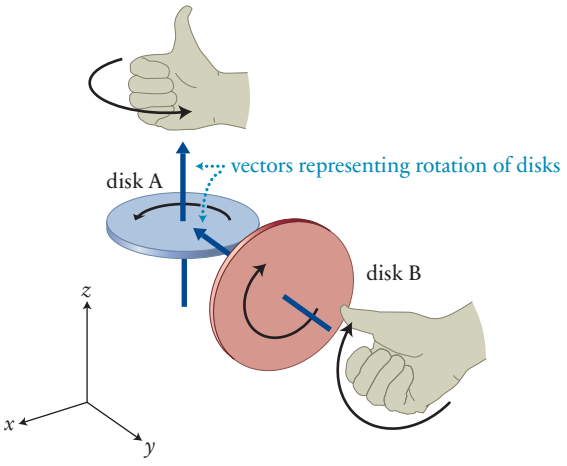
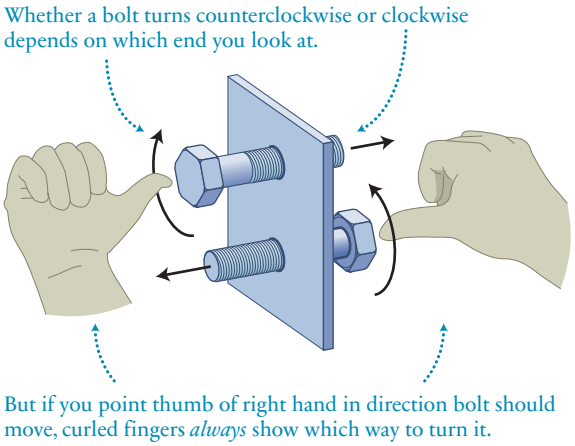
(*a*) Vectors $\vec{r}$, $\vec{v}$, and $\vec{a}$ cannot be associated with a direction of rotation.



(*b*) The right-hand rule connects direction of rotation about an axis with a direction along the rotation axis.

Right-hand rule: Curl fingers of right hand in direction of rotation; thumb will point in direction of vector representing rotation.



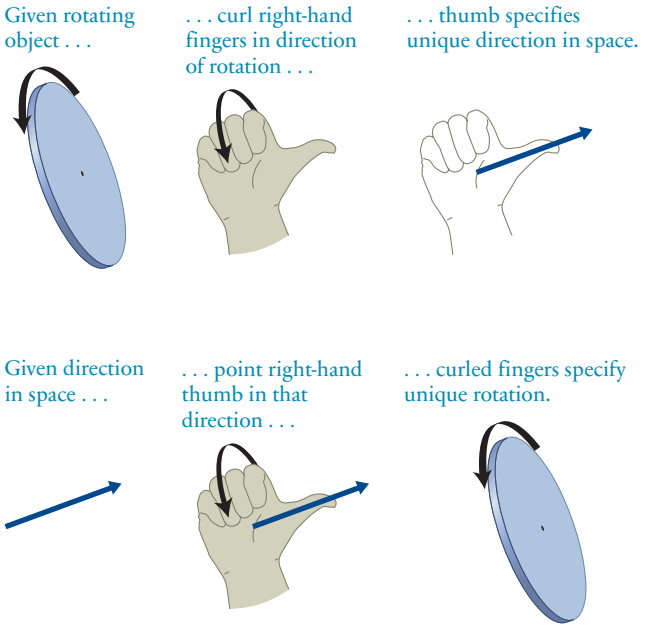
Armed with this rule, you can now specify the direction of any rotation and the orientation of the axis about which that rotation takes place with a vector and avoid the ambiguity of terms like *clockwise* and *counterclockwise*. For example, for the two disks in Figure 12.15*a* the right-hand rule yields the directions given by the two blue vectors in **Figure 12.17**. The advantage of the vectors is that we can specify them by giving their x, y, and z components. The vector representing

Figure 12.17 The right-hand rule applied to the spinning disks of Figure 12.15.

CONCEPTS

Figure 12.18 The right-hand rule tells you how to tighten a bolt regardless of your position relative to the bolt.

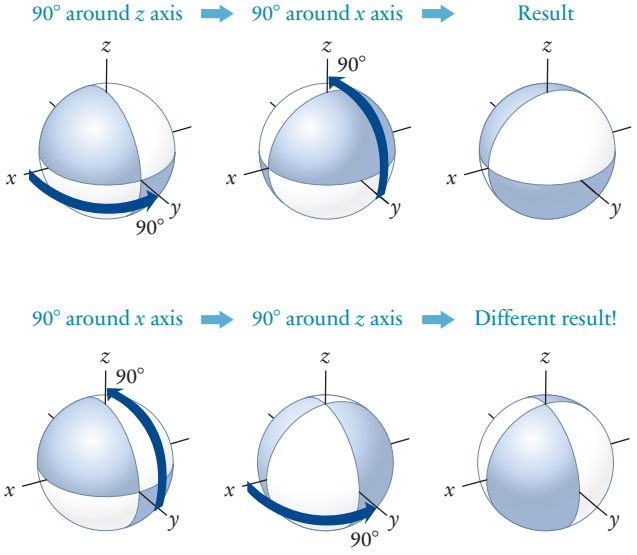
the rotation of disk A points in the positive z direction, and so it has the form $(0, 0, +A)$. The vector representing the rotation of disk B has the form $(0, -B, 0)$, where A and B are positive numbers.



Note that the vector associated with a rotation always lies along the axis of that rotation. If you invert the direction of rotation, the vector points in the opposite direction along the axis. For example, if disk A in Figure 12.17 were rotating in the opposite direction from the one illustrated, you'd have to curl your fingers in the opposite direction, and so your thumb would point in the negative z direction, opposite the direction shown.

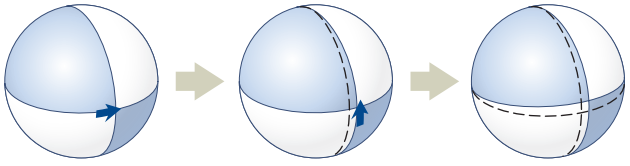
Regardless of your observation angle, the right-hand rule always yields the same direction for a given rotation. Suppose, for example, that you are tightening bolts into a plate as in **Figure 12.18**. When you tighten a bolt, it is natural to consider the bolt's rotation as being clockwise because you usually look at the head of the bolt when tightening it. Now imagine tightening a bolt on the backside of the plate by reaching around it. From where you stand, you must turn in a *counterclockwise* direction to tighten that bolt! The statement "to tighten a bolt, you must rotate it in a clockwise direction" holds only when you are facing the head of the bolt. As Figure 12.18 shows, however, when you align your right-hand thumb in the direction you want the bolt to move, your fingers curl in the correct direction, regardless of where you stand relative to the plate.

The right-hand rule can be used to determine not only the direction of a vector representing a rotation but also the other way around. Given a vector, we can use the right-hand rule to determine the corresponding rotation (**Figure 12.19**). Either one uniquely determines the other.



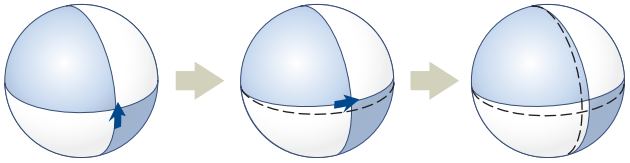
What kind of a vector is the vector we have just introduced? All the vector quantities we have encountered up to now are derived from the displacement vector—an arrow that points from an object's initial

Figure 12.19 The right-hand rule used two ways.



position to its final position. As we've seen, displacement vectors obey a commutation principle: The sum of several displacements is independent of the sequence in which the displacements are added. Displacement vectors commute in two and in three dimensions. Do rotational displacements commute? Rotations in a plane do, as you can easily verify by adding two angles. The result is independent of the order in which the two angles are added: $15° + 23° = 23° + 15° = 38°$. As **Figure 12.20** illustrates, however, rotations in three dimensions do not commute: If you give a beach ball two successive rotations over 90° angles about perpendicular axes, the final orientation of the ball depends on

Figure 12.20 Rotational displacements are not commutative: The order in which you perform them matters.



CONCEPTS

Figure 12.21 Successive rotations over very small angles are commutative. The dashed lines show the initial positions of the ball's seams.

For successive rotations over very small angles, order doesn't matter.

the sequence of the rotations. So, rotational displacements cannot be vectors because in three dimensions $\vartheta_1 + \vartheta_2 \neq \vartheta_2 + \vartheta_1$.

If, instead of rotating the ball twice over 90° angles, you rotate it over two small angles θ_1 and θ_2, the difference in the ball's final orientation is much smaller. As **Figure 12.21** shows, for two successive rotations over 6° angles, the difference is no longer noticeable. Why small angles commute can be understood by looking at **Figure 12.22**, which shows a close-up of the displacement of the seams on the ball in Figure 12.21. Each rotational displacement $\Delta\vartheta$ corresponds to a displacement over an arc of length $\Delta s = r\,\Delta\vartheta$, where r is the radius of the ball. For very small rotational displacements $d\vartheta_1$ and $d\vartheta_2$, the corresponding arcs ds_1 and ds_2 are approximately straight lines on a nearly flat surface. The smaller the angles θ_1 and θ_2, the more the arcs behave like vectors in two dimensions and so commute.

So, infinitesimally small rotational displacements do commute: $d\vartheta_1 + d\vartheta_2 = d\vartheta_2 + d\vartheta_1$ This means that rotational velocity—the rate at which the rotational displacement changes, $\omega = d\vartheta/dt$—obeys the commutation law: $\omega_1 + \omega_2 = \omega_2 + \omega_1$. We can therefore introduce a *rotational velocity vector* $\vec{\omega}$ whose direction is given by the right-hand rule and whose magnitude is ω. The rotational velocity vector is the basic vector describing rotational motion, much as displacement is the basic vector for translational motion. **Figure 12.23** shows two spinning tops with their rotational velocity vectors. Each vector determines the orientation of the top's axis of rotation, the direction in which the top rotates around this axis, and the rotational speed. The arrow representing the rotational velocity of top A is longer than the arrow of top B, indicating that A spins faster than B. We shall examine the vector nature of other rotational quantities in Section 12.8.

Vectors associated with a direction of rotation are called **axial vectors;** vectors derived from the displacement vector are called **polar vectors.** Axial vectors play an important role in physics, not only in rotation but also in electricity and magnetism.

12.7 Suppose the rotation of top A in Figure 12.23 slows down without a change in the direction of its axis of rotation. (*a*) In which direction does the vector $\Delta\vec{\omega}$ point? (*b*) Can the top's rotational acceleration be represented by a vector? If so, in which direction does this vector point?

CONCEPTS

Figure 12.22 Detail of the balls of Figure 12.21 in their final orientation. Because the displacements along the arcs corresponding to each rotation are nearly straight lines, the rotations commute.

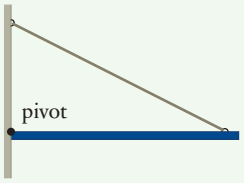
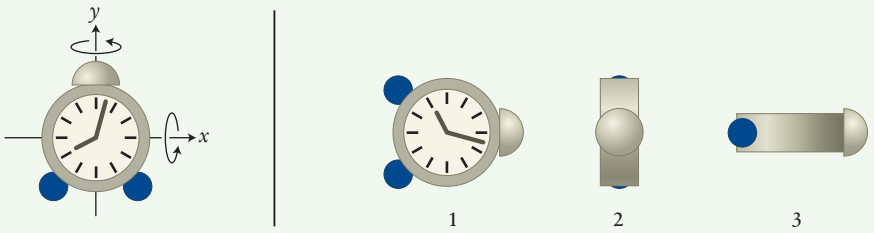
Self-quiz

1. A rope supports one end of a beam as shown in **Figure 12.24**. Draw the lever arm distance for the torque caused by the rope about the pivot.
2. Draw a free-body diagram and an extended free-body diagram for (*a*) a door hanging on two hinges and (*b*) a bridge supported from each end, with a car positioned at one-quarter of the bridge's length from one support.
3. Which diagram in **Figure 12.25**—1, 2, or 3—shows the alarm clock on the left after it has been rotated in the directions indicated by (*a*) 90° about the *x* axis and then 90° about the *y* axis and (*b*) 90° about the *y* axis and then 90° about the *x* axis? Does the order of the rotation change your answer?

Figure 12.24





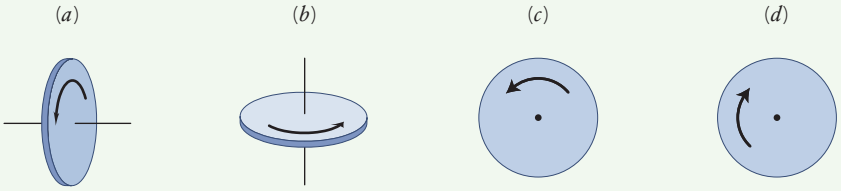


Figure 12.25

4. Give the direction of the rotational velocity vector associated with each spinning object shown in **Figure 12.26**.

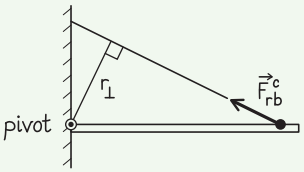

Figure 12.26

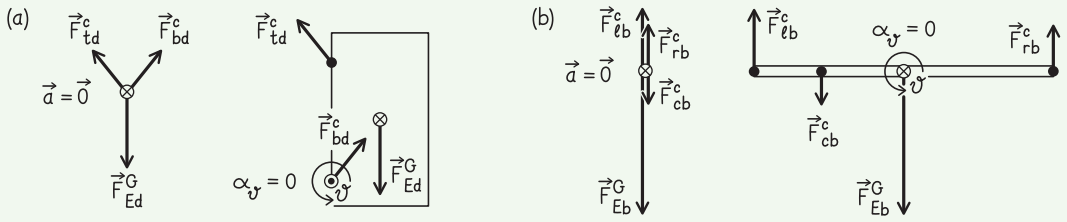
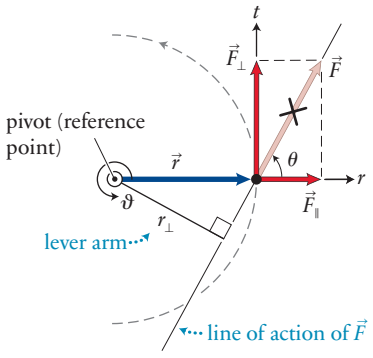
Answers



1. The lever arm distance $r_\perp$ is the perpendicular distance between the pivot and the line of action of the force exerted by the rope on the beam, as shown in **Figure 12.27**.

Figure 12.27



2. See **Figure 12.28**. (*a*) The door interacts with three objects: Earth, the top hinge, and the bottom hinge. Without the top hinge, the force of gravity would tend to rotate the door about an axis perpendicular to the door through the bottom hinge. The force exerted by the top hinge must balance the clockwise torque caused by the force of gravity about the axis through the bottom hinge. The horizontal components of the forces exerted by the hinges must cancel each other. (*b*) The bridge interacts with four objects: Earth, the right support, the left support, and the car. The upward forces from the supports must balance the downward gravitational forces of the car and the bridge. Because these forces must also counteract the counterclockwise torque caused by the car, the force exerted by the support closer to the car must be greater than the force exerted by the other support.

Figure 12.28

3. (*a*) 3; (*b*) 2. The order of rotation does make a difference.
4. Wrapping the fingers of your right hand in the direction of spin gives rotational velocity vectors that point (*a*) to the right, (*b*) up, (*c*) out of the page, and (*d*) into the page.

Figure 12.29 A force $\vec{F}$ is exerted on a particle that is constrained to move in a circle.

12.5 Conservation of angular momentum

In Section 11.5 we saw that angular momentum is a conserved quantity and that the angular momentum of a system rotating in a plane on which no tangential forces are exerted remains constant. Let us now examine how tangential forces are related to the concept of torque introduced in the first part of this chapter and derive mathematical expressions that relate the various rotational quantities and torque.

Consider the situation shown in **Figure 12.29**. A force $\vec{F}$ is exerted on a particle of inertia m that is constrained to move along a circular trajectory of radius r about a pivot. Because $\vec{F}$ has a component that is tangential to the circular trajectory, the particle speeds up. In the language we developed in the first part of this chapter, the particle's rotational acceleration is nonzero because $\vec{F}$ causes a torque on the particle about the pivot. The magnitude of this torque, which we denote by the Greek letter τ (*tau*), is given by

$$\tau \equiv rF \sin\theta = r_\perp F = rF_\perp, \tag{12.1}$$

where θ is the angle between the radius vector $\vec{r}$ and $\vec{F}$ and where $F_\perp$ is the magnitude of the tangential component of the force: $F_\perp = |F_t|$. Because torque is the product of a force and a distance, it has SI units of newton-meters (N · m). Work, being the product of displacement and force, has the same units. Torque and work represent two very different and unrelated quantities, however. Work corresponds to the transfer of energy by a force; torque is the ability of a force to change the rotational motion of an object. To avoid confusion, we shall always use joules for work and newton-meters for torque.

Let us now relate this torque to the particle's tangential acceleration a_t (which is perpendicular to the radius vector $\vec{r}$). This acceleration is given by

$$F_t = ma_t. \tag{12.2}$$

Combining Eqs. 12.1 and 12.2, we obtain

$$\tau_\vartheta = r(ma_t), \tag{12.3}$$

where the subscript ϑ means that τ_ϑ is a signed quantity. Although strictly speaking τ_ϑ is the component of a torque *vector,* we shall refer to it simply as torque. The algebraic sign of the torque is determined by the sign of the rotational acceleration it causes. The torque caused by the force $\vec{F}$ in Figure 12.29, for example, is positive because it causes the particle to accelerate in the positive ϑ direction ($a_t > 0$).

As we saw in Chapter 11, the tangential acceleration is related to the rotational acceleration by $a_t = r\alpha_\vartheta$, so we can write

$$\tau_\vartheta = rm(r\alpha_\vartheta) = mr^2\alpha_\vartheta. \tag{12.4}$$

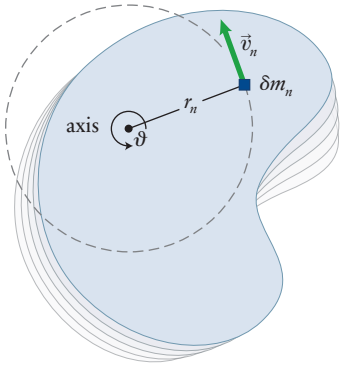
The quantity mr^2 is the rotational inertia of the particle, so Eq. 12.4 becomes

$$\tau_\vartheta = I\alpha_\vartheta. \tag{12.5}$$

Equation 12.5 shows how the torque caused by a force exerted on a particle relates to the particle's rotational acceleration. Notice the remarkable parallel between Eqs. 12.2 and 12.5: Instead of "force equals inertia times acceleration," we have "torque equals rotational inertia times rotational acceleration." Torque is to rotation what force is to translation, and therefore Eq. 12.5 is sometimes called the *rotational equation of motion.*

To find a similar expression for extended objects, consider the rotating extended object illustrated in **Figure 12.30**. Imagine breaking down the object into small particles of inertia δm_n, with each particle located a distance r_n from the axis and having velocity $\vec{v}_n$. Let each particle be subject to a torque $\tau_{n\vartheta}$ about the axis; this torque is caused by forces exerted by surrounding particles and by external forces. For each particle we can write an expression analogous to Eq. 12.4:

$$\tau_{n\vartheta} = \delta m_n \, r_n^2 \, \alpha_{n\vartheta}. \tag{12.6}$$



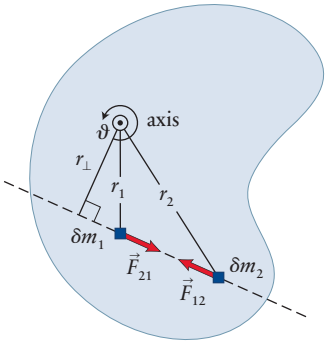
The sum of the torques on all particles is then

$$\sum_n \tau_{n\vartheta} = \sum_n (\delta m_n r_n^2 \alpha_{n\vartheta}) = \left(\sum_n \delta m_n r_n^2 \right) \alpha_\vartheta, \tag{12.7}$$

where we have used the fact that all particles in a rigid rotating object must have the same rotational acceleration α_ϑ. The sum on the right side is the rotational inertia I of the extended object (Eq. 11.42), and so Eq. 12.7 becomes

$$\sum_n \tau_{n\vartheta} = I\alpha_\vartheta. \tag{12.8}$$

Figure 12.30 A rigid object constrained to rotate about an axis.



The sum on the left side contains torques caused by external forces (*external torques* for short) and internal torques. To find the contribution from internal torques, consider two interacting particles within the extended object, as illustrated in **Figure 12.31**. Because particles 1 and 2 interact with each other, they exert forces on each other that are equal in magnitude: $F_{12} = F_{21}$. As Figure 12.31 shows, the lever arm distance for the two forces is the same ($r_\perp$), and so the torque caused by $\vec{F}_{12}$ is equal in magnitude to the torque caused by $\vec{F}_{21}$ but opposite in direction. Their sum is therefore zero:

$$\tau_{21\vartheta} + \tau_{12\vartheta} = r_\perp F_{21} - r_\perp F_{12} = r_\perp (F_{21} - F_{12}) = 0. \tag{12.9}$$

Because this cancellation holds for all pairs of interacting particles within the object, all internal torques drop out of the sum on the left side of Eq. 12.8. Only torques caused by external forces remain. The expression we obtain for an extended object is therefore identical to that for a particle:

$$\Sigma\tau_{\text{ext}\,\vartheta} = I\alpha_\vartheta. \tag{12.10}$$

Figure 12.31 The internal torques caused by two interacting particles within a rotating rigid object have the same lever arm distance, so they cancel.

Another useful expression can be obtained by recognizing that the particle's rotational velocity and rotational acceleration are related by

$$\alpha_\vartheta = \frac{d\omega_\vartheta}{dt}. \tag{12.11}$$

Substituting this expression into Eq. 12.10 and recalling that angular momentum $L_\vartheta = I\omega_\vartheta$ (Eq. 11.34), we get

$$\Sigma\tau_{\text{ext}\,\vartheta} = I\frac{d\omega_\vartheta}{dt} = \frac{d}{dt}(I\omega_\vartheta) = \frac{dL_\vartheta}{dt}, \tag{12.12}$$

where we have used the fact that the rotational inertia I of a rigid object is constant. So torque is the time rate of change of angular momentum, much

as force is the time rate of change of momentum. Equation 12.12 shows that if the sum of the torques caused by external forces exerted on an object is zero, the object's angular momentum does not change:

$$\Sigma\tau_{\text{ext}\,\vartheta} = \frac{dL_\vartheta}{dt} = 0 \quad \Rightarrow \quad \Delta L_\vartheta = 0. \tag{12.13}$$

Whenever the sum of the torques caused by the forces exerted on an object is zero—in other words, whenever its angular momentum is constant—the object is said to be in **rotational equilibrium.** In Chapter 8 we learned that an object is in *translational equilibrium* when its momentum is constant and that this condition is met when the vector sum of the external forces exerted on the object is zero. Now we can expand that notion to include angular momentum, which remains constant when the sum of the torques caused by external forces exerted on it is zero. An object that is in both translational and rotational equilibrium is said to be in **mechanical equilibrium:**

$$\Sigma\tau_{\text{ext}\,\vartheta} = 0 \quad \text{and} \quad \Sigma\vec{F}_{\text{ext}} = \vec{0} \quad \Leftrightarrow \quad \text{mechanical equilibrium.} \tag{12.14}$$

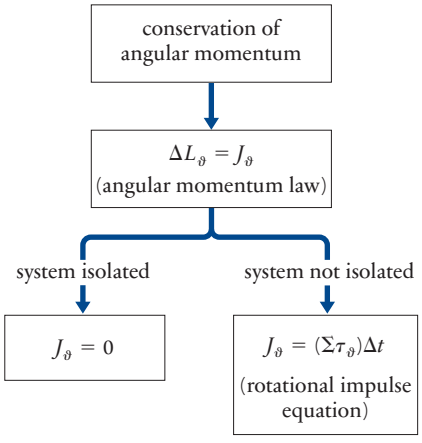
For a system that is not in rotational equilibrium, we have

$$\Delta L_\vartheta = J_\vartheta, \tag{12.15}$$

where J_ϑ represents the transfer of angular momentum from the environment to the system. The quantity J_ϑ is called the **rotational impulse** delivered to the system. Like angular momentum it has SI units of $\text{kg}\cdot\text{m}^2/\text{s}$. In analogy to the momentum law (Eq. 4.18) and the energy law (Eq. 9.1), which embody conservation of momentum and energy, respectively, Eq. 12.15 embodies conservation of angular momentum and is called the **angular momentum law.**

To calculate the rotational impulse, we can use Eq. 12.12. For a system that is subject to constant torques, the time rate of change of the angular momentum is constant, so over a time interval Δt,

$$\Sigma\tau_{\text{ext}\,\vartheta} = \frac{\Delta L_\vartheta}{\Delta t}$$



$$\Delta L_\vartheta = \left(\Sigma\tau_{\text{ext}\,\vartheta}\right)\Delta t. \tag{12.16}$$

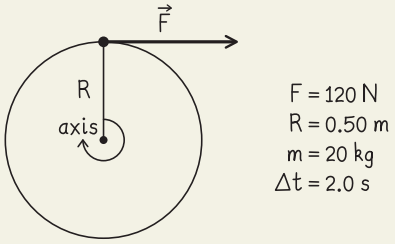
Comparing Eqs. 12.15 and 12.16, we see that the rotational impulse is

$$J_\vartheta = \left(\Sigma\tau_{\text{ext}\,\vartheta}\right)\Delta t \quad \text{(constant torques)}. \tag{12.17}$$

Equation 12.17, called the **rotational impulse equation,** allows us to calculate the change in angular momentum for a system subject to constant external torques. **Figure 12.32** illustrates how conservation of angular momentum gives rise to the angular momentum law and how to treat isolated and nonisolated systems. Notice that the structure of this figure is identical to that of Figure 9.16, which illustrates the same principles for momentum and energy.

Figure 12.32 Angular momentum change for isolated and nonisolated systems.

12.8 Use the conditions of mechanical equilibrium to express $\vec{F}^{\text{c}}_{\text{hf}\,y}$ in Figure 12.11*b* in terms of $\vec{F}^{G}_{\text{Ef}}$ and $\vec{F}^{\text{c}}_{\text{bf}}$. Let the distance between the ball and the pivot be ℓ and the distance from the point where the biceps muscle is attached to the pivot be $\ell/5$.



QUANTITATIVE TOOLS

EXAMPLE 12.5 Flywheel

A motor exerts a constant force of 120 N tangential to the rim of a 20-kg cylindrical flywheel of radius 0.50 m. The flywheel is free to rotate about an axis through its center and runs perpendicular to its face. If the flywheel is initially at rest and the motor is turned on for 2.0 s, how much work does the motor do on the flywheel?

❶ **GETTING STARTED** I begin by making a sketch of the situation to organize the information (**Figure 12.33**). The force exerted by the motor causes the flywheel to start spinning, which means the wheel's rotational kinetic energy changes. This is the only energy change in the system, and I know from the energy law (Eq. 9.1) that $\Delta E = W$. Therefore $\Delta K_{\text{rot}} = W$, and so to calculate the work done by the motor, I need to determine this change in rotational kinetic energy. Because the flywheel is at rest initially, I know that $\Delta K_{\text{rot}} = K_{\text{rot,f}}$.

Figure 12.33

❷ **DEVISE PLAN** To obtain $K_{\text{rot,f}}$, I can use Eq. 11.31, $K_{\text{rot}} = \frac{1}{2}I\omega^2$. The rotational inertia I of the flywheel (which is a solid cylinder) is $\frac{1}{2}mR^2$ (see Table 11.3). Because I'm interested in $K_{\text{rot,f}}$, I need the final value for ω, the wheel's rotational speed. How can I connect ω_{f} to anything I know in this problem? The relationship between ω and angular momentum is $L_\vartheta \equiv I\omega_\vartheta$ (Eq. 11.34), and I know from Eq. 12.16 that $\Delta L_\vartheta = \tau_\vartheta \Delta t$. I know Δt, but do I know anything about τ in terms of the information given—a force, an inertia, and a wheel radius? Yes, Eq. 12.1: $\tau = rF_\perp$. Thus my plan is to express ω_{f} in terms of R and F and then use that expression for ω_{f} in $K_{\text{rot}} = \frac{1}{2}I\omega^2$ to calculate $K_{\text{rot,f}} = W$.

❸ **EXECUTE PLAN** The magnitude of the torque caused by the motor is $\tau = RF$, where R is the radius of the wheel and F is the magnitude of the force exerted by the motor. Equation 12.16 then gives

$$\Delta L_\vartheta = \left(\Sigma\tau_{\text{ext}\,\vartheta}\right)\Delta t = +RF\Delta t.$$

Because the initial angular momentum is zero, I know that $\Delta L_\vartheta = I\omega_{\vartheta,\text{f}} = +I\omega_{\text{f}}$, and so I have

$$\Delta L_\vartheta = RF\Delta t = I\omega_{\text{f}}$$

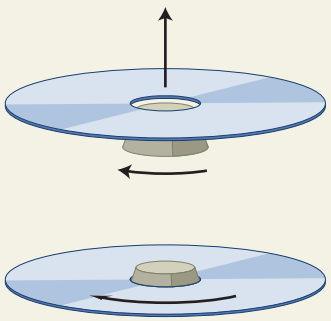
$$\omega_{\text{f}} = \frac{RF\Delta t}{I}.$$

The final rotational kinetic energy is thus

$$K_{\text{rot,f}} = \tfrac{1}{2}I\omega_{\text{f}}^2 = \tfrac{1}{2}I\left(\frac{RF\Delta t}{I}\right)^2$$

$$= \frac{(RF\Delta t)^2}{2I} = \frac{(RF\Delta t)^2}{mR^2} = \frac{(F\Delta t)^2}{m},$$

and the work done on the flywheel is



$$W = K_{\text{rot,f}} = \frac{[(120\text{ N})(2.0\text{ s})]^2}{20\text{ kg}} = 2880\text{ J} = 2.9\text{ kJ}. \checkmark$$

❹ **EVALUATE RESULT** Delivering 2.9 kJ in 2.0 s corresponds to a power of (2.9 kJ)/(2.0 s)=1.4 kW, which is not an unreasonable amount for a large motor.

EXAMPLE 12.6 Spinning disc

Consider the spinning disc shown in **Figure 12.34**, in which, a spinning conical shaft rises up into the opening in the center of the disc, and the disc begins to spin. Suppose the disc's rotational inertia is I_{d}, that of the shaft is I_{s}, and the shaft's initial rotational speed is ω_{i}. Does the rotational kinetic energy of the disc-shaft system remain constant in this process? Assume for simplicity that no external forces cause torques on the shaft.*

Figure 12.34 Example 12.6.

❶ **GETTING STARTED** I am given rotational inertias for a disc and a shaft, plus the initial rotational speed of the shaft, and my task is to determine whether or not the system's rotational kinetic energy changes when these two units interact: $\Delta K_{\text{rot}} \stackrel{?}{=} 0$. The disc is initially at rest, but as the shaft comes in contact with it, the two exert on each other forces that cause torques. The shaft speeds up the rotation of the disc, and the disc slows down the rotation of the shaft. The disc has no rotational velocity before the shaft touches it, and so initially all the system's rotational kinetic energy is in the shaft. After they reach a common rotational speed ω_{f}, both have rotational kinetic energy. I need to calculate the initial and final rotational kinetic energies of the shaft-disc system.

*In reality, the shaft would have to be connected to a motor that keeps it rotating at the correct rotational speed, and thus there would be a force that causes a torque on the shaft.

(Continued)

2 DEVISE PLAN The rotational kinetic energy of a rotating object is given by Eq. 11.31, $K = \frac{1}{2}I\omega^2$. I know the initial rotational speed of the shaft and its rotational inertia, so I can use this equation to calculate the initial rotational kinetic energy of the shaft-disc system. I do not know the final rotational speed of the system, but I do know that because there are no external torques on the system, Eq. 12.13 tells me that the angular momentum must remain constant: $\Delta L_\vartheta = 0$. Expressing ΔL_ϑ as the difference between the final and initial values gives me an expression containing ω_f and ω_i, which means I can probably get an expression for ω_f/ω_i that I can then use to compare the ratio $K_{rot,f}/K_{rot,i}$ and thereby determine whether or not $\Delta K_{rot} = 0$. Because the problem is stated in symbols rather than numerical values, my comparison will be between two algebraic expressions.

3 EXECUTE PLAN Because the torques that the disc and shaft cause on each other are internal and because there are no external torques, I have for the system's angular momentum

$$\Delta L_\vartheta = (I_s + I_d)\omega_{\vartheta,f} - I_s\,\omega_{\vartheta,i} = 0. \qquad (1)$$

If I let the initial direction of rotation of the shaft be positive, $\omega_{\vartheta,i} = +\omega_i$ and so $\omega_{\vartheta,f}$ is also positive. Rearranging terms in Eq. 1, I find that the ratio of the final and initial rotational speeds is

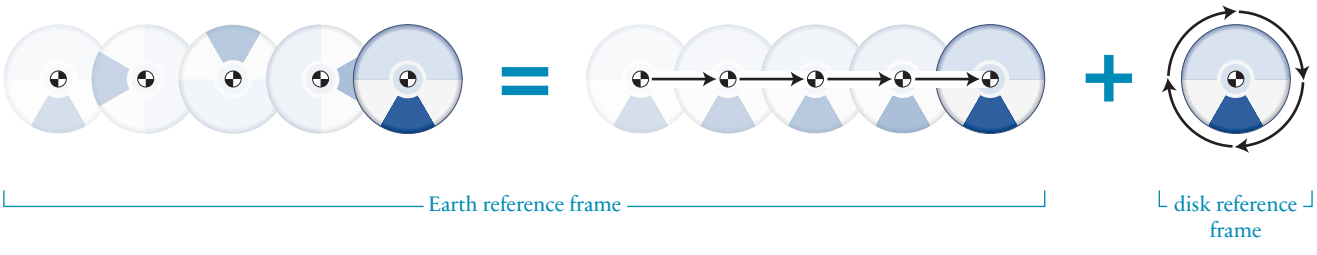
$$\frac{\omega_f}{\omega_i} = \frac{I_s}{I_s + I_d}.$$

The system's initial rotational kinetic energy is $K_i = \frac{1}{2}I_s\,\omega_i^2$, its final rotational kinetic energy is $K_f = \frac{1}{2}(I_s + I_d)\omega_f^2$, and the ratio of the two is

$$\frac{K_f}{K_i} = \frac{\frac{1}{2}(I_s + I_d)}{\frac{1}{2}I_s}\frac{\omega_f^2}{\omega_i^2} = \frac{I_s}{I_s + I_d} < 1,$$

so $K_f < K_i$, or $\Delta K \neq 0$. The rotational kinetic energy of the system is not constant. ✔

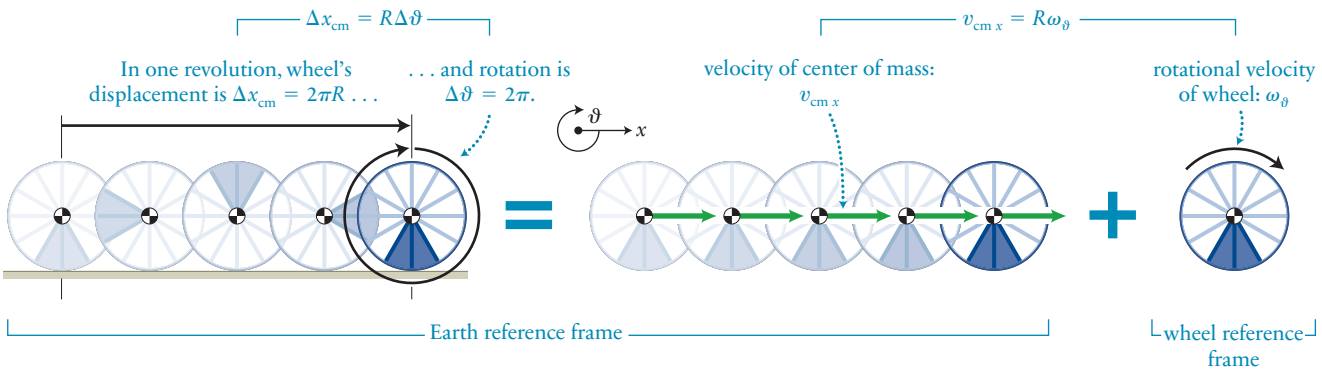
4 EVALUATE RESULT The spinning up of the disc is like an inelastic "rotational collision": The disc initially at rest comes in contact with the spinning shaft, and the two reach a common rotational speed. While the disc is spinning up, some of the system's initial rotational kinetic energy is converted to thermal energy because of friction between disc and shaft, and so it makes sense that the system's rotational kinetic energy decreases.



12.9 Consider the situation in Example 12.6. (*a*) Is the vector sum of the forces exerted by the shaft on the disc nonzero while the disc is spinning up? (*b*) Is the disc isolated?

12.6 Rolling motion

The rotations we have considered so far fall into two classes: rotations about a fixed axis and free rotations. Forces exerted on objects that are constrained to rotate about a fixed axis cause rotational motion only because the axis prevents any translational motion. Forces exerted on freely rotating objects cause both translational motion of the center of mass and rotation about that point. These two motions are *independent* of each other. When you throw a Frisbee, for example, its translational speed v_{cm} is independent of its rotational speed ω (**Figure 12.35**). The Frisbee can have any combination of spin and translational speed: You can throw it so that it spins fast and moves away from you slowly, spins slowly and moves away from you fast, and so on.



The rolling motion of a wheel or ball represents an intermediate case between fixed and free rotations because rolling puts a constraint on the relationship between the translational and rotational motions. Furthermore, a rolling wheel or ball always rotates about its geometric center. We shall restrict our discussion to symmetric objects for which the center of mass is at the geometric center.

Figure 12.35 The translational and rotational motions of a thrown Frisbee are independent of each other.

QUANTITATIVE TOOLS

Figure 12.36 When an object rolls without slipping, its translational and rotational motions are coupled.

Consider the wheel of radius R rolling along a straight line on a flat surface in **Figure 12.36**. To describe this rolling motion we need to choose both a direction of rotation and a direction of the x axis. Usually it is advisable to choose these directions such that a positive change in ϑ corresponds to a positive change in x, as shown in Figure 12.36. If the wheel does not slip, its center advances a distance equal to its circumference, $2\pi R$, during each full revolution. Because the wheel's rotational displacement in one full revolution is 2π, the center-of-mass displacement Δx_{cm} caused by the rolling is related to the rotational displacement $\Delta\vartheta$ by

$$\Delta x_{cm} = R\Delta\vartheta. \tag{12.18}$$

Note that this expression is valid for any displacement; for example, for a quarter revolution $\Delta\vartheta = 2\pi/4 = \pi/2$ and $\Delta x_{cm} = 2\pi R/4 = (\pi/2)R = R\Delta\vartheta$. Dividing the left and right sides by the time interval Δt it takes to advance this distance and taking the limit of both sides for $\Delta t \to 0$ yield

$$v_{cm\,x} = R\omega_\vartheta \quad \text{(rolling motion without slipping)}. \tag{12.19}$$

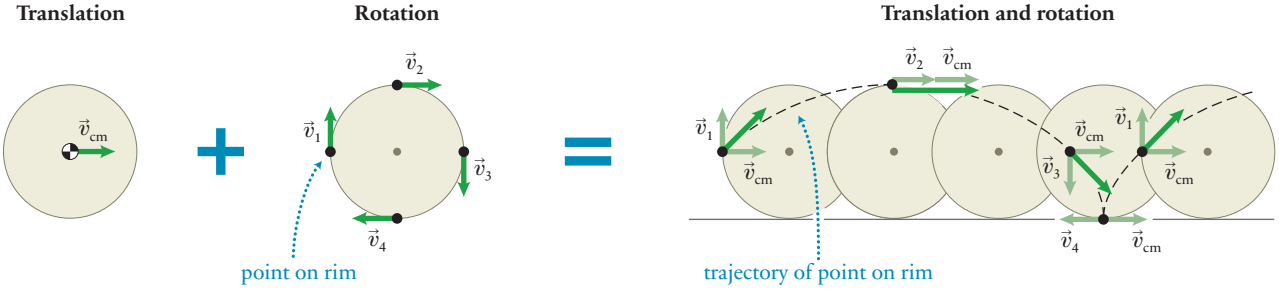
This equation expresses the **condition for rolling motion without slipping.** By coupling the translational and rotational speeds, this condition puts a constraint on the motion of any object that rolls without slipping. Unlike a Frisbee, whose (translational) speed is independent of its rotational speed, the speed of a moving car that is not skidding is proportional to the rotational speed of its wheels.

Equation 12.19 resembles Eq. 11.10 relating the translational and rotational speeds of an object in circular motion:

$$v_t = r\omega_\vartheta. \tag{12.20}$$

These two equations mean very different things, however. Equation 12.19 describes the translational motion of the wheel in the Earth reference frame, whereas Eq. 12.20 gives the tangential speed of any point on the rotating wheel in a reference frame moving along with the center of mass of the wheel. The velocity of a point on the wheel in the Earth reference frame is obtained by adding these two velocities, as shown in **Figure 12.37**. A point on the rim

Figure 12.37 The trajectory of a point on the rim of a rolling wheel. Such a trajectory is called a *cycloid*.



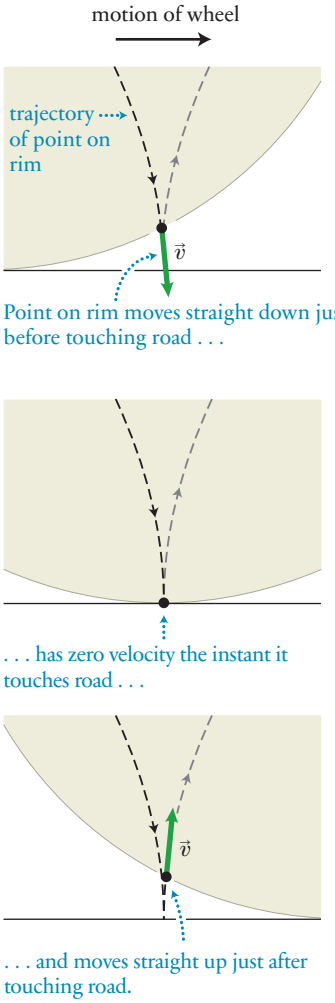


Figure 12.38 The point of contact of a wheel rolling without slipping has zero instantaneous velocity.

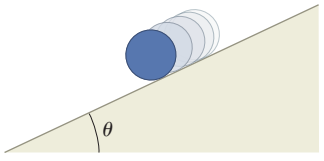
moves with a continuously changing velocity along a trajectory resembling that of the handle of the wrench in Figure 12.9. Note in particular that whenever a point on the rim is in contact with the surface over which the wheel is rolling, that point has zero instantaneous velocity (on the rim $r = R$ and $v_t = r\omega_\vartheta$ points in the direction opposite the direction of $v_{cm} = R\omega$). This zero instantaneous velocity of the rim point in contact with the surface is a direct consequence of the requirement that the object rolls without slipping: The relative velocity of the two surfaces in contact must be zero for there to be no slipping. **Figure 12.38** shows that points on the rim move in a direction perpendicular to the surface just before and just after reaching the bottom.

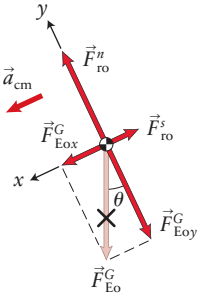
Let us next turn to the dynamics of rolling motion. Suppose a round object of inertia m and radius R is released from rest on a ramp as shown in **Figure 12.39a**. Why does the object roll down instead of sliding down as would a block of wood? The reason is that the force of static friction, which forces the instantaneous point of contact to be motionless, causes a torque about the center of the object. To understand the motion of the object, we must find the vector sum of the forces exerted on it and the sum of the torques caused by these forces. Figure 12.39*b* shows a free-body diagram for the object, which is subject to two forces: the force of gravity and a contact force exerted by the ramp, which has a normal component $\vec{F}^n_{ro}$ in the y direction and a tangential component $\vec{F}^s_{ro}$ in the x direction due to static friction. As we have done with other problems involving ramps, we chose the x axis to be along the ramp. For the object to accelerate down the ramp, the vector sum of the forces must point in the positive x direction, so $\Sigma F_y = F^G_{Eoy} + F^n_{ro} = 0$ and $\Sigma F_x = F^G_{Eox} - F^s_{ro} > 0$. The vector sum of the forces and the center-of-mass acceleration are related by

$$\Sigma F_x = F^G_{Eox} - F^s_{ro} = mg \sin\theta - F^s_{ro} = ma_{cmx}. \qquad (12.21)$$



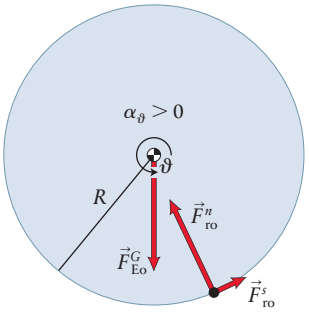
This equation contains two unknowns: the magnitude of the force of static friction F^s_{ro} and a_{cmx}. All we know about F^s_{ro} is that it must be less than or equal to its maximum value $(F^s_{ro})_{max}$, but this fact doesn't help us solve Eq. 12.21. Let us therefore turn to the extended free-body diagram shown in Figure 12.39*c*, which shows the object with the forces exerted on it at their points of application. Because the object rotates about its center of mass, we determine the sum of the torques about the center of mass. Neither $\vec{F}^G_{Eo}$ nor $\vec{F}^n_{ro}$ causes a torque because their lines of action go through the center of mass, and so the lever arm distances for these forces are zero. Only $\vec{F}^s_{ro}$ causes a torque; its lever arm distance is the radius R of the object. Equation 12.10 then yields

$$\Sigma\tau_{ext\,\vartheta} = +F^s_{ro}R = I\alpha_\vartheta, \qquad (12.22)$$



where I is the object's rotational inertia and α_ϑ is its rotational acceleration. Although this yields another equation, we have now added a third unknown: α_ϑ.

Figure 12.39 A round object rolls down a ramp.



(*a*) Object rolls down ramp

(*b*) Free-body diagram

(*c*) Extended free-body diagram

QUANTITATIVE TOOLS

Because the object is rolling without slipping, its rotational and translational motions are coupled, and so its rotational and center-of-mass accelerations must be related. Differentiating both sides of Eq. 12.19, $v_{\mathrm{cm}x} = R\omega_\vartheta$, with respect to time yields

$$a_{\mathrm{cm}x} = R\alpha_\vartheta. \tag{12.23}$$

Substituting α_ϑ from Eq. 12.23 into Eq. 12.22 and solving for F^s_{ro}, we find

$$F^s_{\mathrm{ro}} = \frac{I}{R^2} a_{\mathrm{cm}x}. \tag{12.24}$$

Substituting this result for F^s_{ro} into Eq. 12.21 and solving for $a_{\mathrm{cm}x}$, we obtain

$$a_{\mathrm{cm}x} = +\frac{g\sin\theta}{1+\dfrac{I}{mR^2}} = +\frac{g\sin\theta}{1+c}, \tag{12.25}$$

where $c \equiv I/mR^2$ is the *shape factor* of the object ($0 < c \leq 1$; see Table 11.3). The numerator in Eq. 12.25 is the acceleration of an object sliding down a ramp with negligible friction (see Eq. 3.20). The denominator shows by what factor this acceleration is reduced for rolling motion. Because c is independent of m and R, Eq. 12.25 shows that the acceleration of the object does not depend on the values of m and R. Only the shape of the object matters because it affects the shape factor c. For all objects of a given shape, the time interval to roll down a ramp is thus the same. A large cylinder takes the same time interval as a small one, but a thin cylindrical shell takes longer than a solid cylinder because the shape factor of the shell is greater.

We can now also find an expression for the magnitude of the force of static friction $\vec{F}^s_{\mathrm{ro}}$. Substituting $a_{\mathrm{cm}x}$ from Eq. 12.25 into Eq. 12.24 and eliminating the rotational inertia using $c \equiv I/mR^2$, which gives $I = cmR^2$, we obtain

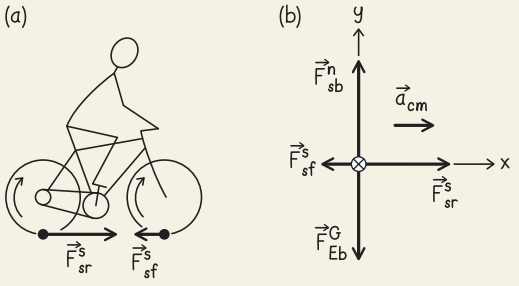
$$F^s_{\mathrm{ro}} = \frac{I}{R^2} a_{\mathrm{cm}x} = \frac{cmR^2}{R^2}\frac{g\sin\theta}{1+c} = \frac{mg\sin\theta}{c^{-1}+1}. \tag{12.26}$$

Note that the force of static friction plays a dual role. It decreases the center-of-mass speed and acceleration of the rolling object by reducing the magnitude of the vector sum of the forces exerted on it: $\sum F_x = F^G_{\mathrm{Eo}x} - F^s_{\mathrm{ro}}$. It also causes the torque that gives the object a rotational acceleration. In the absence of static friction, there would be no torque and objects would never roll—they would only slide.

Wheels certainly make it easier to push objects, but as Eq. 12.26 shows, they do not eliminate friction. In fact, the force of static friction to which wheels are subject slows them down, and as we have seen, the force of static friction can be *greater* than the force of kinetic friction. The next examples help clarify this paradox.

12.10 (*a*) A cylindrical shell and a solid cylinder, made of the same material and having the same inertia m and radius R, roll down a ramp. Is the force of static friction exerted on the shell greater than, smaller than, or equal to that on the solid cylinder? Explain. (*b*) For $\mu_s = 1$, what is the maximum angle of incline θ on which these objects can roll without slipping?

EXAMPLE 12.7 Bicycle friction



As you accelerate from rest on a bicycle, how does the magnitude of the force of friction exerted by the road surface on the rear wheel compare with the magnitude of the force of friction exerted by the road surface on the front wheel? Ignore air resistance, assume both wheels have the same inertia m_w and the same radius R, and let m_{comb} be the combined inertia of you and your bicycle (including both wheels).

❶ **GETTING STARTED** I begin by making a sketch of my bicycle (**Figure 12.40*a***). As I push on the pedals, the chain causes a torque on the rear wheel that makes the wheel rotate so that it exerts a rearward force on the road. Consequently the road surface exerts on the rear wheel a contact force in the opposite direction, and the tangential component of this force—the force of static friction—is what makes the bicycle go forward. This force, which I label $\vec{F}^s_{sr}$, is one of the forces I need for my comparison. (Note the subscripts here: r stands for "rear," not "road"; this is the frictional force exerted by the (road) surface on the rear wheel.)

The front wheel, because it is not connected to the chain, is merely pushed along with the rest of the bicycle. To make this wheel rotate in the right direction, the road surface must exert on it a rearward-pointing force of static friction $\vec{F}^s_{sf}$ (subscript f for "front" here). The torque caused by this frictional force is what makes the front wheel rotate, and this is the second force in my comparison.

Armed with this information, I make a free-body diagram for the bicycle (Figure 12.40*b*), showing the two frictional forces, the upward component of the contact force $\vec{F}^n_{sb}$ exerted by the road surface, and the downward force of gravity $\vec{F}^G_{Eb}$. Because the bicycle accelerates forward, I draw the vector arrow for $\vec{F}^s_{sr}$ longer than the vector arrow for $\vec{F}^s_{sf}$. Finally, I show the direction in which the bicycle's center of mass accelerates and choose a set of axes, letting the x axis point in the direction of motion. I also choose clockwise as the direction of increasing ϑ because that is the direction in which the wheels rotate.

Figure 12.40

❷ **DEVISE PLAN** The equation of motion in the form given by Eq. 8.45, $\vec{a}_{cm} = \Sigma\vec{F}_{ext}/m$, relates the vector sum of the forces shown in my free-body diagram to the acceleration $\vec{a}_{cm}$ of the bicycle's center of mass. Thus this equation gives me an expression that contains the two forces I'm after and seems a good place to begin. This expression contains the translational acceleration, however, whereas the variables in this problem are rotational, so I will probably need Eq. 12.23 relating α_ϑ and a_{cmx}. Focusing on the front wheel first, I can use the rotational equation of motion, Eq. 12.5, $\tau_\vartheta = I\alpha_\vartheta$, to relate the torque caused by $\vec{F}^s_{sf}$ to α_ϑ for this wheel and then use Table 11.3 to express everything in terms of the given variables m_w and R. Once I have my expression for the magnitude F^s_{sf}, I can work with Eq. 8.45 to obtain an expression for F^s_{sr} in terms of F^s_{sf} and make my comparison.

❸ **EXECUTE PLAN** The vector sum of the forces in the x direction is, from Eq. 8.45,

$$\Sigma F_x = F^s_{sr} - F^s_{sf} = m_{comb}\, a_{cmx}, \tag{1}$$

so I have an expression that contains both of the forces I'm after.

According to Eq. 12.23, the rotational acceleration of the rear wheel is $\alpha_\vartheta = a_{cmx}/R$, and the rotational acceleration of the front wheel must be the same as that of the rear wheel. To give the front wheel rotational acceleration α_ϑ, the force $\vec{F}^s_{sf}$ must cause a torque $\tau_\vartheta = I\alpha_\vartheta$ on the wheel, where I is the wheel's rotational inertia. If I treat the wheel as a thin hoop of inertia m_w, I have, from Table 11.3, $I = m_wR^2$, which means the torque on the front wheel is $\tau_\vartheta = m_wR^2\alpha_\vartheta$. The lever arm distance for this torque is equal to the radius R of the wheel, and so for this wheel $\tau_\vartheta = F^s_{sf}R = m_wR^2\alpha_\vartheta$. I know that for both wheels $\alpha_\vartheta = a_{cmx}/R$, however, so I can write

$$F^s_{sf}R = (m_wR^2)\left(\frac{a_{cmx}}{R}\right).$$

Dividing both sides by R yields one of the two forces I must compare:

$$F^s_{sf} = m_w a_{cmx}. \tag{2}$$

This is the magnitude of the force of static friction required to make the front wheel roll when the bicycle has acceleration a_{cmx}. The smaller the inertia of the wheel, the smaller this force magnitude.

Turning to the other force I need for my comparison—the force exerted on the rear wheel—I begin by eliminating a_{cmx} from Eq. 1 using Eq. 2 to get

$$F^s_{sr} - F^s_{sf} = \frac{m_{comb}}{m_w}F^s_{sf}$$

or $$F^s_{sr} = F^s_{sf}\left(1 + \frac{m_{comb}}{m_w}\right) = F^s_{sf}\left(\frac{m_{comb} + m_w}{m_w}\right).$$

The magnitude of the force of static friction exerted on the rear wheel is greater than that exerted on the front wheel by the factor $(m_{comb} + m_w)/m_w$. ✔

❹ **EVALUATE RESULT** Because $m_{comb} \gg m_w$, the magnitude of the force of static friction exerted on the front wheel is much smaller than that on the rear wheel, as I expect.

QUANTITATIVE TOOLS

12.11 (*a*) In Example 12.7, does the force of static friction exerted on the rear wheel cause a torque on the wheel? If so, in which direction? If not, why not? (*b*) In what direction is the sum of the torques on the rear wheel? What does this tell you about the relative magnitudes of the individual torques on the wheel?

12.7 Torque and energy

Torques cause objects to accelerate rotationally and thus cause a change in their rotational kinetic energy. To calculate this energy change, consider the object shown in **Figure 12.41**. A force $\vec{F}$ is exerted at point P on the object, a distance r from the axis of rotation. Let this force be such that the magnitude of its component perpendicular to r remains constant as the object rotates. This component thus causes a constant torque $\tau_\vartheta = +rF_\perp$ about the axis. Equation 12.10 relates the sum of the torques to the rotational acceleration. By applying the chain rule (Appendix B), we can write this equation in the form

$$\Sigma\tau_{\text{ext}\,\vartheta} = I\alpha_\vartheta = I\frac{d\omega_\vartheta}{dt} = I\frac{d\omega_\vartheta}{d\vartheta}\frac{d\vartheta}{dt} = I\frac{d\omega_\vartheta}{d\vartheta}\omega_\vartheta, \tag{12.27}$$

so

$$\left(\Sigma\tau_{\text{ext}\,\vartheta}\right)d\vartheta = I\omega_\vartheta\, d\omega_\vartheta. \tag{12.28}$$

Integrating the left side of this equation yields

$$\int_{\vartheta_\text{i}}^{\vartheta_\text{f}}\left(\Sigma\tau_{\text{ext}\,\vartheta}\right)d\vartheta = \left(\Sigma\tau_{\text{ext}\,\vartheta}\right)\int_{\vartheta_\text{i}}^{\vartheta_\text{f}} d\vartheta = \left(\Sigma\tau_{\text{ext}\,\vartheta}\right)\Delta\vartheta. \tag{12.29}$$

Integrating the right side after pulling the (constant) rotational inertia I out of the integral gives

$$\int_{\omega_{\vartheta,\text{i}}}^{\omega_{\vartheta,\text{f}}} I\omega_\vartheta\, d\omega_\vartheta = I\int_{\omega_{\vartheta,\text{i}}}^{\omega_{\vartheta,\text{f}}}\omega_\vartheta\, d\omega_\vartheta = I\left[\tfrac{1}{2}\omega_\vartheta^2\right]_{\omega_{\vartheta,\text{i}}}^{\omega_{\vartheta,\text{f}}}$$

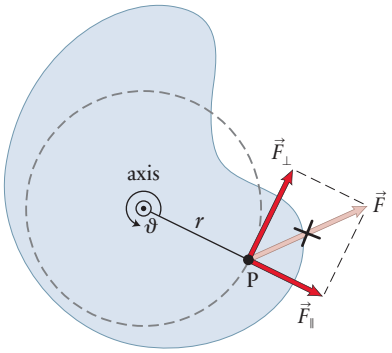
$$= \tfrac{1}{2}I\omega_{\vartheta,\text{f}}^2 - \tfrac{1}{2}I\omega_{\vartheta,\text{i}}^2 = K_{\text{rot,f}} - K_{\text{rot,i}}. \tag{12.30}$$

Equations 12.28–12.30 thus show that the change in the rotational kinetic energy, $\Delta K_\text{rot} \equiv K_{\text{rot,f}} - K_{\text{rot,i}}$, is

$$\Delta K_\text{rot} = \left(\Sigma\tau_{\text{ext}\,\vartheta}\right)\Delta\vartheta \quad \text{(constant torques, rigid object)}. \tag{12.31}$$

This equation states that the change in an object's rotational kinetic energy is equal to the product of the sum of the torques on the object and the object's rotational displacement. Note the analogy to Eq. 9.14, which relates the change in an object's center-of-mass kinetic energy to the product of the vector sum of the forces exerted on it and the object's displacement:

$$\Delta K_\text{cm} = \left(\Sigma F_\text{ext}\right)\Delta x_\text{cm} \quad \text{(constant forces, one dimension)}. \tag{12.32}$$



The kinetic energy of an object or system that is in both translational and rotational motion is equal to the sum of its center-of-mass and rotational kinetic energies:

$$K = K_\text{cm} + K_\text{rot} = \tfrac{1}{2}mv_\text{cm}^2 + \tfrac{1}{2}I\omega^2, \tag{12.33}$$

and the change in this kinetic energy is given by the sum of the changes in Eqs. 12.31 and 12.32:

$$\Delta K = \Delta K_\text{cm} + \Delta K_\text{rot}. \tag{12.34}$$

Figure 12.41 A rigid object subject to a constant torque caused by a force $\vec{F}$ exerted on it undergoes a rotational displacement $\Delta\vartheta$.

EXAMPLE 12.8 Rolling down a ramp

A solid cylindrical object of inertia m, rotational inertia I, and radius R rolls down a ramp that makes an angle θ with the horizontal. By how much does the cylinder's energy increase if it is released from rest and its center of mass drops a vertical distance h?

❶ **GETTING STARTED** I am given information about an object in the shape of a solid cylinder—inertia, rotational inertia, radius, and initial speed—and my task is to find out how much the object's energy has increased once it has rolled down a ramp such that its center of mass has traveled a vertical distance h. The object accelerates down the incline under the influence of the force of gravity. I therefore begin by making a sketch of the situation and drawing both free-body and extended free-body diagrams (**Figure 12.42**). The object is subject to a gravitational force exerted by Earth and a contact force exerted by the ramp. If I choose my axes as shown in my sketch, the contact force exerted by the ramp has a normal component $\vec{F}^n_{ro}$ in the y direction and a tangential component $\vec{F}^s_{ro}$ in the negative x direction due to static friction.

❷ **DEVISE PLAN** As the object rolls, both its translational and rotational kinetic energies increase. Because the shape of the object does not change and because static friction is nondissipative, the object's internal energy does not change. I can use Eq. 12.32 for the change in translational kinetic energy and Eq. 12.31 for the change in rotational kinetic energy. To express the two factors on the right in Eq. 12.32 in terms of my given variables, I use the geometry of the situation to express both factors in terms of $\sin\theta$.

❸ **EXECUTE PLAN** The change in translational kinetic energy is given by Eq. 12.32, $\Delta K_{cm} = \left(\sum F_{ext\,x}\right)\Delta x_{cm}$, and the vector sum of the forces exerted on the object in the x direction is

$$\sum F_{ext\,x} = mg\sin\theta - F^s_{ro}$$

or, using Eq. 12.26,

$$\sum F_{ext\,x} = +mg\sin\theta\left(1 - \frac{1}{1+c^{-1}}\right),$$

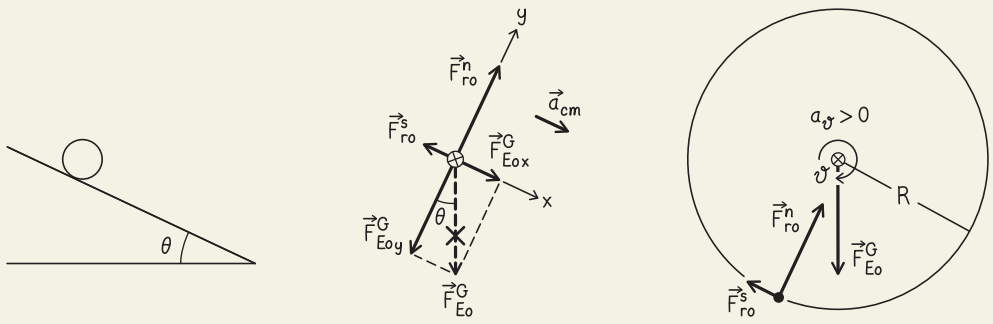
where c is the object's shape factor. Because the displacement of the object's center of mass along the plane is $\Delta x_{cm} = h/\sin\theta$, the change in its translational kinetic energy is

$$\Delta K_{cm} = \left(\sum F_{ext\,x}\right)\Delta x_{cm} = mgh\left(1 - \frac{1}{1+c^{-1}}\right).$$

Next, I use Eq. 12.31 to calculate the change in the object's rotational kinetic energy. From my extended free-body diagram I see that only the force of static friction causes a (positive) torque, so $\sum\tau_{ext\,\vartheta} = +F^s_{ro}R$. I can find the object's rotational displacement $\Delta\vartheta$ from Eq. 12.18:

$$\Delta\vartheta = \frac{\Delta x_{cm}}{R} = \left(\frac{h}{\sin\theta}\right)\left(\frac{1}{R}\right) = +\frac{h}{R\sin\theta},$$

so, from Eq. 12.31,



$$\Delta K_{rot} = (F^s_{ro}R)\left(\frac{h}{R\sin\theta}\right) = \left(\frac{mg\sin\theta}{1+c^{-1}}\right)\left(\frac{h}{\sin\theta}\right) = \frac{mgh}{1+c^{-1}},$$

where I have again used Eq. 12.26 to substitute for F^s_{ro}. Adding the two changes in kinetic energy, I obtain

$$\Delta E = \Delta K_{cm} + \Delta K_{rot}$$
$$= mgh\left(1 - \frac{1}{1+c^{-1}}\right) + mgh\left(\frac{1}{1+c^{-1}}\right) = mgh. \checkmark$$

❹ **EVALUATE RESULT** My result indicates that the object's energy changes by the same amount it would change if it were simply in free fall! In other words, the only work done on the object is the work done by the gravitational force: $\vec{F}^G_{Eo}\cdot\Delta\vec{r} = mgh$ (see Section 10.9). This implies that the work done by all other forces on the object is zero. The normal force does no work on the object because it is perpendicular to the displacement of the object, but what is the work done by the force of static friction on the object? The object's displacement, $h/\sin\theta$, lies along the line of action of the force of static friction, and so it is tempting to write $-F^s_{ro}(h/\sin\theta)$ for the work done by the force of static friction on the object. However, the point of application for $\vec{F}^s_{ro}$ has zero velocity. At each instant, a different point on the object's surface touches the ramp, but the instantaneous velocity of that point is zero. The force displacement for $\vec{F}^s_{ro}$ is thus zero, so the work done by this force on the object is zero as well.

Figure 12.42

QUANTITATIVE TOOLS

Example 12.8 shows that *the force of static friction does no work on a rolling object*! The only thing it does is take away some of the translational kinetic energy and generate an equal amount of rotational kinetic energy. It takes away translational kinetic energy by reducing the magnitude of the vector sum of the forces and converts it to rotational kinetic energy by causing a torque.

12.12 In Figure 12.41, does the force exerted on the rigid object do work on the object?

12.8 The vector product

To complete our treatment of rotation, we must examine the vectorial nature of the rotational components. As we saw in the first part of this chapter, an object's rotational velocity can be described by a vector $\vec{\omega}$. Angular momentum, which is the product of a scalar and $\vec{\omega}$, $\vec{L} = I\vec{\omega}$, is therefore also a vector and points in the same direction as $\vec{\omega}$. Because the rotational acceleration $\vec{\alpha}$ is the time derivative of $\vec{\omega}$, it must be a vector, too. Torque, which is the product of a scalar and $\vec{\alpha}$, $\vec{\tau} = I\vec{\alpha}$, therefore points in the same direction as $\vec{\alpha}$.

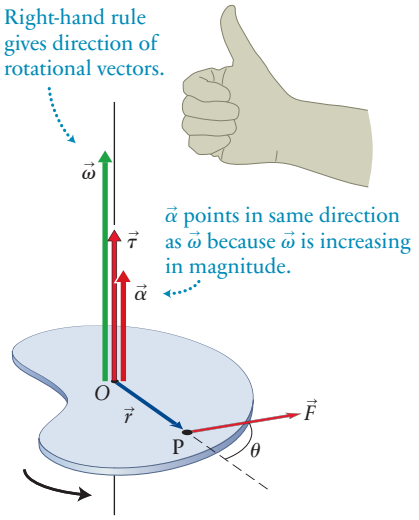
Consider the object in **Figure 12.43**. A force $\vec{F}$ exerted at point P increases the magnitude of the object's rotational velocity about the rotation axis at O. As the magnitude of the rotational velocity increases, the length of the vector representing $\vec{\omega}$ increases. Because the rotation takes place in a plane, the direction of $\vec{\omega}$ remains along the axis of rotation. The direction of $\vec{\alpha}$ is related to the direction of the vector representing the change in rotational velocity $\Delta\vec{\omega}$. Because the direction of $\vec{\omega}$ remains along the axis of rotation, $\Delta\vec{\omega}$, $\vec{\alpha}$, and $\vec{\tau}$ also lie along the rotation axis.

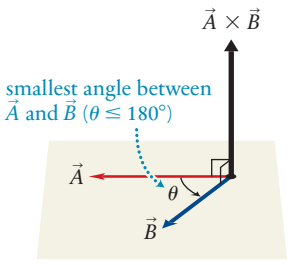
The magnitude of the torque is $rF \sin\theta$, where θ is the angle between $\vec{r}$ and $\vec{F}$. In Section 10.9, I showed that work on a system can be written as a scalar product of two vectors. To account for the vectorial nature of torque, we must introduce a new kind of product of two vectors: one that generates a new vector. Specifically, this product of the vectors $\vec{r}$ and $\vec{F}$ must generate a vector whose magnitude is $rF \sin\theta$ and whose direction is as indicated in **Figure 12.44**. Such a product is called the **vector product.** The vector product of two vectors $\vec{A}$ and $\vec{B}$, written $\vec{A} \times \vec{B}$, is a vector whose magnitude is

$$|\vec{A} \times \vec{B}| \equiv AB \sin\theta, \tag{12.35}$$

where θ is the angle between $\vec{A}$ and $\vec{B}$ when they are placed tail to tail (and $\theta \leq 180°$). The direction of the vector $\vec{A} \times \vec{B}$ is determined as illustrated in Figure 12.44*a*: Place vectors $\vec{A}$ and $\vec{B}$ with their tails together and apply the right-hand rule to the direction of rotation obtained by rotating $\vec{A}$ into $\vec{B}$

Figure 12.43 For a rotation about a fixed axis with increasing rotational speed, the rotational velocity, rotational acceleration, and torque vectors all point along the rotation axis.





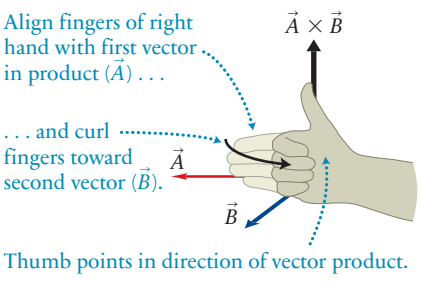


Figure 12.44 The vector product of two vectors.

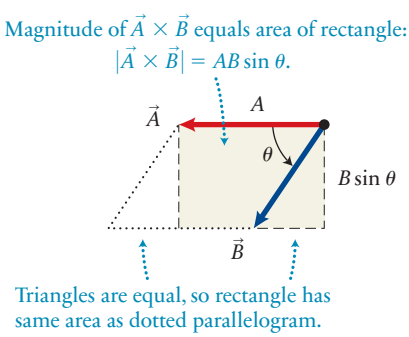

(*a*) Vector product $\vec{A} \times \vec{B}$

(*b*) Finding the direction of a vector product

(*c*) Magnitude of a vector product

through the smallest angle. When you point the fingers of your right hand along the direction of the first vector in the product and curl them toward the direction of the second vector, your thumb points in the direction of the vector product (Figure 12.44*b*).

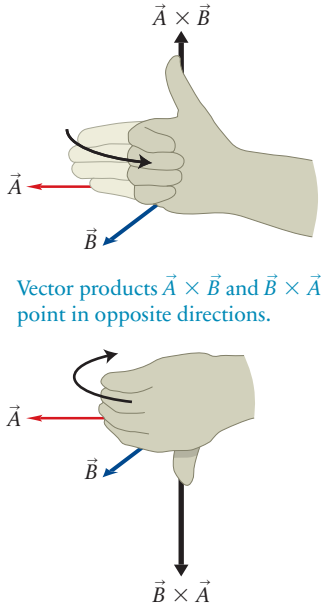

Figure 12.44*c* shows a geometric interpretation of the magnitude of the vector product. The area of the shaded rectangle is equal to $AB \sin\theta$, and because the two triangles are identical, the area of the parallelogram defined by the vectors $\vec{A}$ and $\vec{B}$ is equal to the area of the shaded rectangle. Therefore:

The magnitude of the vector product of two vectors is equal to the area of the parallelogram defined by them.

(The vector product need not have units of area, however.) The magnitude of the vector product is greatest when the two vectors are perpendicular to each other and $\sin\theta = \sin 90° = 1$. When the two vectors are parallel or antiparallel, the parallelogram is reduced to a straight line and the vector product is zero. In particular, the vector product of a vector with itself is zero:

$$\vec{A} \times \vec{A} = \vec{0}. \tag{12.36}$$

Figure 12.45

Vector products $\vec{A} \times \vec{B}$ and $\vec{B} \times \vec{A}$ point in opposite directions.

Another interesting property of the vector product is that the multiplication sequence is important. The vector product $\vec{B} \times \vec{A}$ is equal in magnitude to $\vec{A} \times \vec{B}$ but points in the opposite direction, as shown in **Figure 12.45**:

$$\vec{B} \times \vec{A} = -(\vec{A} \times \vec{B}). \tag{12.37}$$

Using the definition of vector product, we can write the torque about the origin caused by a force $\vec{F}$ as

$$\vec{\tau} = \vec{r} \times \vec{F}. \tag{12.38}$$

You can easily verify that this product has the correct magnitude and direction.

Because torque is the time derivative of angular momentum (Eq. 12.12) and force is the time derivative of momentum (Eq. 8.4), we can write Eq. 12.38 as

$$\frac{d\vec{L}}{dt} = \vec{r} \times \frac{d\vec{p}}{dt}. \tag{12.39}$$

To see what this expression means, we use the product rule (Appendix B) to find the time derivative of the vector product $\vec{r} \times \vec{p}$:

$$\frac{d}{dt}(\vec{r} \times \vec{p}) = \frac{d\vec{r}}{dt} \times \vec{p} + \vec{r} \times \frac{d\vec{p}}{dt}. \tag{12.40}$$

The first term on the right side vanishes because the vector product of a vector and itself is zero:

$$\frac{d\vec{r}}{dt} \times \vec{p} = \vec{v} \times (m\vec{v}) = m(\vec{v} \times \vec{v}) = 0. \tag{12.41}$$

Therefore the right side of Eq. 12.39 is equal to the time derivative of the vector product $\vec{r} \times \vec{p}$:

$$\frac{d\vec{L}}{dt} = \frac{d}{dt}(\vec{r} \times \vec{p}). \tag{12.42}$$

The angular momentum vector can therefore be written as

$$\vec{L} = \vec{r} \times \vec{p}. \tag{12.43}$$

Like the rotational velocity vector, $\vec{L}$ is perpendicular to the plane defined by $\vec{r}$ and $\vec{p}$, a direction in which nothing moves—there is certainly no momentum in this direction.

Because it applies to any type of motion and not just rotational motion, the expression $\vec{L} = \vec{r} \times \vec{p}$ is much more general than $\vec{L} = I\vec{\omega}$. Consider, for example, the motion of the isolated particle in **Figure 12.46**. Because the particle is isolated, its trajectory is a straight line and its momentum is constant. From Eq. 12.35 we see that the magnitude of the particle's angular momentum with respect to the origin O is

$$L = r\,mv \sin\theta = r_\perp mv, \tag{12.44}$$

where θ is the angle between $\vec{r}$ and $\vec{p}$ and $r_\perp$ is the lever arm distance of $\vec{p}$ relative to O. This is the same result we obtained in Chapter 11 (Eq. 11.36). The right side of Eq. 12.44 is indeed constant. Even though $\vec{r}$ changes in direction and magnitude, the lever arm distance $r_\perp$ remains constant. Consequently the product $\vec{r} \times \vec{p}$, perpendicular to the plane defined by O and the particle's trajectory, is unchanged in direction and magnitude.

Figure 12.46 The angular momentum of an isolated particle about an arbitrary point (called origin O here) is constant because $r \sin\theta = r_\perp$ is the same regardless of the position of the particle.

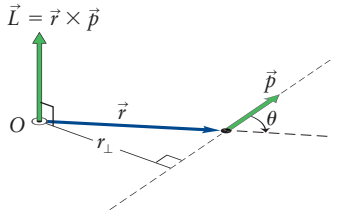

Table 12.1 Translational and rotational dynamics

	Translation	Rotation	Relationship
Momentum	$\vec{p} \equiv m\vec{v}$	$\vec{L} \equiv I\vec{\omega}$	$\vec{L} = \vec{r} \times \vec{p}$
Momentum change	$\Delta\vec{p} = \Sigma\vec{F}_{\text{ext}}\Delta t$	$\Delta\vec{L} = \Sigma\vec{\tau}_{\text{ext}}\Delta t$	
Force	$\Sigma\vec{F}_{\text{ext}} \equiv \dfrac{d\vec{p}}{dt} = m\vec{a}_{\text{cm}}$	$\Sigma\vec{\tau}_{\text{ext}} = \dfrac{d\vec{L}}{dt} = I\vec{\alpha}$	$\vec{\tau} = \vec{r} \times \vec{F}$
Kinetic energy	$K_{\text{cm}} = \frac{1}{2}mv^2$	$K_{\text{rot}} = \frac{1}{2}I\omega^2$	
Kinetic energy change	$\Delta K_{\text{cm}} = \left(\Sigma\vec{F}_{\text{ext}}\right)\Delta\vec{r}_{\text{cm}}$	$\Delta K_{\text{rot}} = \left(\Sigma\tau_{\text{ext}\,\vartheta}\right)\Delta\vartheta$	

Table 12.1 summarizes the results obtained in this chapter and the remarkable parallels between the equations that describe the dynamics of translational and rotational motion. The two sets of equations are mathematically identical given the correspondences in **Table 12.2**. The only new mathematical tool we have introduced in this chapter is the vector product. Apart from this product, which is required to account for the vectorial nature of rotation, the mathematical framework for the two types of motion is identical. Finally, note that—unlike their translational counterparts—rotational inertia, angular momentum, and torque depend on the choice of origin and axis. You should therefore always specify your choice of axis when dealing with these quantities and—most important—consistently use the same axis for the different quantities throughout your calculations.

Table 12.2 Corresponding translational and rotational quantities

position	$\vec{r}$	$\leftrightarrow$	ϑ
velocity	$\vec{v}$	$\leftrightarrow$	$\vec{\omega}$
acceleration	$\vec{a}$	$\leftrightarrow$	$\vec{\alpha}$
inertia	m	$\leftrightarrow$	I

12.13 Consider a particle moving at constant speed along a circular trajectory centered on the origin. Write the relationship of the particle's velocity $\vec{v}$, rotational velocity $\vec{\omega}$, and position vector $\vec{r}$ in the form of a vector product.

Chapter Summary

Torque (Sections 12.1, 12.5)

Concepts The **torque** due to a force exerted on an object is the tendency of the force to give rotational acceleration to the object. The torque about some pivot is the product of the magnitude of the force and the lever arm distance. The SI units for torque are $\mathrm{N \cdot m} = \mathrm{kg \cdot m^2/s^2}$.

An object is in *translational equilibrium* if the vector sum of all the external forces exerted on it is zero. An object is in **rotational equilibrium** if the vector sum of the external torques is zero. If the vector sums of both the forces and the torques are zero, the object is in **mechanical equilibrium.**

Quantitative Tools If $\vec{r}$ is the position vector from a pivot to the location at which a force $\vec{F}$ is exerted on an object and θ is the angle between $\vec{r}$ and $\vec{F}$, the torque τ produced by the force about the pivot is

$$\tau \equiv rF \sin\theta = r_\perp F = rF_\perp, \tag{12.1}$$

where $r_\perp$ is the component of $\vec{r}$ perpendicular to $\vec{F}$ and $F_\perp$ is the component of $\vec{F}$ perpendicular to $\vec{r}$.

Translational equilibrium: $\Sigma\vec{F}_{\mathrm{ext}} = \vec{0}$.

Rotational equilibrium: $\Sigma\tau_{\mathrm{ext}\,\vartheta} = 0$.

Mechanical equilibrium:

$$\Sigma\tau_{\mathrm{ext}\,\vartheta} = 0 \quad \text{and} \quad \Sigma\vec{F}_{\mathrm{ext}} = \vec{0}. \tag{12.14}$$

Rotation of a rigid object (Sections 12.1, 12.2, 12.5–12.7)

Concepts In **free rotation,** an object rotates about its center of mass. The translational and rotational motions are analyzed separately, and the torques and rotational inertia are computed about the center of mass. In *rotation about a fixed axis*, an object is constrained to rotate about a physical axis. Torques and rotational inertia are computed about that axis.

When an object is **rolling without slipping** across a surface, there is no relative motion at the location where the object touches the surface. The object rotates about its geometric center as it translates across the surface. Torques and rotational inertia are computed about the object's center of mass, which for a symmetrical object is the geometric center.

The external force exerted on a rolling object changes the object's center-of-mass kinetic energy. The external torque on a rolling object changes the object's rotational kinetic energy.

Quantitative Tools For both particles and extended bodies, the vector sum of the torques when rotation is about a fixed axis is

$$\Sigma\tau_{\mathrm{ext}\,\vartheta} = I\alpha_\vartheta. \tag{12.10}$$

For an object of radius R that is rolling without slipping, the motion of the center of mass is described by

$$v_{\mathrm{cm}x} = R\omega_\vartheta \tag{12.19}$$

$$a_{\mathrm{cm}x} = R\alpha_\vartheta \tag{12.23}$$

$$\Sigma F_{\mathrm{ext}x} = ma_{\mathrm{cm}x}$$

$$\Sigma\tau_{\mathrm{ext}\,\vartheta} = I\alpha_\vartheta. \tag{12.10}$$

The change in an object's rotational kinetic energy resulting from torques is

$$\Delta K_{\mathrm{rot}} = \left(\Sigma\tau_{\mathrm{ext}\,\vartheta}\right)\Delta\vartheta \quad \text{(constant torques, rigid object)}. \tag{12.31}$$

The kinetic energy of a rolling object is

$$K = K_{\mathrm{cm}} + K_{\mathrm{rot}} = \tfrac{1}{2}mv_{\mathrm{cm}}^2 + \tfrac{1}{2}I\omega^2 \tag{12.33}$$

and the change in the kinetic energy of a rolling object is

$$\Delta K = \Delta K_{\mathrm{cm}} + \Delta K_{\mathrm{rot}}. \tag{12.34}$$

Angular momentum (Sections 12.1, 12.5)

Concepts A **rotational impulse** J_ϑ is the amount of angular momentum transferred to a system from the environment by external torques.

If the sum of the external torques due to forces exerted on a system is zero, the angular momentum of the system remains constant.

Quantitative Tools External torque caused by forces exerted on an object causes the object's angular momentum L_ϑ to change:

$$\Sigma\tau_{\mathrm{ext}\,\vartheta} = \frac{dL_\vartheta}{dt}. \tag{12.12}$$

The **angular momentum law** says that the change in the angular momentum of an object is equal to the **rotational impulse** given to the system:

$$\Delta L_\vartheta = J_\vartheta. \tag{12.15}$$

If the constant external torques on a system last for a time interval Δt, the **rotational impulse equation** says that the rotational impulse is

$$J_\vartheta = \left(\Sigma \tau_{\text{ext}\,\vartheta}\right)\Delta t. \tag{12.17}$$

The law of conservation of angular momentum states that if $\Sigma \tau_{\text{ext}\,\vartheta} = 0$, then $dL_\vartheta/dt = 0$. This means that

$$\Sigma \tau_{\text{ext}\,\vartheta} = \frac{dL_\vartheta}{dt} = 0 \Rightarrow \Delta L_\vartheta = 0. \tag{12.13}$$

Rotational quantities as vectors (Sections 12.4, 12.8)

Concepts A **polar vector** is a vector associated with a displacement. An **axial vector** is a vector associated with a rotation direction. This vector points along the rotation axis, and its direction is given by the **right-hand rule** for axial vectors: When you curl the fingers of your right hand along the direction of rotation, your outstretched thumb points in the direction of the vector that specifies that rotation.

Right-hand rule for vector products: When you align the fingers of your right hand along the first vector in a vector product and curl them from that vector to the second vector in the product through the smaller angle between the vectors, your outstretched thumb points in the direction of the vector product.

The magnitude of the vector product of two vectors is equal to the area of the parallelogram defined by them.

Quantitative Tools The magnitude of the **vector product** of vectors $\vec{A}$ and $\vec{B}$ that make an angle $\theta \leq 180°$ between them when they are tail to tail is

$$|\vec{A} \times \vec{B}| = AB \sin\theta. \tag{12.35}$$

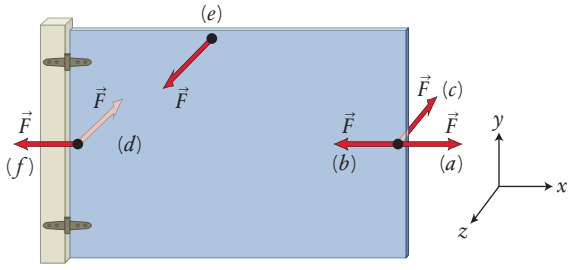
If $\vec{r}$ is the vector from the origin of a coordinate system to the location where a force $\vec{F}$ is exerted, the torque about the origin due to $\vec{F}$ is

$$\vec{\tau} = \vec{r} \times \vec{F}. \tag{12.38}$$

If $\vec{r}$ is the vector from the origin of a coordinate system to a particle that has momentum $\vec{p}$, the angular momentum of the particle about the origin is

$$\vec{L} = \vec{r} \times \vec{p}. \tag{12.43}$$

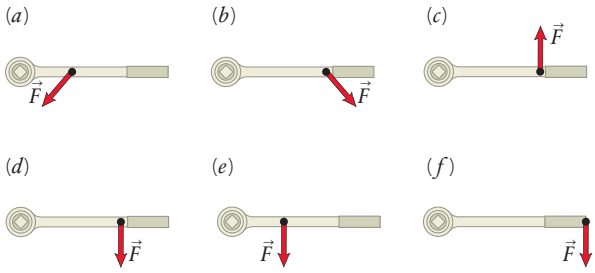
Questions and Problems



For instructor-assigned homework, go to Mastering Physics

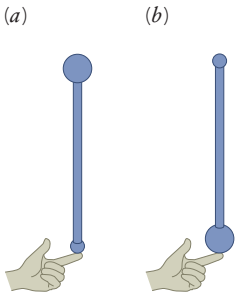
Dots indicate difficulty level of problems: • = *easy,* •• = *intermediate,* ••• = *hard;* CR = *context-rich problem.*

12.1 Torque and angular momentum



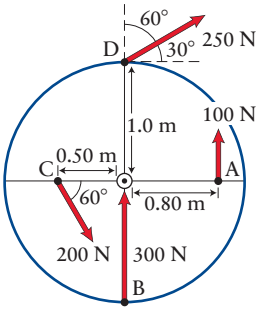
1. To open a stuck jar lid, wearing rubber gloves sometimes works. Why does that help? •
2. You are using a steel crowbar to lift a big rock, with a smaller stone as a fulcrum at the center of the crowbar, but you are not quite able to lift the rock. What can you change about this setup to lift the rock? •
3. The specifications for tightening the bolts on a car engine's valve cover are given in terms of torque rather than in terms of how much force should be exerted on the tightening wrench. Why is torque a better specification here? •
4. When the wrench you are working with does not loosen a nut, you can sometimes succeed by slipping a length of pipe over the end of the wrench and pushing at the end of the pipe. Why does this work? ••
5. In which cases illustrated in Figure P12.5 does pushing in the way and at the location shown cause a torque about a vertical axis passing through the hinges? The dot shows the point of application of the force in each case, and the dashed lines help indicate the line of action of each force. Forces (*a*), (*b*), and (*f*) are exerted parallel to the gate; forces (*c*), (*d*), and (*e*) are exerted perpendicular to the gate. ••

Figure P12.5



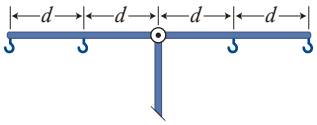
6. Rank, from greatest to smallest, the magnitudes of the torques about the wrench head in Figure P12.6 caused by exerting the same force at the different positions shown. ••

Figure P12.6



7. Which way is easier to balance the asymmetrical baton of Figure P12.7 on your finger? Explain your choice. ••

Figure P12.7



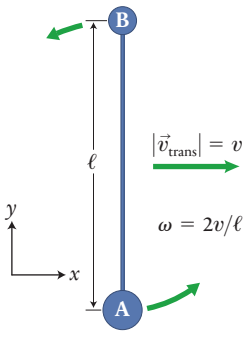
8. Explain why, when a car makes a sharp turn on an unbanked road, the wheels on the inside of the turn tend to come off the ground. ••
9. Figure P12.9 is a top view of a hand-driven carousel in a park. Four parents of the children riding on the device each push on the carousel in different ways. The forces exerted by each of the four parents and the positions at which the forces are exerted are labeled A–D. Rank the parents' pushes in order of increasing magnitude of the torque they cause on the carousel. ••

Figure P12.9

10. The uniform rod shown in Figure P12.10 is fixed to an axis going through its center, so that it is free to rotate clockwise or counterclockwise. It has four hooks: one at each end of the rod and one halfway between the center (axis) and each end. You need to hang four objects from this rod, with one and only one object on each hook, after which the rod must be balanced. The objects have masses M, $3M$, $5M$, and $9M$, respectively. How can this be accomplished? •••

Figure P12.10

12.2 Free rotation

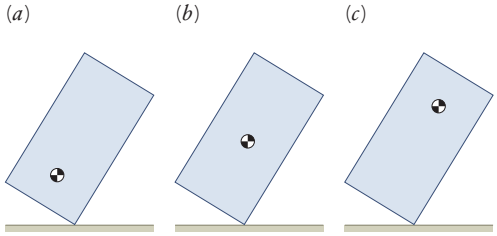


11. A very thin bar of length ℓ and negligible inertia connects two blocks A and B that have inertias $4m$ and m, respectively (Figure P12.11). When this rod-block system is made to spin with no translational motion and no mechanical pivot, each block moves through a circular path in space, with circumferences C_A and C_B. Determine the ratio C_A/C_B. ••

Figure P12.11

12. The system shown in Figure P12.12 consists of two balls A and B connected by a thin rod of negligible mass. Ball A has three times the inertia of ball B and the distance between the two balls is ℓ. If the system has a translational velocity of v in the x direction and is spinning counterclockwise at an angular speed of $\omega = 2v/\ell$, determine the ratio of the instantaneous speeds of the two balls v_A/v_B at the moment shown. ••

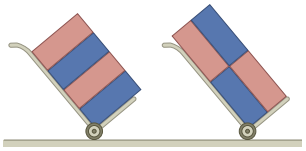
Figure P12.12



13. Put your index fingers about 1 m apart and rest a meterstick or similar object on top of them. Then, while holding the meterstick parallel to the floor, slowly draw your fingers toward each other. You will find that first one finger slips easily under the stick, then the other finger, then the first one again, then the other one again. No matter how much alternating takes place, however, your fingers *always* meet at the center of the stick. Explain what is happening. •••

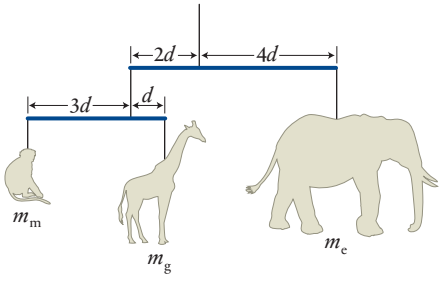
12.3 Extended free-body diagrams

14. To change a light bulb, you climb halfway up a stepladder. Draw an extended free-body diagram for the ladder. •



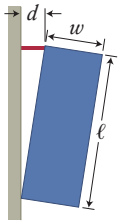
15. Which refrigerator in Figure P12.15 is in the greatest danger of tipping over? Note positions of center of mass. •

Figure P12.15



16. Which configuration of the four uniform boxes in Figure P12.16 makes the hand-truck easier to handle? Explain your answer. ••

Figure P12.16



17. A father and son are carrying a sofa down the stairs, with the son leading. Consider the sofa's center of mass to be at the geometric center. (*a*) Draw an extended free-body diagram for the sofa. (*b*) Who carries the greater share of the load? (*c*) Would your answer to part *b* be the same if the men were carrying instead a sheet of plywood, with its flat sides parallel to the stairs? ••
18. In the mobile in Figure P12.18, what are the inertias of the giraffe and of the elephant in terms of the inertia m_m of the monkey? ••

Figure P12.18

19. A painter leans a ladder at some angle against a smooth wall, with the foot of the ladder resting on wall-to-wall carpeting. Why might the ladder slip as he climbs it? ••
20. You are pushing a cart across the room, and the cart has wheels at the front and the back. Your hands are placed on top of the cart at the center (left to right) of the top edge, pushing horizontally. There is friction between the wheels and the floor. Is the normal force between the floor and the front wheels greater than, smaller than, or equal to the normal force between the floor and the rear wheels? Explain your answer using an extended free-body diagram. ••
21. The top of a ladder of inertia m rests against a smooth wall, and the foot rests on the ground. The coefficient of static friction between ground and ladder is μ_s. What is the smallest angle between the ground and the ladder such that the ladder does not slip? •••
22. A square clock of inertia m is hung on a nail driven into a wall (Figure P12.22). The length of each side of the square is ℓ, the thickness is w, and the top back edge of the clock is a distance d from the wall. Assume that the wall is smooth and that the center of mass of the clock is at the geometric center. Obtain an expression for the magnitude of the normal force exerted by the wall on the clock. •••

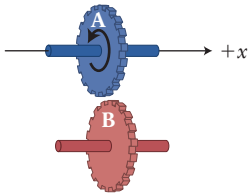


Figure P12.22

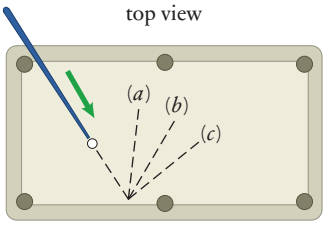
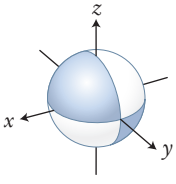
12.4 The vectorial nature of rotation



23. Beginning mechanics sometimes are taught a rule for tightening and untightening bolts: Righty-tighty, lefty-loosey. Explain why this memory device works. •
24. What is the direction of the rotational velocity vector of the jar lid when you open a jar of pickles? •
25. Gear A in Figure P12.25 is spinning such that its rotational velocity vector points in the negative x direction. It is lowered so that its edge comes in contact with the edge of gear B. What is the direction of the rotational velocity caused by the force that A exerts on B? •

Figure P12.25



26. An experienced pool player can control the placement of a ball after it hits an edge bumper by putting spin, or "English," on the ball. This is accomplished by aiming the cue stick so that it hits the ball either left or right of the ball's center. Suppose a player gives a ball English by hitting it to the left of center (left from his perspective). Which path in Figure P12.26 does the ball take after it collides with the bumper? Account for this behavior. ••

Figure P12.26

27. The beach ball shown in Figure P12.27 undergoes a rotation of 90° around the x axis and then a rotation of 90° around the y axis. A second, identically colored ball undergoes first the rotation of 90° around the y axis and then the 90° rotation around the x axis. What additional rotations are necessary to put the second ball in exactly the same orientation as the first? ••

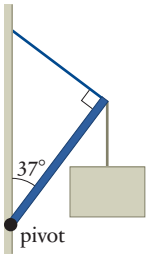


Figure P12.27

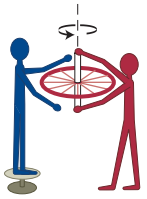
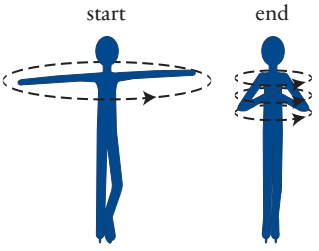
12.5 Conservation of angular momentum



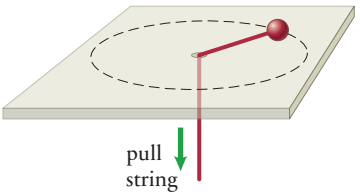
28. Why do quarterbacks throw the football with significant spin about its long axis? •
29. A 1.6-m uniform rod is being used to balance two buckets of paint, each of inertia m, one at each end of the rod. (*a*) Where is the pivot located? (*b*) If paint is removed from one bucket until its inertia is $m/3$, where must the pivot now be placed in order to keep the rod balanced? Ignore the inertia of the rod. •
30. A 0.17-kg turntable of radius 0.15 m spins about a vertical axis through its center. A constant rotational acceleration causes the turntable to accelerate from 0 to 33 revolutions per second in 9.0 s. Calculate (*a*) the rotational acceleration and (*b*) the torque required to cause this acceleration. •
31. A 44-kg child runs at 3.0 m/s tangent to a stationary 180-kg playground merry-go-round that has a radius of 1.2 m. The child then jumps on and grabs hold, causing the merry-go-round to rotate. Determine the resulting rotational velocity of the merry-go-round. ••
32. Standing on the edge of a rotating playground carousel, you take sight on the center of the carousel and walk directly toward that position. (*a*) What happens to the rotational speed of the carousel as you walk? (*b*) In the system consisting of only the carousel (a nonisolated system), any change in angular momentum is due to a torque. Because the hub of the carousel is well lubricated, the only candidate for what causes this torque is the force of friction exerted by your feet on the carousel. "But," you say, "I walked radially inward. How could I possibly cause a torque with my feet?" What's going on? ••
33. Standing with your toes touching the base of a wall, press your nose to the wall and try to stand on tiptoe. What happens and why? ••
34. Draw the angular momentum vector for a tetherball, taking as your origin the center of the pole. Is the angular momentum constant? If not, what force causes the torque that changes the angular momentum? ••
35. Imagine that an asteroid 1 km in diameter collides with Earth. Estimate the maximum fractional change in the length of the day due to this collision. ••
36. You want to hang a 10-kg sign that advertises your new business. To do this, you use a pivot to attach the base of a 5.0-kg beam to a wall (Figure P12.36). You then attach a cable to the beam and to the wall in such a way that the cable and beam are perpendicular to each other. The beam is 2.0 m long and makes an angle of 37° with the vertical. You hang the sign from the end of the beam to which the cable is attached. (*a*) What must be the minimum tensile strength of the cable (the minimum amount of tension it can sustain) if it is not to snap? (*b*) Determine the horizontal and vertical components of the force exerted by the pivot on the beam. ••

Figure P12.36



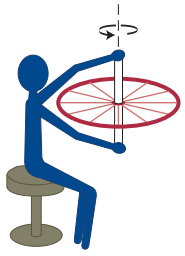
37. The top end of a two-by-four piece of lumber that is 3.0 m long is leaned at a height of 1.8 m against a smooth wall so that the bottom end makes an angle of 37° with the floor. If this board has an inertia of 4.6 kg, what are (*a*) the normal force exerted by the floor on it and (*b*) the normal force exerted by the wall on it? ••
38. Your physics instructor calls you up to the front of the class to be a demonstration assistant. She has you stand on a turntable that is free to rotate and hands you a spinning bicycle wheel, as shown in Figure P12.38. Letting go of the top of the wheel's axle, you then stop its spinning with your free hand. What happens when you stop the wheel? ••

Figure P12.38



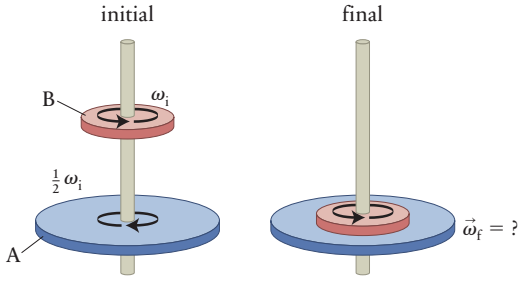
39. Helicopters have a small tail rotor as well as the large main rotor. Why is the tail rotor needed? ••
40. A 35-kg child stands on the edge of a 400-kg playground merry-go-round that is turning at the rate of 1 rev every 2.2 s. He then walks to the center of the platform. If the radius of the platform is 1.5 m, what is its rotational speed once he arrives at the center? ••
41. An ice figure skater starts out spinning at 0.85 revolution per second with her arms outstretched, as shown in Figure P12.41. She wears lightly weighted bracelets to enhance the spin-up effect when she pulls her arms in. (*a*) Calculate her final rotational speed if her rotational inertia is 3.6 kg·m^2 with her arms outstretched and 1.1 kg·m^2 with her arms pulled close to her body. (*b*) Determine the increase in her rotational kinetic energy. (*c*) Where does this added energy come from? ••

Figure P12.41



42. A 25-kg child starts at the center of a playground merry-go-round that has a radius of 2.0 m and rotational inertia of 500 kg·m^2 and walks out to the edge. If the merry-go-round has a rotational speed of 0.20 s^{-1} when she is at the center, what is its rotational speed when she gets to the edge? ••
43. In the setup in Figure P12.43, does pulling the string downward while the ball is revolving make the following properties of the ball increase, decrease, or stay the same: (*a*) angular momentum, (*b*) rotational speed, (*c*) rotational kinetic energy? ••

Figure P12.43

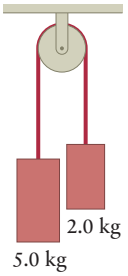


44. Your physics instructor has you sit on a chair that is free to rotate and hands you a spinning bicycle wheel (Figure P12.44). What happens when you flip the wheel over so that the end of the axle that initially pointed up now points down? ●●

Figure P12.44

45. A putty ball of inertia m moving at speed v_i slides on a slick horizontal surface along a path that is perpendicular to the long axis of a rod of length ℓ and inertia $2m$ that is at rest on the surface. The ball collides with one end of the rod and sticks to it. (*a*) Just as the ball sticks, where is the center of mass of the ball-rod system? After the collision, what are (*b*) the magnitude and direction of the velocity of the center of mass and (*c*) the rotational speed of the system? Ignore any effects due to friction. ●●●
46. A 4.5-kg bowling ball is perched on a concrete ledge directly below your dorm room window, with the side of the ball opposite the holes touching the wall. Wanting to hold the ball in place so that it doesn't roll off and land on somebody, you manage to hook one of the holes with a wire and exert a purely tangential (and vertical) force on the ball. If the coefficient of static friction between ball and ledge is the same as that between ball and wall, $\mu_s = 0.50$, what is the maximum upward force you can exert so that the ball does not rotate and you lose your hold? Even though the ball has holes drilled in it, assume a uniform distribution of inertia. ●●●
47. Disk A in Figure P12.47 has radius R_A and thickness h and is initially rotating clockwise, as viewed from above, at $\omega_i/2$. Disk B, made of the same material as A, has radius $R_B = R_A/2$ and thickness h, and is initially rotating counterclockwise at ω_i. The two disks are constrained to rotate about the same axis, which runs through their centers. There is friction between the disks, and so once B slides down and touches A, they spin at the same rotational speed. (*a*) What is their common final rotational velocity? (*b*) If the frictional force is the only force that causes the system to lose energy, what is the fractional change in the kinetic energy? ●●●

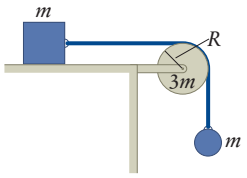
Figure P12.47



48. A 25-kg ladder of length 5.0 m leans against a smooth wall and makes an angle of 50° with the ground. A 75-kg man starts to climb the ladder. If the coefficient of static friction between ground and ladder is 0.50, what distance along the ladder can the man climb before the ladder starts to slip? ●●●

12.6 Rolling motion

49. An object rolls without slipping onto a surface where the coefficient of friction between object and surface is twice as great as that needed to prevent slipping. Describe the subsequent motion. ●
50. To get better acceleration, you want to reduce the inertia of your bicycle. You have your choice of spending $45 on only one of three light-alloy items, each reducing the inertia of your bicycle by the same amount: a new seat post, a new set of pedals, or a new set of wheel rims. Which is the best buy? ●
51. A 3.0-kg solid ball rolls without slipping down a ramp inclined to the horizontal at an angle of 30°. What are (*a*) the acceleration of the ball's center of mass and (*b*) the magnitude of the frictional force exerted on the ball? ●●
52. A 5.0-kg solid cylinder of radius 0.25 m is free to rotate about an axle that runs along the cylinder length and passes through its center. A thread wrapped around the cylinder is pulled straight from the cylinder so as to unwrap with a steady tensile force of 20 N. As the thread unwinds, the cylinder rotates and there is no slippage between thread and cylinder. If the cylinder starts from rest at $t_i = 0$, calculate (*a*) its rotational velocity at $t_f = 5.0$ s and (*b*) the angle through which it has turned at $t_f = 5.0$ s. Ignore any friction in the axle. ●●
53. A disk and a hoop roll down an inclined plane. If the plane is inclined at an angle of 30° from the horizontal, what is the minimum coefficient of friction required so that neither object slips? ●●
54. A 2.0-kg solid cylinder of radius 0.45 m rolls without slipping down a ramp inclined at an angle of 60° to the vertical. Calculate (*a*) the acceleration of the cylinder's center of mass, (*b*) the cylinder's rotational acceleration, and (*c*) the time interval required for it to travel 35 m down the incline if it starts from rest. (*d*) What is the rotational velocity of the cylinder at the end of the time interval found in part *c*? ●●
55. Two cans of pumpkin roll down a loading dock ramp. They have identical inertias, but one of them has a larger radius (and a shorter length) than the other. Which one, if either, makes it down the ramp first? ●●
56. You deliver a horizontal impulse to a cue ball with a cue stick while playing pool. If the ball is to roll without slipping, at what height h above its center (in terms of its radius R) must you strike it? ●●●
57. Two balls of the same radius and same inertia roll down an inclined plane, starting from rest. One ball is hollow, and the other is solid. What is the ratio of the time intervals the two balls require to reach the bottom? ●●

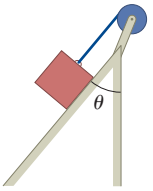


58. In the Atwood machine shown in Figure P12.58, the pulley radius is 0.10 m, and the rotational inertia of the pulley is 0.15 kg·m^2. Calculate (*a*) the acceleration of the blocks, (*b*) the tension in the cord on the left, and (*c*) the tension in the cord on the right. Ignore the cord's inertia. •••

Figure P12.58

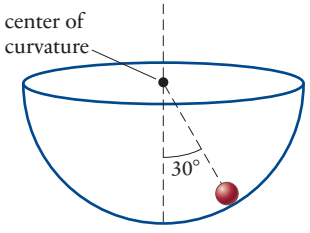
59. A block of inertia m sits on a smooth surface (Figure P12.59). A light string is attached to it and placed over a solid pulley of inertia $3m$ and radius R, and a ball of inertia m is attached to the free end of the string. (*a*) If there is no slippage between string and pulley, determine the magnitude of the block's acceleration. (*b*) If you detach the ball and pull down on the hanging string with a force of magnitude mg, what is the magnitude of the block's acceleration? •••

Figure P12.59



60. A 320-g can of soup is 10.8 cm tall and has a radius of 3.19 cm. (*a*) Calculate the can's rotational inertia about its axis of symmetry, assuming the can to be a solid cylinder. (*b*) When released from rest at the top of a ramp that is 3.00 m long and makes an angle of 25° with the horizontal, the can reaches the bottom in 1.40 s. What is the value of rotational inertia obtained from this experiment? (*c*) Compare the calculated and experimentally determined rotational inertias and suggest possible reasons for the difference. •••

12.7 Torque and energy



61. A 0.30-kg solid cylinder is released from rest at the top of a ramp 1.0 m long. The cylinder has a radius of 0.10 m, and the ramps is at an angle of 18° with the horizontal. What is the rotational kinetic energy of the cylinder when it reaches the bottom of the ramp? •
62. A solid 40 kg cylinder initially at rest has a radius of 0.10 m. What minimum work is required to get the cylinder rolling without slipping at a rotational speed of 25 s^{-1}? •
63. A 1.0-kg ring with an inner radius of 0.060 m and an outer radius of 0.080 m is sent rolling without slipping up a ramp that makes an angle of 30° with the horizontal. If the initial speed of the ring is 2.8 m/s, how far along the ramp does it travel before it comes to a stop? ••
64. A certain car engine delivers enough force to create 380 N·m of torque when the engine is operating at 3200 revolutions per minute. Calculate the average power delivered by the engine at this rotation rate. ••
65. A 680-kg disk of radius 1.2 m is mounted on a fixed axle. A force exerted on the disk causes a constant torque that gives the disk a rotational acceleration magnitude of 0.30 s^{-2} for 5.0 s. If the disk had an initial rotational speed of 4.5 s^{-1}, how much work was done to provide the torque, assuming no energy is lost to friction? ••
66. A large steel bar of length ℓ is hinged at one end to a wall. A mechanic holds the other end so that the bar is parallel to the ground and places a penny on the bar right at the end he is holding. (*a*) What is the rotational acceleration of the bar when he lets go? (*b*) Does the penny remain in contact with the bar after it is released? ••
67. A light, unstretchable string is wound around the perimeter of a 4.0-kg disk that has a radius of 0.50 m and is free to rotate about an axle that runs perpendicular to the disk face and through the disk center. A 2.0-kg block is connected to the free end of the string and allowed to slide down a ramp that makes an angle of $\theta = 37°$ with the vertical (Figure P12.67). Calculate the magnitude of the disk's rotational acceleration. Ignore friction between block and ramp. ••

Figure P12.67

68. A 5.0-kg hollow cylinder of radius 0.25 m rotates freely about an axle that runs through its center and along its long axis. A cord is wrapped around the cylinder and is pulled straight from the cylinder with a steady tensile force of 50 N. As the cord unwinds, the cylinder rotates, with no slippage between cord and cylinder. (*a*) Calculate the work done by the tensile force as the cylinder rotates through 1000 rad. (*b*) If the cylinder starts from rest, calculate its rotational speed after it has rotated through 1000 rad. ••
69. A marble of inertia m is held against the side of a hemispherical bowl as shown in Figure P12.69 and then released. It rolls without slipping. The initial position of the marble is such that an imaginary line drawn from it to the center of curvature of the bowl makes an angle of 30° with the vertical. The marble radius is $R_m = 10$ mm, and the radius of the bowl is $R_b = 100$ mm. Determine the rotational speed of the marble about its center of mass when it reaches the bottom. ••

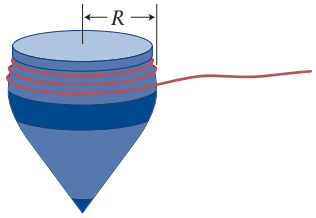


Figure P12.69

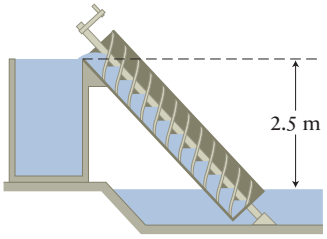
70. A 3.0-kg disk of radius 50 mm rolls down a ramp inclined at an angle of 28° with the vertical. If the disk starts out at rest and the coefficients of static and kinetic friction between the ramp and the disk are both 0.50, what is the rotational speed of the disk after it has traveled 1.5 m? ••



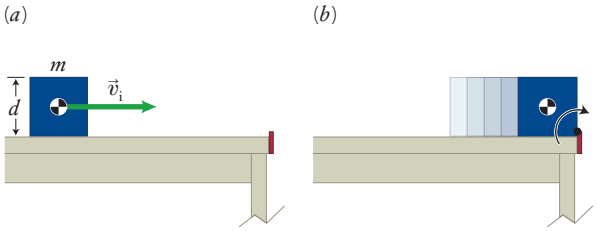
71. An almost-conical toy top (Figure P12.71) that has radius $R = 20$ mm and inertia 0.125 kg is spun up using a force of 5.0 N and a string that is 1.0 m long. What are (*a*) the work done on the top, (*b*) its kinetic energy, and (*c*) its final rotational speed? The shape factor for this top about its axis of symmetry is 0.35. ••

Figure P12.71

72. Archimedes' screw, one of the first mechanical devices invented for lifting water, is a very large screw fitted tightly inside a shaft (Figure P12.72). The bottom of the device is placed in a pool of water. As someone turns the handle to make the screw turn, water is carried up along the ridges of the screw and comes out the top of the shaft and into a storage tank. As the handle turns, the work done by the force exerted on the handle is converted to gravitational potential energy of the water-Earth system. Let's say you want to take a shower using this device. You figure that your shower will use 44 L of water, and so you have to raise this amount to the storage tank 2.5 m above the pool. Every time you turn the handle, you exert a force that causes a torque of 12 N·m. How many times must you turn the handle? ••

Figure P12.72

73. You attach a 0.50-m length of string to a 50-g puck and pass the other end of the string through a hole in the center of a table. Grasping the string under the table, you pull just enough string through the hole so that, when your friend gives the puck a sideways push, it moves in a circle of radius $r_i = 0.45$ m at 1.5 m/s. You then slowly pull on the string, decreasing the circle's radius to 0.20 m. (*a*) What is the puck's speed when $r = 0.20$ m? (*b*) What is the tension in the string as a function of r? What is its value when $r = 0.20$ m? (*c*) How much work is done in moving the puck from the 0.45-m circle to the 0.20-m circle? ••



74. A 30-kg solid sphere of radius 0.12 m is rolling without slipping on a horizontal surface at 2.0 m/s. (*a*) What average torque is required to stop the sphere in 5.0 rev without inducing skidding? (*b*) If this torque is caused by a soft braking bumper that is lowered down until it just makes contact with the top of the sphere, what is the magnitude of the frictional force between bumper and sphere? •••

75. A marble that has a radius of 10 mm is placed at the top of a globe of radius 0.80 m. When released, the marble rolls without slipping down the globe. Determine the angle from the top of the globe to the location where the marble flies off the globe. •••

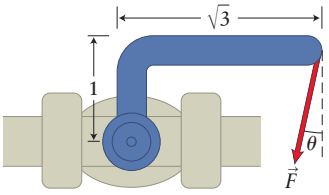
76. A 4.0-kg bowling ball is thrown down the alley with a speed of 10.0 m/s. At first the ball slides with no rotation. The coefficient of friction between ball and alley surface is 0.20. (*a*) How long a time interval does it take for the ball to achieve pure rolling motion? (*b*) What is the ball's translational speed at the end of this time interval? •••

77. You shove a cube of inertia m and side length d so that it slides along a smooth table with speed v_i (Figure P12.77*a*). The cube then hits a raised lip at the end of the table. After it hits the lip, the cube begins to rotate about it (Figure 12.77*b*). (*a*) Show that the magnitude of the cube's angular momentum about the lip before the collision is $L = mdv_i/2$. (*b*) Explain why the angular momentum still has that value at the instant of collision, before the cube has had time to rotate much. (*c*) What is the rotational acceleration of the cube the instant after it hits the lip? (*d*) What maximum initial speed can the cube have so that it does not topple over the lip? •••

Figure P12.77

12.8 The vector product

78. Which of the following expressions make sense: (*a*) $\vec{A} \cdot (\vec{B} \times \vec{C})$, (*b*) $\vec{A} \times (\vec{B} \cdot \vec{C})$, (*c*) $\vec{A} \times (\vec{B} \times \vec{C})$? •



79. When you want to turn a bicycle left, the first thing you do is lean left. Why is it important to do this? •

80. If the magnitude of the vector product of two vectors is the same as the magnitude of the scalar product of the same two vectors, what is the angle between them? •

81. A cyclist exerts a vertical force on a bike pedal. This pedal is at the end of a crank that is 0.20 m long and pivoted to rotate about the axle of the chain wheel. If the cyclist pushes downward with a force of 150 N, determine the magnitude of the torque caused by this force when the crank is (*a*) horizontal, (*b*) 30° from the horizontal, (*c*) 45° from the horizontal, (*d*) 60° from the horizontal, and (*e*) vertical. (*f*) Calculate the average magnitude of this torque exerted by one of the cyclist's feet during one cycle of the pedals, assuming there is no clip holding the cyclist's feet to the pedals. ••

82. The two arms of the L-shaped handle on the spigot of Figure P12.82 have a length ratio of $1:\sqrt{3}$. At what angle θ do you want to pull down on the end of the handle to maximize the torque your force causes? ●●

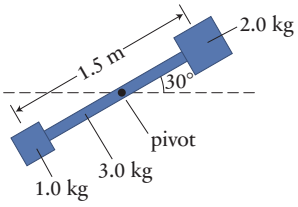


Figure P12.82

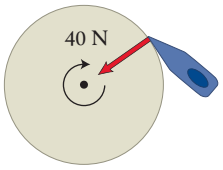
83. Show that, if vectors $\vec{A}$ and $\vec{B}$ are both in an xy plane, $\vec{A} \times \vec{B}$ is a vector that is perpendicular to the xy plane and has magnitude $|\vec{A} \times \vec{B}| = |A_x B_y - A_y B_x|$. ●●

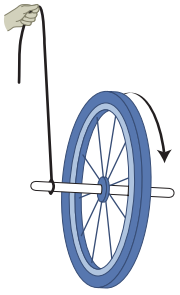
84. A 3.0-kg rod that is 1.5 m long is free to rotate in a vertical plane about an axle that runs through the rod's center, is perpendicular to the rod's length, and runs parallel to the floor. A 1.0-kg block is attached to one end of the rod, and a 2.0-kg block is attached to the other end. At some instant, the rod makes an angle of 30° with the horizontal so that the blocks are in the positions shown in Figure P12.84. (*a*) Determine the torque caused by the forces exerted on the system at this instant. (*b*) Determine the rotational acceleration of the system at this instant. Ignore friction and assume the blocks are small enough that any length they add to the rod can be ignored. ●●

Figure P12.84



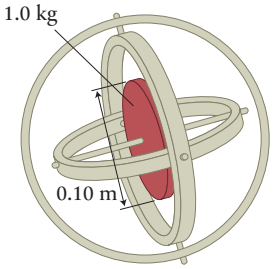
85. A motor drives a disk initially at rest through 23.9 rotations in 5.0 s. Assume the vector sum of the torques caused by the force exerted by the motor and the force of friction is constant. The rotational inertia of the disk is $4.0\ \text{kg} \cdot \text{m}^2$. When the motor is switched off, the disk comes to rest in 12 s. (*a*) What is the torque created by the force of friction? (*b*) What is the torque caused by the force exerted by the motor? ●●

86. The angular momentum of the propellers of a small airplane points directly forward from the plane. (*a*) In what direction do the propellers rotate as seen from the rear of the plane? (*b*) If the plane is flying horizontally and suddenly pulls upward, in which direction does the nose of the plane tend to move? Justify your answer. ●●



87. A 40-kg sharpening wheel of radius 0.10 m is rotating at 3.3 revolutions per second. A 6.0-kg axe is pressed against the rim with a force of 40 N directed as shown in Figure P12.87. Treat the wheel as a disk, and assume a coefficient of kinetic friction between wheel and axe blade of $\mu_k = 0.35$. (*a*) If there is no power source keeping the wheel rotating, how long does it take to stop? (*b*) How many revolutions does the wheel make while it is slowing down? ●●

Figure P12.87



88. A heavy-rimmed bicycle wheel is set spinning in the direction shown in Figure P12.88. A string is tied to one end of the axle, and someone is holding up the string. (*a*) Use torque arguments to explain why the wheel slowly revolves horizontally around the string end of the axle when the free end of the axle is released. (This effect is called *precession*.) (*b*) The precession speed increases as time passes. Explain why. ●●●

Figure P12.88

89. A gyroscope consists of a spinning wheel mounted inside a support structure (Figure P12.89). Because of conservation of angular momentum, the gyroscope keeps its orientation in space unless some outside force causes a torque on it. Suppose the 1.0-kg spinning wheel of a certain gyroscope has a diameter of 0.10 m and is spinning at 14,200 revolutions per minute. What is the magnitude of the torque required to tilt the gyroscope 90° in 20 s such that the spin speed is still 14,200 revolutions per minute when the gyroscope is in its new orientation? ●●●

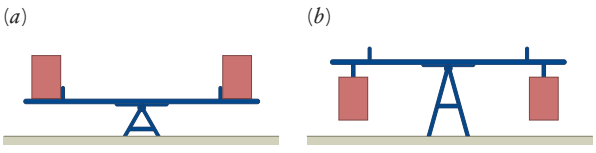


Figure P12.89

Additional Problems

90. Two identical boxes are placed on opposite ends of the board of a playground seesaw as in Figure P12.90*a*, so that the system is in mechanical equilibrium. (*a*) What happens to that equilibrium if you exert a small, brief force, either upward or downward, on either end of the board? (*b*) With the boxes attached to the underside of the board as in Figure P12.90*b* and the system again in mechanical equilibrium, what happens to the equilibrium if you exert such a force on either end? ●

Figure P12.90

91. For the x and y axes of a right-handed Cartesian coordinate system, what is the direction of $\hat{\imath} \times \{\hat{\imath} \times [\hat{\imath} \times (\hat{\imath} \times \hat{\jmath})]\}$? •

92. Standing on a round raft floating on a pond, how do you turn the raft around 180°? •

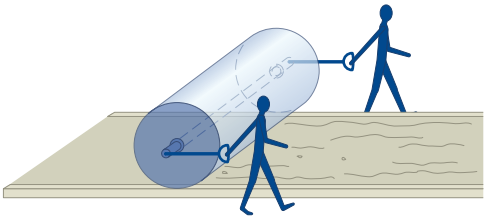
93. Dragster drivers have to avoid supplying too much power to the vehicle because too much power causes the front end to rise in a "wheelie," compromising steering control. (*a*) Why does this happen? (*b*) What advantage comes from having front-wheel drive in a dragster? ••

94. If everyone on Earth simultaneously walked from west to east, by what fraction would the length of the day change? Would it lengthen or shorten? ••

95. A 51-kg box is suspended from the right end of a horizontal rod that has very small inertia. The left end of the rod is affixed to a wall by a pin. A wire connects the right end of the rod to the wall directly above the pin, making an angle of 40° with the rod. (*a*) Calculate the tension in the wire. (*b*) Determine the magnitude of the reaction force the pivot exerts on the rod. (*c*) Repeat parts *a* and *b* for a 10.2-kg rod. ••

96. A 35-kg child stands on the edge of a playground merry-go-round that has a radius of 2.0 m and a rotational inertia of 500 kg · m^2. The merry-go-round has a rotational speed of 0.20 s^{-1} when the child is standing still. If the rotational speed increases to 0.25 s^{-1} when the child starts walking along the edge, with what speed is he walking in the reference frame of the merry-go-round, and in which direction? ••

97. A neutron star is the compact remnant of a very large star that has exploded. Suppose that right after one such explosion, when much of the star's inertia has been blasted away, the star's remaining core has an inertia of 4×10^{30} kg, a radius of 13×10^8 m, and completes one revolution every five days. What is the new spin rate once the core gravitationally collapses into a neutron star of radius 20 km? Assume negligible loss of inertia during the collapse. ••



98. A horizontal 2.0-kg rod is 2.0 m long. An 8.0-kg block is suspended from its left end, and a 4.0-kg block is suspended from its right end. (*a*) Determine the magnitude and direction of the single extra force necessary to keep the rod in mechanical equilibrium. (*b*) At what distance from the left end of the rod must the point of application of this force be? ••

99. What maximum torque can a bicyclist deliver to the pedals? ••

100. A solid ball of inertia m rolls without slipping down a ramp that makes an angle θ with the horizontal. (*a*) What frictional force is exerted on the ball? (*b*) As a function of θ, what coefficient of friction is required to prevent slipping? ••

101. You make a lawn roller out of a 125-kg solid cylinder, set to rotate about a central axle. You rig up handles on either side of the axle so that you and a friend can pull on the handles horizontally to pull the roller in a direction perpendicular to its rotation axis (Figure P12.101). (*a*) If each of you pulls with a horizontal force of 500 N, what is the magnitude a of the roller's acceleration? (*b*) What is the minimum coefficient of static friction necessary to keep the roller from slipping? ••

Figure P12.101

102. A marble is shot across a smooth wooden floor so that the marble both rotates about a horizontal axis and slides. If at a certain instant the marble's rotational kinetic energy equals the translational kinetic energy of its center of mass, what is the ratio of its center-of-mass speed to the speed of a point on its "equator" associated with rotation? ••

103. A 12-kg cylinder of radius 0.10 m starts at rest and rolls without slipping down a ramp that is 6.0 m long and inclined at 30° to the horizontal. When the cylinder leaves the end of the ramp, it drops 5.0 m to the ground. At what horizontal distance from the end of the ramp does it land? ••

104. A child runs in a straight line tangent to a playground carousel, jumps on, and holds tight as the carousel begins to rotate. Which of the following statements is correct for this collision? (*a*) The coefficient of restitution is greater than 1 because there is now rotational energy where there was none before. (*b*) The coefficient of restitution is 1 because the system's translational kinetic energy is completely converted to rotational kinetic energy. (*c*) The coefficient of restitution is less than 1 because the sum of the translational and rotational kinetic energies in the final state is less than the sum in the initial state. (*d*) The coefficient of restitution cannot be defined in a system in which there is both translational motion and rotational motion. (*e*) Explain why all the answers except the one you chose are wrong. ••

105. In a judo hip throw, you pull your 60-kg opponent onto your back to bring her center of mass just above your hip and then rotate her about your hip. Assume that the lever arm distance of your grip on her is 0.30 m from your hip and that her rotational inertia about your hip is 15 kg · m^2. (*a*) What is the magnitude of the pulling force you must exert on her to cause a rotational acceleration of 1.0 s^{-2}? (*b*) What is the magnitude of the pulling force if you throw her from a more upright position, so that the gravitational force has a lever arm of 0.12 m about your hip? •••

106. You've been asked to design a flywheel and the associated emergency friction braking system for an electric vehicle. In order to fit the available space, the flywheel must be cast in the form of a solid steel disk with a thickness of 50 mm and a radius that cannot exceed 0.20 m. For safety purposes, the emergency braking system must slow the flywheel from 6000 revolutions per minute to 0 in 12 revolutions. You know that typical braking systems utilize a pair of "shoes" mounted on calipers to squeeze the thickness of the disc symmetrically near its edge, but you are concerned about how much force the brake shoes might have to exert on the disk. ••• CR

107. A 3.0-kg block is attached to one end of a light, unstretchable string that is wrapped securely around a cylinder that has a 0.30-m radius and a rotational inertia of 0.80 $kg \cdot m^2$. The cylinder is free to rotate about an axle aligned along its long axis. The block is held right alongside the cylinder (so there is essentially no unwound string) and then released from rest. As the block falls, it unwinds the string from the cylinder, with no slippage between string and cylinder. (*a*) Calculate the magnitude of the block's acceleration. (*b*) Calculate the rotational speed of the cylinder after the block has dropped 1.5 m. (Hint: First use the acceleration from part *a* to determine the block's speed.) (*c*) Use energy methods to obtain the cylinder's rotational speed after the block has dropped 1.5 m. (*d*) Calculate the tension in the string after the block has dropped this distance. (*e*) Calculate the instantaneous power delivered by the string and block to the cylinder after the block has dropped this distance. ●●●

108. You are building a pool table and want the design to be such that any ball that rolls into one of the side rails without slipping bounces off the rail and rolls away in another direction, again without slipping. After some experimenting, you decide that you must build the rails to a specific height that is some function of the radius of the balls. (Hint: It seems plausible to assume that the collision is elastic.) ●●● CR

109. A yo-yo is composed of two disks of radius a, with many layers of string wrapped around the axle. The radial distance from the center of the axle to the top layer of string at any instant is b. With the end of the string wrapped around your finger and $b/a \approx 1$, you let the yo-yo drop, unwinding string and ultimately spinning pretty fast when it reaches the bottom of the string $(b/a \approx 0)$. You begin to wonder how the motion of the yo-yo as the string unwinds depends on the value of b. ●●● CR

CONCEPTS

QUANTITATIVE TOOLS

The motion of celestial bodies has fascinated humankind since antiquity. What keeps Earth's Moon, the planets, and other heavenly objects moving along their orbits? Motivated largely by aesthetics, Greek philosophers proposed that celestial bodies move in circles because they believed that circular motion was the most "natural" and the most perfect form of motion. As we have seen, however, moving objects travel in a straight line when they are not subject to any external forces. In the early 17th century, the German astronomer Johannes Kepler suggested that the Sun was somehow driving the planets around their orbits.

If the laws of physics are truly universal, then phenomena on a cosmic scale should follow the same laws that govern objects around us. In this chapter we see that we can indeed apply our notions of mechanics to describe the motion of celestial bodies.

13.1 Universal gravity

Careful analysis of the motion of the Moon and the planets shows that the Moon revolves around Earth and that Earth and the other planets revolve around the Sun at roughly constant speed in nearly circular orbits.* In other words, to a good approximation they move in circular motion at constant speed. These bodies generally rotate about an axis through their centers in addition to revolving around the Sun, but in this chapter we are concerned with their *orbital* motion—that is, rotational quantities associated with the revolving motion of objects.

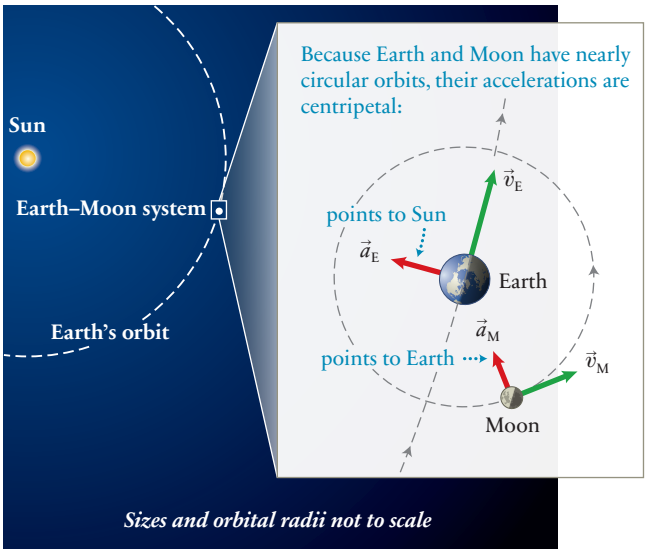
As we saw in Chapter 11, any object that is in circular motion at constant speed has a centripetal acceleration. As illustrated in **Figure 13.1**, in the reference frame of the Sun, Earth has an acceleration that points toward the Sun; in the reference frame of Earth, the Moon has an acceleration that points toward Earth.

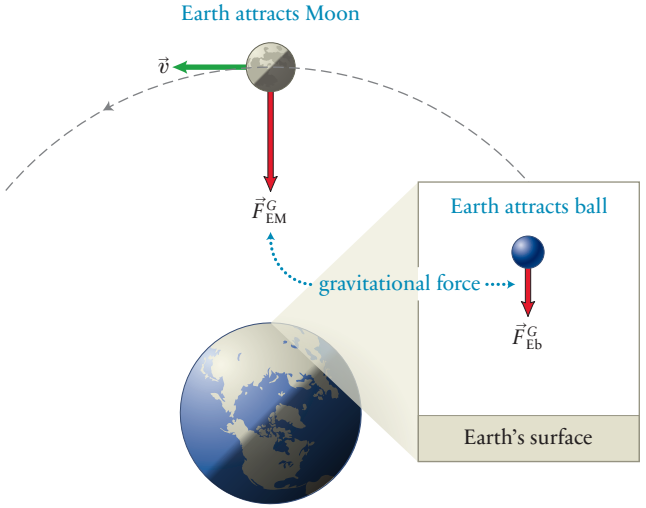
To get some feel for the quantities involved in celestial mechanics, do the following checkpoint before proceeding.

13.1 The orbital period of the Moon around Earth is 27.32 days; that of Earth around the Sun is 365.26 days. (*a*) Which orbit has the greater rotational speed: Earth's or the Moon's? Are the orbital rotational speeds of Earth and the Moon around the Sun great or small relative to the rotational speeds you encounter in daily life? (*b*) The radius of the Moon's orbit around Earth is $R_M = 3.84 \times 10^8$ m; that of Earth's orbit around the Sun is $R_E = 1.50 \times 10^{11}$ m. Which has the greater speed? (*c*) Calculate the centripetal acceleration of Earth in the reference frame of the Sun and the centripetal acceleration of the Moon in the reference frame of Earth. (*d*) How do these accelerations compare with the acceleration due to gravity near Earth's surface?

As we saw in Chapter 11, some force is required to supply a centripetal acceleration. All examples we have considered so far involve contact forces. Neither the Moon nor Earth is in contact with anything, however, and so the force that holds them in orbit must be a field force. In the late 17th century, Isaac Newton made the bold proposal that the force that holds celestial bodies in orbit is a gravitational force—the same force that causes objects near Earth's surface to fall (**Figure 13.2**). Every piece of matter in the universe—feather or planet—attracts every other piece of matter. In other words, a gravitational attraction between Earth and the Moon is responsible for the centripetal acceleration of the Moon, just as a gravitational attraction between a terrestrial object and Earth is responsible for the free

Figure 13.1 Both Earth and the Moon have nearly circular orbits and thus have a centripetal acceleration.





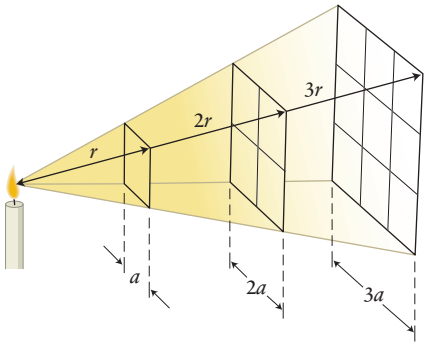


Figure 13.2 The invisible tether that holds the Moon in orbit is, in reality, the same kind of gravitational interaction that causes a ball to fall near Earth's surface. The Moon's orbit is not to scale.

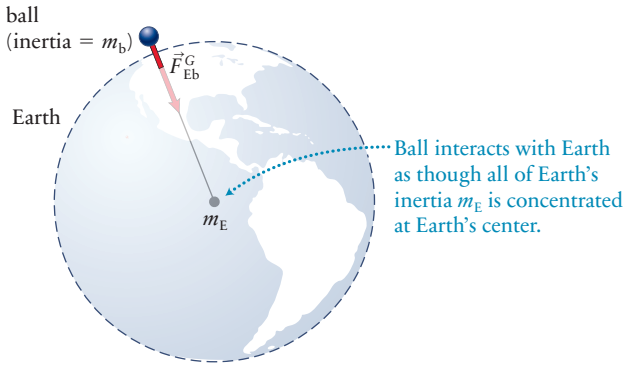
*Earth, for example, moves along an orbit that, to the eye, is indistinguishable from a circle. The speed of Earth along its orbit is constant to within 3%.

CONCEPTS

Figure 13.3 Light that strikes a surface area a^2 located a distance r from the source strikes a surface of area $2a \times 2a = 4a^2$ at a distance $2r$ and a surface of area $3a \times 3a = 9a^2$ at a distance $3r$. The intensity—the amount of light per unit area—decreases with distance r as $1/r^2$.

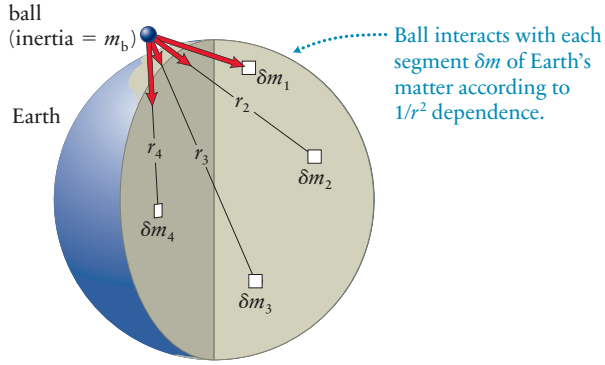
fall of that object. The reason the Moon does not fall to Earth like a freely falling ball is that the Moon has just the right speed to keep moving in a circle around Earth.

Newton furthermore postulated that the effect of gravity weakens with distance, much as the effect of a magnet weakens with distance. If gravity spreads out uniformly from an object, as the rays from a light source do, then the effect of gravity should decrease as $1/r^2$—the inverse of the square of the distance (**Figure 13.3**). The radius of the Moon's orbit is 60 times the radius of Earth, so the gravitational force exerted by Earth on the Moon should be smaller by a factor of $\left(\frac{1}{60}\right)^2$ than the gravitational force exerted by Earth on an object near the ground. An object at the same distance from Earth as the Moon should therefore experience an acceleration due to gravity of magnitude $\frac{1}{3600}g = (9.8\ \text{m/s}^2)/3600 = 0.00272\ \text{m/s}^2$. This value is in excellent agreement with the Moon's centripetal acceleration (see Checkpoint 13.1), confirming the $1/r^2$ dependence of the gravitational force.



There is one catch in this reasoning: The dilution of the gravitational force by a factor of $1/r^2$ assumes that the object near Earth's surface is one Earth radius away from the point of attraction. In other words, a ball falling near the surface of Earth interacts with Earth as if all the matter were concentrated at its center—6378 km below the surface—as illustrated in **Figure 13.4*a***. Yet if all matter interacts gravitationally with a $1/r^2$ dependence, then a piece of Earth-matter near the surface of Earth attracts the ball much more strongly than does a piece of Earth-matter deep inside or on the opposite side of Earth (Figure 13.4*b*). It is certainly not obvious that the forces exerted by all the different pieces of Earth add up to give the same result as in Figure 13.4*a*. Newton, however, proved mathematically that:

A uniform solid sphere exerts a gravitational force outside the sphere with a $1/r^2$ dependence as if all the matter in the sphere were concentrated at its center.

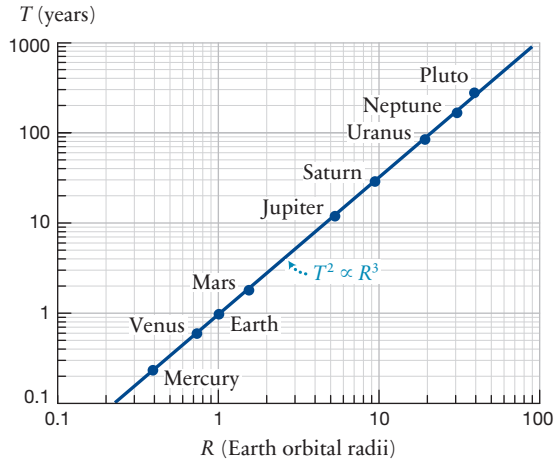


The proof of this statement is given in Section 13.8. A direct consequence of this statement is that the distance between gravitationally interacting spherical objects should always be taken to be the distance between their centers.

Figure 13.4 (*a*) A solid sphere exerts a gravitational force as if all of the sphere's matter were concentrated at the center of the sphere. (*b*) Because the magnitude of the gravitational force between two objects depends on the distance between them, the gravitational forces exerted by the various "chunks" of Earth's interior represented by δm have different magnitudes.

(*a*) Gravitational interaction between Earth and ball near Earth's surface

(*b*) Reason gravitation acts as though from Earth's center



13.2 If the force of gravity decreases with the inverse square of the distance, why were we allowed, in all our earlier work on the gravitational force, to say that an object sitting on the ground, an object sitting in a tree 10 m above the ground, and an object flying at an altitude of 10 km all experience the same 9.8-m/s^2 acceleration due to gravity?

Further evidence of the $1/r^2$ dependence of the gravitational force is provided by the observed relationship between the radii R and the periods T of the planetary orbits. As it orbits the Sun, each planet has centripetal acceleration $a_c = v^2/R$, where $v = 2\pi R/T$ is the planet's linear speed and R is the radius of its orbit. So $a_c = 4\pi^2 R/T^2$ or $a_c \propto R/T^2$.* If this centripetal acceleration is provided by a gravitational attraction exerted by the Sun on the planet, the magnitude of the force (and hence the centripetal acceleration) should decrease

*The symbol $\propto$ means "is proportional to." That is, $a_c \propto R/T^2$ means that there is some constant k such that $a_c = kR/T^2$.

CONCEPTS

Figure 13.5 The planetary period T versus the orbital radius R. The data are plotted on a logarithmic grid to fit the large range of values. To convince yourself of the $T^2 \propto R^3$ dependence, compare the values of T at $R = 1$ Earth orbital radius and $R = 100$ Earth orbital radii.

as $1/R^2$. So, the $1/r^2$ dependence of the gravitational force requires that $a_c \propto 1/R^2$. Combining this result with $a_c \propto R/T^2$, we get $1/R^2 \propto R/T^2$, or $T^2 \propto R^3$. In words:

The square of the period of a planetary orbit is proportional to the cube of the orbit's radius.

Johannes Kepler had established this fact from astronomical data in 1619, providing support for the $1/r^2$ dependence of the gravitational force proposed later by Newton. The excellent agreement with astronomical observations is shown in **Figure 13.5**.

13.3 Suppose the universe were two dimensional rather than three dimensional. (*a*) Following the line of reasoning illustrated in Figure 13.3, describe how the strength of the gravitational force would depend on distance in this flat universe. (*b*) How would the periods of the planetary orbits be related to their radii in this universe?

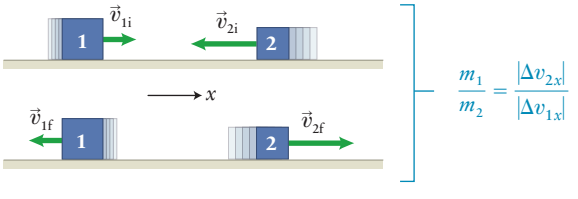
CONCEPTS

What determines the strength of the gravitational attraction? To answer this question, consider two identical lumps of clay, each of inertia m. If we let the lumps fall freely, each is subject to a single downward force of gravity and undergoes an acceleration g. To give each lump this acceleration, Earth must exert a force mg on it. Now imagine combining the two lumps. The double lump has twice the inertia, which means it is twice as hard to accelerate as either single lump. Yet, like any other object near Earth's surface, the double lump undergoes an acceleration g. From this observation, we conclude that Earth pulls twice as hard on the double lump as it does on either single lump. Apparently the gravitational pull on an object is proportional to the quantity of material in it, a quantity called the **mass** of the object. The double lump has twice the mass of either single lump.

The gravitational pull exerted by Earth on an object is proportional to the object's mass.

The acceleration of a freely falling object near Earth's surface does not depend on the type of material: In the absence of air resistance, all objects, regardless of their composition, configuration, or any other property of the object, have the same acceleration in free fall. This observation suggests that the inertia of an object and the force of gravity exerted on it are proportional to each other. Given that the force of gravity is proportional to the object's mass, we can consider mass and inertia to be equal and let the SI unit of mass be the kilogram (kg). As we shall see in the next chapter, this equality between mass and inertia breaks down for motion at very high speeds. In everyday situations, however, we can say:

The mass of an object is equal to the object's inertia.



For the description of everyday situations, therefore, we can denote both by the same symbol m and express each in units of kilograms. Unless we need to refer explicitly to an object's resistance to a change in velocity or account for effects that occur at very high speeds, we henceforth shall call both simply the *mass* of the object.

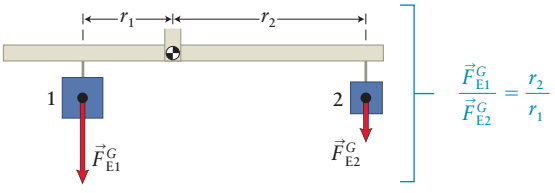
The equality of inertia and mass may seem obvious, but consider the two experiments shown in **Figure 13.6**. The collision experiment in Figure 13.6*a* allows us to determine the ratio of the objects' inertias. Now suppose we suspend the same two objects, from a beam that is supported at its center of mass. We arrange the objects' suspension points so that the beam is balanced as shown in Figure 13.6*b*. Experimentally we discover that for *any* two objects, the ratio m_1/m_2 determined in the first experiment is exactly equal to the ratio r_2/r_1 determined in the second experiment. As we saw in Chapter 12, when the beam is balanced, the torques on the beam add up to zero, so $r_1 F_{E1}^G = r_2 F_{E2}^G$, which means that

$$\frac{F_{E1}^G}{F_{E2}^G} = \frac{r_2}{r_1}.$$

Figure 13.6 Establishing the equivalence between inertia and mass.

(*a*) Collision between objects gives ratio of inertias

(*b*) Beam in equilibrium gives ratio of gravitational forces



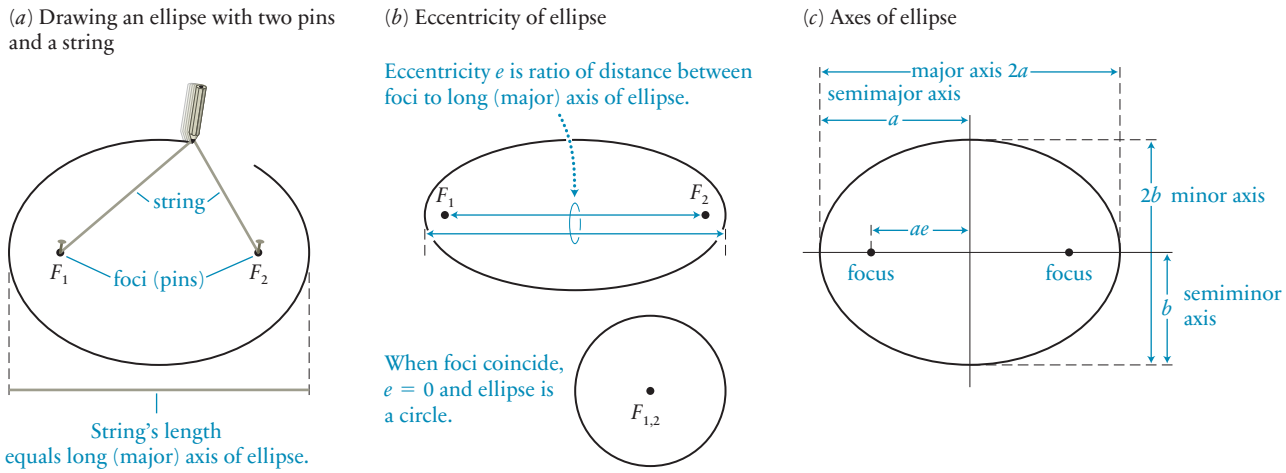


Figure 13.7 Tracing an ellipse. The greater the separation of the foci, the more eccentric (elongated) the ellipse ($0 < e < 1$). In the special case where the two foci coincide ($e = 0$), the ellipse becomes a circle of radius a.

Combining this with the experimental observation that

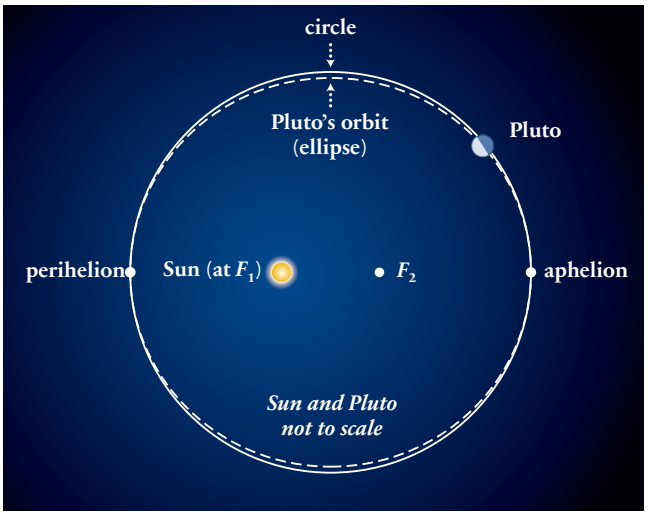
$$\frac{m_1}{m_2} = \frac{r_2}{r_1},$$

we see that

$$\frac{F^G_{E1}}{F^G_{E2}} = \frac{m_1}{m_2}.$$

In words, for any two objects, the ratio of the gravitational forces they experience is equal to the ratio of their inertias. If you think about it, there is no reason to expect this result. The two experiments are completely different: The collision measures the objects' tendencies to resist a change in velocity—their *inertias*—and involves no gravity; the balancing experiment measures the gravitational pull on the objects—their *mass*—and involves no motion. This equivalence is therefore truly remarkable.

Because the gravitational force exerted by Earth on an object is proportional to that object's mass, we can expect the gravitational force exerted by Earth on the Moon to be proportional to the Moon's mass: $F^G_{EM} \propto m_M$. The attraction between Earth and the Moon is mutual, and so symmetry requires the force of gravity exerted by the Moon on Earth to be proportional to the mass of Earth: $F^G_{ME} \propto m_E$. In addition, we know that $F^G_{EM} = F^G_{ME}$, and so the force of gravity must be proportional to the product $m_M m_E$.



Combining this conclusion with the $1/r^2$ dependence, we can now write for the gravitational attraction between any two material objects of masses m_1 and m_2 separated by a distance r:

$$F^G_{12} \propto \frac{m_1 m_2}{r^2}.$$

This is Newton's **law of gravity.** It applies to all the mass in the universe: Every piece of matter attracts every other piece of matter in the universe according to this law.

The $1/r^2$ dependence also explains the shape of the planetary orbits. Using conservation of energy and angular momentum, we can show that the orbit of a body moving under the influence of gravity must be an ellipse (**Figure 13.7**), a circle, a parabola, or a hyperbola. Most comets, for example, move in highly elliptical orbits with the Sun at one focus of the ellipse. The planets also move in elliptical orbits with the Sun at one focus. As you can see from the data in **Table 13.1**, however, the planetary orbits are close to circular, even for dwarf planet Pluto, whose orbit has the greatest eccentricity of all. Even though the effect of the eccentricity on the shape of the orbit is minimal, its effect on the speed is considerable. The Sun is appreciably off-center for Pluto's orbit, and so the distance to the Sun and the speed vary as the planet moves between the closest point to the Sun, the *perihelion*, and the farthest point, the *aphelion* (**Figure 13.8**).

Figure 13.8 In spite of having the greatest eccentricity in Table 13.1, Pluto's orbit (dashed line) is remarkably close to a circle (solid line). Because the Sun is off-center, Pluto's speed varies appreciably along the orbit.

CONCEPTS

†The elliptical orbits of the planets and the Moon are specified by their *semimajor axis a* (half the major axis) and eccentricity *e*; see Figure 13.7. With the exception of Mercury and Pluto, the eccentricity is small and so the orbits are close to being circular.

13.4 Suppose the force of gravity between two objects 1 and 2 of masses m_1 and m_2 were proportional to the sum $m_1 + m_2$ rather than to the product $m_1 m_2$. (*a*) Would this dependence be consistent with the following two requirements? (*i*) The force exerted by 1 on 2 is equal in magnitude to the force exerted by 2 on 1. (*ii*) The force of gravity exerted by Earth on two identical objects is equal to the sum of the forces exerted on the individual objects. (*b*) Can you think of any other combination of m_1 and m_2 that satisfies requirements (*i*) and (*ii*)? (*c*) Suppose you are given a lump of matter of mass *M*. How should you divide this lump into two parts to maximize the force of gravity between the two parts?

CONCEPTS

EXAMPLE 13.1 Comparing gravitational pulls

Compare the gravitational force exerted by Earth on you with (*a*) that exerted by a person standing 1 m away from you and (*b*) that exerted by Earth on Pluto.

1 GETTING STARTED Although I don't know yet how to calculate a numerical value for the gravitational force, I know that the gravitational force between two objects with masses m_1 and m_2 separated by a distance r is proportional to the factor $m_1 m_2 / r^2$. To compare gravitational forces, I should therefore compare these factors for each given situation.

2 DEVISE PLAN My mass is about 70 kg, and I can get the masses of Earth and Pluto from Table 13.1. When I stand on the surface of Earth, the distance between me and the center of the planet is its radius, which is given in Table 13.1. To do part *b*, I need to know the distance between Pluto and Earth, which is not given in the table. Planetary orbits are very nearly circular, however, so I can consider the semimajor axis *a* to be the radius of each (nearly) circular orbit. Table 13.1 shows that the "radius" of Pluto's orbit is about 40 times greater than that of Earth's orbit, and so I make only a small error by taking the Sun-Pluto distance as a measure of the (average) Earth-Pluto distance. Armed with this information, I'll calculate the factor $m_1 m_2 / r^2$ first for Earth and me, then for the two situations described in the two parts of this problem.

3 EXECUTE PLAN When I stand on the surface of Earth, $r = R_E$, and so the factor $m_1 m_2 / r^2$ is

$$\frac{m_1 m_E}{R_E^2} = \frac{(70\ \text{kg})(5.97 \times 10^{24}\ \text{kg})}{(6.38 \times 10^6\ \text{m})^2} = 1.0 \times 10^{13}\ \text{kg}^2/\text{m}^2.$$

(*a*) For two 70-kg people separated by 1 m, I get

$$\frac{m_1 m_2}{r_{12}^2} = \frac{(70\ \text{kg})^2}{(1\ \text{m})^2} = 4.9 \times 10^3\ \text{kg}^2/\text{m}^2.$$

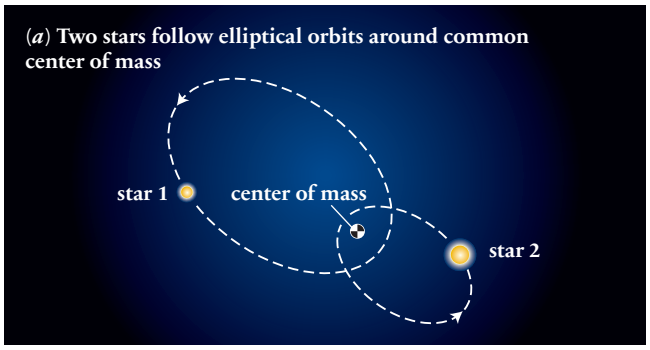
Thus the gravitational force exerted by a person standing 1 m from me is $(4.9 \times 10^3\ \text{kg}^2/\text{m}^2)/(1.0 \times 10^{13}\ \text{kg}^2/\text{m}^2) = 4.9 \times 10^{-10}$ times the gravitational force exerted by Earth on me. ✔

(*b*) For Earth and Pluto, I have

$$\frac{m_E m_P}{r_{EP}^2} = \frac{(5.97 \times 10^{24}\ \text{kg})(1.36 \times 10^{22}\ \text{kg})}{(5.9 \times 10^{12}\ \text{m})^2} = 2.3 \times 10^{21}\ \text{kg}^2/\text{m}^2.$$

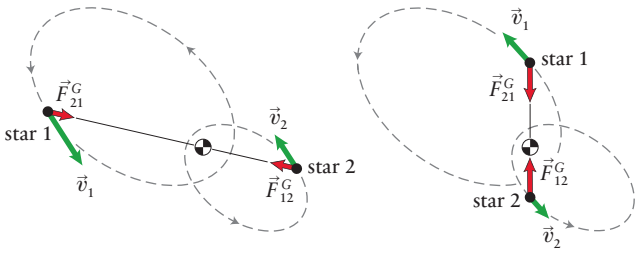
This is $(2.3 \times 10^{21}\ \text{kg}^2/\text{m}^2)/(1.0 \times 10^{13}\ \text{kg}^2/\text{m}^2) = 2.3 \times 10^8$ times greater than the attraction between Earth and me. ✔

4 EVALUATE RESULT That the gravitational force exerted by another person on me is more than a billion times smaller than that exerted by Earth on me makes sense: Only the gravitational attraction between Earth and objects on Earth is noticeable. That the gravitational force exerted by Earth on Pluto is 200,000,000 times greater than that exerted by Earth on me, even though Pluto is 1,000,000 times farther from Earth's center than I am, is amazing. Of course, Pluto's mass is about 10^{20} times greater than mine, and that factor more than makes up for the large difference between the Earth-me distance and the Earth-Pluto distance.



13.5 In part *a* of Example 13.1, what would the distance between the other person and you have to be for the gravitational force between the two of you to match the gravitational force exerted by Earth on you? Is it possible to verify your prediction?

13.2 Gravity and angular momentum



The force of gravity is a **central force**—a force whose line of action always lies along the straight line that connects the two interacting objects. A planet orbiting the Sun, for example, is subject to a force that is always directed toward the Sun. The fact that the force is central has an important consequence for angular momentum.

For example, consider an isolated system of two gravitationally interacting stars of masses m_1 and m_2 (**Figure 13.9**). We choose a coordinate system such that the origin is at the center of mass of the system. Because the system is isolated, the center of mass remains fixed at the origin. This means that the ratio r_1/r_2 of the objects' distances from the center of mass must remain the same regardless of the objects' motion (when $\vec{r}_{cm} = \vec{0}$, $m_1\vec{r}_1 + m_2\vec{r}_2 = \vec{0}$ and so $r_1/r_2 = m_2/m_1$; see Section 6.6). Note how the ratio r_1/r_2 in Figure 13.9 remains constant and how the orbits of the two stars have the same shape (scaled by the factor r_1/r_2).

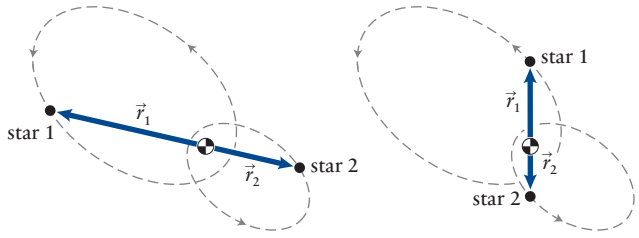


Figure 13.9 Gravitation is a central force, as illustrated by two stars orbiting their common center of mass.

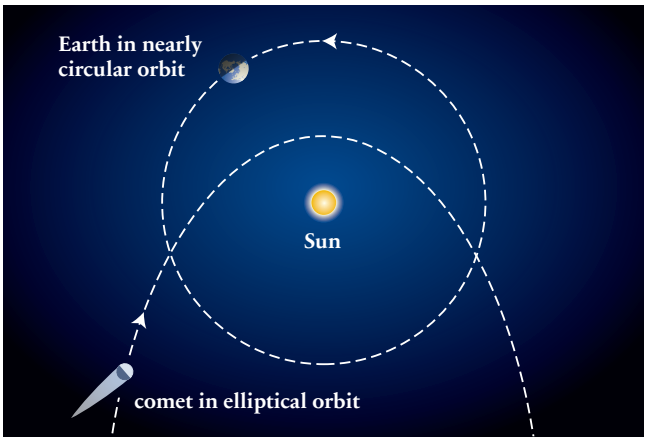
(*b*) Gravitational forces stars exert on each other point along straight line connecting star centers. (Stars are shown at two instants in orbit.)

(*c*) Ratio r_1/r_2 of distances between each star and center of mass remains constant.

Because the center of mass always lies on the line of action of the gravitational forces, the torques caused by each of these forces about the center of mass are zero and therefore the angular momentum of each star about the center of mass doesn't change. So, not only is the angular momentum of the two-star system constant, but the angular momentum of each star about the center of mass is constant, too.

In an isolated system of two objects interacting through a central force, each object has a constant angular momentum about the center of mass.

Often we consider situations in which one of the two interacting objects is much more massive than the other, as shown in **Figure 13.10** on the next page. In that case, the center of mass lies nearly at the center of the more massive object. This permits us to view the situation from the position of the more massive object, which we can consider fixed at the origin. In Figure 13.10*a*, for example, the Earth moves in a nearly circular orbit about the Sun. Because the Sun is so much more massive than Earth, the center of the Sun is very close to the center of mass of the Sun-Earth system. We therefore can ignore the small difference and consider the two centers to coincide. If we consider the orbit to be circular, the center of mass also coincides with the center of the orbit. Figure 13.10*b* shows a comet moving along an elliptical orbit under the influence of a gravitational force exerted by the Sun. The center of mass again lies at the center of the Sun, which is at one of the foci of the ellipse (not at the center of the ellipse).



13.6 (*a*) If we ignore the influence of other celestial objects, the Earth-Sun system is isolated, and so it must rotate about the system's center of mass. Using the data in Table 13.1, determine how far from the center of the Sun the center of mass of the system is and what fraction of the Sun's radius this distance is. (*b*) As it passes the point shown in Figure 13.10*b*, does the comet speed up, slow down, or travel at constant speed? If the trajectory shown is part of an ellipse, where is the comet's velocity greatest? Where is it smallest?

Because the force is central and because the center of mass is at the Sun in Figure 13.10, the angular momentum of each of the orbiting objects about the Sun is constant. The meaning of this statement for a

CONCEPTS

Figure 13.10 Whether an orbit is circular or elliptical, the gravitational force on the orbiting body points toward the Sun. If the orbit is elliptical, the Sun is at one focus, not at the center of the ellipse.

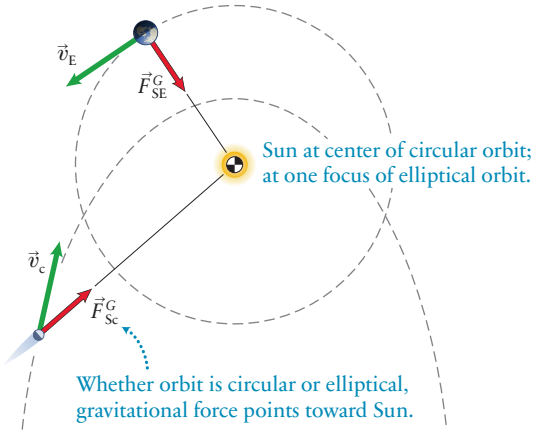

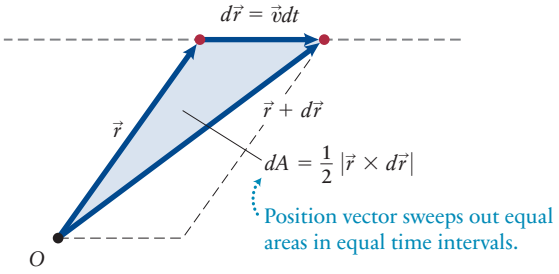

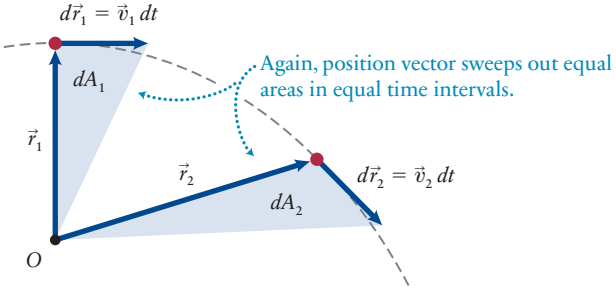

Figure 13.11 The position vectors of an object moving (*a*) with constant momentum along a straight line and (*b*) with constant angular momentum along an arbitrary path sweep out equal areas in equal time intervals.

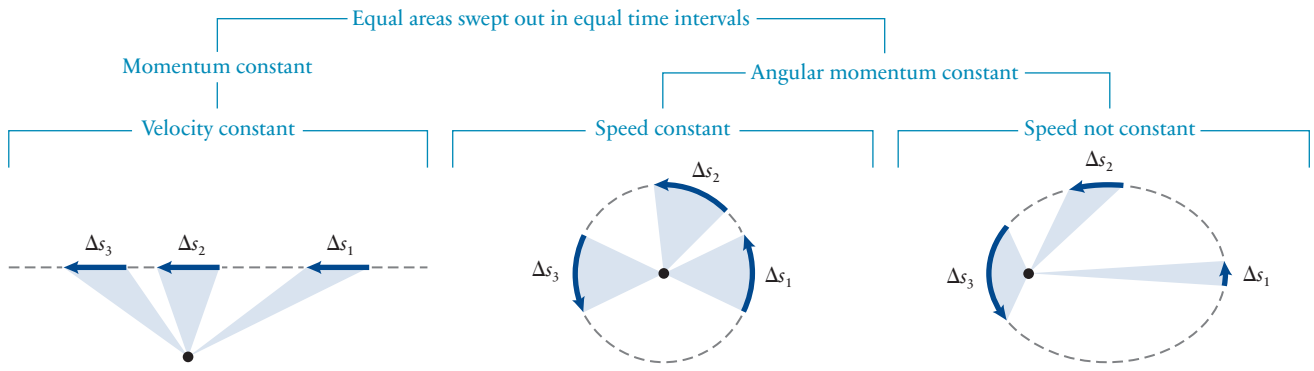
(*a*) Object moving with constant momentum along straight line

(*b*) Object moving with constant angular momentum along curve

circular orbit is simple: If the angular momentum is constant, then the object's speed must be constant (that is, we are dealing with circular motion at constant speed).



To understand the meaning for any other type of orbit, we must first introduce a geometric interpretation of angular momentum. Consider first the particle moving along a straight line illustrated in **Figure 13.11*a***. As we saw in Section 12.8 the angular momentum of any moving particle about the origin can be written as $\vec{L} = \vec{r} \times \vec{p}$, where $\vec{r}$ is the position of the particle (Eq. 12.43). In a time interval dt, the position vector $\vec{r}$ sweeps out the area of the shaded triangle in Figure 13.11*a*. As we saw in Section 12.8, the magnitude of the vector product of two vectors is equal to the area of the parallelogram defined by them. So $|\vec{r} \times d\vec{r}\,|$ is the area of the dashed parallelogram in Figure 13.11*a*—twice the area dA of the shaded triangle. Because the particle's displacement can be written as $d\vec{r} = \vec{v}\,dt$, we have $dA = \frac{1}{2}|\vec{r} \times \vec{v}|dt = \frac{1}{2}L/m\,dt$. The rate at which the area A is swept out by the position vector is thus $dA/dt = \frac{1}{2}L/m$. In words:

> **The angular momentum of a particle about an origin is proportional to the rate at which area is swept out by the particle's position vector.**

So, when the angular momentum of a particle is constant, the rate dA/dt is also constant. Figure 13.11*b* shows the motion of an object along a curved trajectory. In two equal time intervals dt, the position vector sweeps out areas dA_1 and dA_2. If the angular momentum of the object about O is constant, then $dA_1 = dA_2$. The motion caused by a central force directed to the origin is such that the radius vector from the origin sweeps out equal areas in equal time intervals *regardless of the shape of the trajectory*. In the early 17th century, before Newton formulated the law of gravity and long before the concept of angular momentum was introduced, Johannes Kepler had already deduced from astronomical observations that the straight line from the Sun to each planet sweeps out equal areas in equal time intervals. (See the box "Kepler's laws of planetary motion.")

CONCEPTS

Figure 13.12 Three forms of motion with constant angular momentum.

(*a*) Motion at constant velocity along straight line

(*b*) Motion at constant speed along circular path

(*c*) Motion about one focus of an ellipse in response to central force

Figure 13.12 shows three types of motion with constant angular momentum: motion at constant speed along a straight line (no force; constant velocity), circular motion at constant speed (central force; constant speed), and elliptical motion (central force; constant rate of area swept). For the third it is not immediately obvious that the angular momentum is constant: Neither the velocity direction nor the speed of the moving object is constant. For all three types of motion, however, the position vector sweeps out the same area in equal time intervals. To do so an object in elliptical motion (Figure 13.12*c*) must move fastest when it is closest to the object it is orbiting and slowest when it is the farthest away, in agreement with the answer to Checkpoint 13.6, part *b*.

EXAMPLE 13.2 Pluto

Of all the objects in Table 13.1, Pluto has the orbit with the greatest eccentricity. (*a*) What is the ratio of the orbit's semiminor axis b to its semimajor axis a? (*b*) What is the ratio of Pluto's speed at perihelion to its speed at aphelion?

❶ **GETTING STARTED** I begin by making a sketch of Pluto's orbit, using the Sun as one focus (**Figure 13.13** on the next page). From Figure 13.8 I know that the orbit is very nearly circular but the Sun is off-center, making the orbit slightly elliptical. I mark the perihelion (shortest Sun-orbit distance) and aphelion (longest Sun-orbit distance) and show velocity vectors at those locations because I am asked about speeds there. In the ellipse as I have oriented it, with the line defining the foci horizontal, the semiminor axis b extends from the

(Continued)

Kepler's laws of planetary motion

The German mathematician and astronomer Johannes Kepler devoted much of his life to analyzing celestial motion data collected by Tycho Brahe. Kepler discovered three laws of planetary motion.

Kepler's first law describes the shape of the planetary orbits:

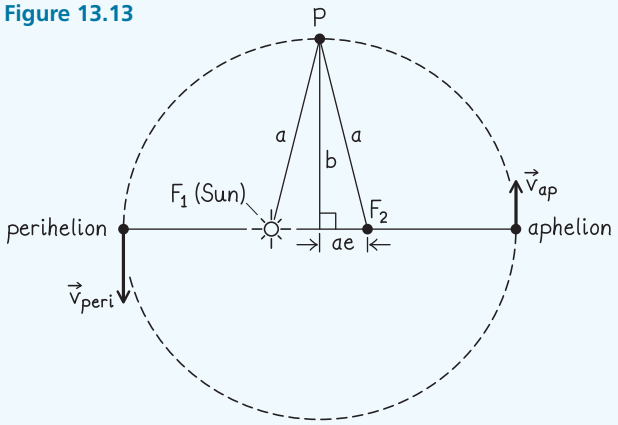
> **All planets move in elliptical orbits with the Sun at one focus.**

Although the deviation from circular orbits is small, this statement was a radical departure from the accepted wisdom, dating back to Plato, that the planets, being heavenly bodies, were perfect and therefore could move in only perfect circles or combinations of circles.

Kepler's second law reveals that, even if planets are not in circular motion at constant speed, their motions obey the following requirement:

> **The straight line from any planet to the Sun sweeps out equal areas in equal time intervals.**

Kepler's third law relates the planetary orbits to one another:



> **The squares of the periods of the planets are proportional to the cubes of the semimajor axes of their orbits around the Sun.**

Kepler discovered this third law by painstakingly examining, over a period of many years, countless combinations of planetary data.

In keeping with Aristotelian notions, Kepler believed that a force was necessary to drive the planets along their orbits, not to keep them in orbit. Consequently, Kepler was unable to provide a correct explanation for these three laws. It was not until Newton that the single unifying reason for these laws was established. As we've seen, Kepler's three laws follow directly from the law of gravity: The first and third laws are a consequence of the $1/r^2$ dependence, and the second law reflects the central nature of the gravitational force.

CONCEPTS

Figure 13.13

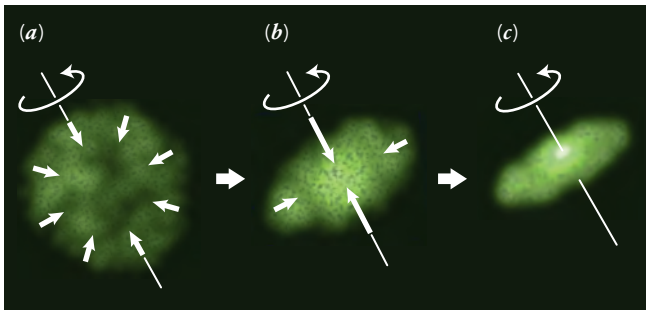
center of the major axis to point P at the top of the ellipse. The ratio of the semimajor and semiminor axes can be obtained from either right triangle in Figure 13.13. Because the sum of the distances from any point on an ellipse to the two foci is $2a$ (see Figure 13.7), I know that $\overline{F_1P} = \overline{F_2P} = a$.

2 DEVISE PLAN For part *a*, I can use the Pythagorean theorem and the values in Table 13.1 to calculate the ratio b/a. For part *b* I know that the planet's angular momentum about the Sun must be constant because the force exerted by the Sun on Pluto is a central force. I can therefore calculate the angular momentum at perihelion and at aphelion and set the two equal to obtain the ratio $v_{\text{peri}}/v_{\text{ap}}$.

3 EXECUTE PLAN (*a*) Applying the Pythagorean theorem to the right triangle containing F_2 gives $b = +\sqrt{a^2 - (ae)^2} = a\sqrt{1 - e^2}$. Using the value of e from Table 13.1, I get $b/a = +\sqrt{1 - (0.25)^2} = 0.97$. ✔

(*b*) At perihelion, the Sun-Pluto distance is $(a - ae)$, and the angular momentum is $L_{\text{peri}} = m(a - ae)v_{\text{peri}} = ma(1 - e)v_{\text{peri}}$ (Eq. 11.36); at aphelion, $L_{\text{ap}} = ma(1 + e)v_{\text{ap}}$. Because $L_{\text{peri}} = L_{\text{ap}}$, I get

$$ma(1 - e)v_{\text{peri}} = ma(1 + e)v_{\text{ap}},$$



so

$$\frac{v_{\text{peri}}}{v_{\text{ap}}} = \frac{1 + e}{1 - e} = \frac{1 + 0.25}{1 - 0.25} = 1.7. \checkmark$$

4 EVALUATE RESULT The semiminor and semimajor axes are equal to within 3%, which agrees with what is shown in Figure 13.8. That v_{peri} is greater than v_{ap} agrees with my answer to Checkpoint 13.6, part *b*.

Conservation of angular momentum is also responsible for the flat, disk shape of most galaxies and of our solar system. **Figure 13.14** illustrates the gravitational contraction of a slowly rotating cloud of interstellar gas and dust. Because the cloud's rotational inertia decreases as it contracts, its rate of rotation must increase, just as a skater spins faster with her arms pulled in. In the plane perpendicular to the rotation axis, part of the gravitational force directed toward the center of the cloud goes into providing the centripetal acceleration. Regions near this plane therefore undergo less contraction than do regions along the axis. This differential contraction results in the characteristic disk shape of many galaxies.

Figure 13.14 (*a*) Gravitational contraction of a slowly rotating cloud of interstellar gas and dust. (*b*) Conservation of angular momentum requires the rotational velocity to increase as the cloud contracts and its rotational inertia decreases. (*c*) Contraction is less efficient in the plane perpendicular to the rotation axis because part of the gravitational interaction goes into supplying the centripetal acceleration.

13.3 Weight

The law of gravity states that the force of gravity depends on location. **Figure 13.15** shows astronauts orbiting Earth at an altitude of about 400 km. Are they floating "weightlessly" inside their spacecraft because the force of gravity at their location has been reduced to a negligible value? The calculation is easy and worth doing, as the next checkpoint shows.

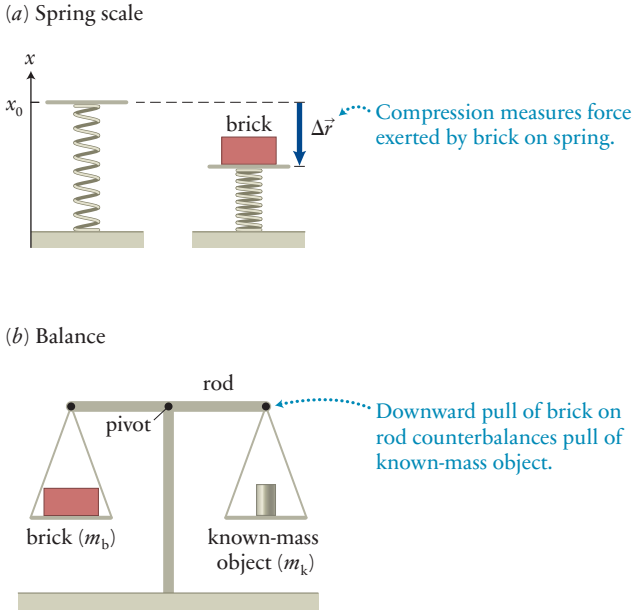
13.7 The space shuttle typically orbits Earth at an altitude of about 300 km. (*a*) By what factor is the shuttle's distance to the center of Earth increased over that of an object on the ground? (*b*) The gravitational force exerted by Earth on an object in the orbiting shuttle is how much smaller than the gravitational force exerted by Earth on the same object when it is sitting on the ground? (*c*) What is the acceleration due to gravity at an altitude of about 300 km? (*d*) While in orbit, the shuttle's engines are off. Why doesn't the shuttle fall to Earth?

After answering this checkpoint, you may be wondering in what sense objects inside the space shuttle are "weightless." To resolve this issue, we must define what we mean by *weight*.

Figure 13.15 Astronauts Shane Kimbrough and Sandra Magnus float "weightlessly" in Space Shuttle Endeavour during mission STS-126.

CONCEPTS

Figure 13.16 Two methods for weighing a brick.



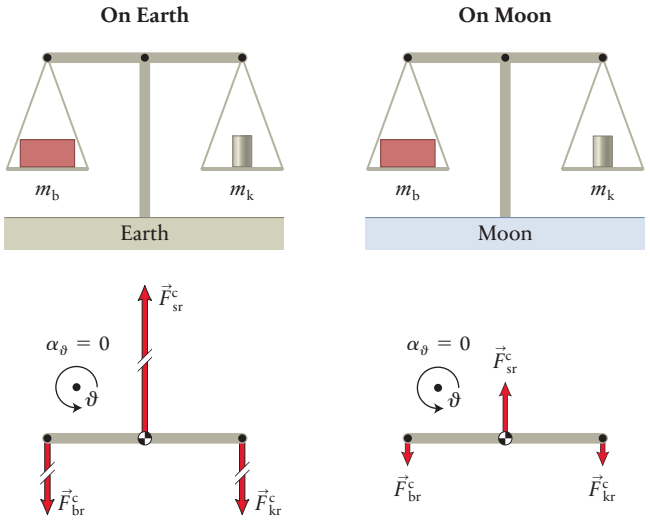


Figure 13.16 illustrates two types of devices used for weighing objects. When a load is put on a **spring scale,** the load either compresses or stretches a spring inside the scale (Figure 13.16*a*). The change in the spring's length is proportional to the force exerted on it by the load: $F^c_{ls\,x} = k(x - x_0)$ (Eq. 8.18). The deformation of the spring therefore provides a measure of the downward force exerted on it by the load. When you stand on a bathroom scale, for example, the downward force exerted by your body on the scale compresses a spring inside it, which, in turn, rotates a dial, and you read your weight off the dial. The rotation of the dial is proportional to the force exerted by your body on the scale. (The scale was calibrated at the factory by putting objects of known mass on it.)

13.8 A 1.0-kg brick is placed on a spring scale. (*a*) What is the magnitude of the force exerted by Earth on the brick? (*b*) What is the magnitude of the force exerted by the brick on the scale? (*c*) How many steps are required to answer part *b*? (*d*) Does the spring scale measure the pull of gravity on the brick?

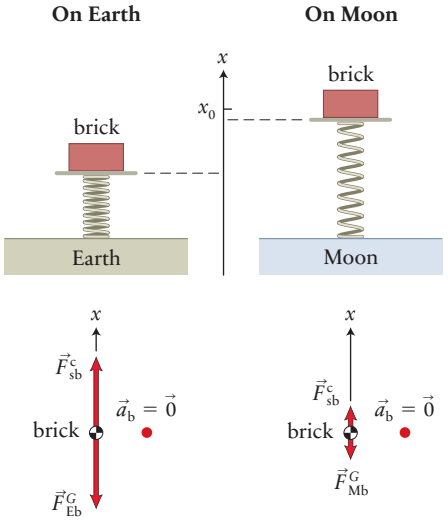
Another type of weighing device, the **balance,** illustrated in Figure 13.16*b*, works as follows. A brick whose mass m_b is to be determined is suspended from one end of a rod pivoted about its center, and objects of known masses are suspended from the other end until the rod is in mechanical equilibrium. In mechanical equilibrium, the downward forces exerted by the loads on the two ends of the rod are equal, and so m_b must be equal to the sum m_k of the known masses.

Don't both devices measure the same thing? You may be surprised to learn that the answer to this question is *no*. To see why, suppose we repeat the experiments

Figure 13.17 Using a balance at Earth's surface and on the Moon. If the rod is balanced on Earth, the same objects balance the rod on the Moon.

illustrated in Figure 13.16 on the surface of the Moon. The gravitational force exerted by the Moon on an object sitting on the lunar surface is about six times smaller than the gravitational force exerted by Earth on the same object sitting on Earth's surface. If you were carrying a heavy load on the Moon, you would discover that the force needed to support it is less than on Earth; on the Moon the load feels a lot lighter. As the extended free-body diagrams in **Figure 13.17** show, however, the smaller gravitational pull of the Moon does not affect the mechanical equilibrium of the balance: The downward pull diminishes on *both* sides, and so the rod remains in mechanical equilibrium. With the balance, we still obtain $m_b = m_k$, just as we do on Earth.

The reading of the spring scale on the Moon, however, is not the same as it is on Earth. Because of the weaker pull of gravity on the Moon, the deformation of the spring is smaller, as shown in **Figure 13.18** on the next page. Spring scale readings on the Moon are about six times smaller than on Earth. So the spring scale tells us that the load weighs less on the Moon than on Earth, while the balance tells us that it weighs the same. This difference arises because:



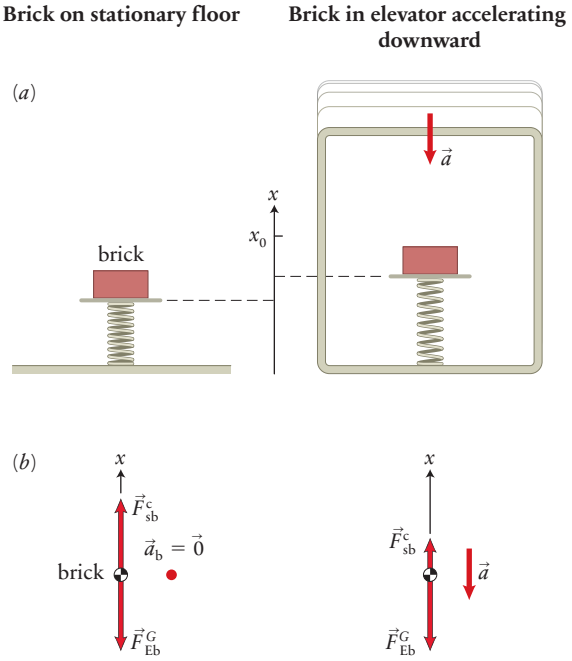
A spring scale measures the downward force exerted on it by its load, but a balance compares gravitational forces and measures mass.

The result obtained with a spring scale depends on the strength of the gravitational pull on the load; the result obtained with a balance does not depend on the strength of the gravitational pull.*

*Many modern weighing devices are called "balances" even though in reality they operate like spring scales. Typically, these devices employ a pivoted rod, but instead of comparing gravitational forces, one end of the rod is connected to a spring or other mechanism for generating a calibrated force.

CONCEPTS

Figure 13.18 Free-body diagrams for a brick on a spring scale on the surface of Earth and the Moon. Because of the smaller gravitational attraction by the Moon, the spring's compression on the Moon is less than it is on Earth.



13.9 A 1.0-kg brick is placed on a spring scale inside the space shuttle orbiting Earth at 300 km altitude. (*a*) What is the magnitude of the force exerted by Earth on the brick? (*b*) What is the magnitude of the force exerted by the brick on the spring scale? (Hint: See the astronauts in Figure 13.15.) (*c*) Does the spring scale measure the pull of gravity on the brick? (*d*) Why is your answer different from your answer to Checkpoint 13.8, part *d*?

The answers to this checkpoint show that the reading of a spring scale depends not only on the gravitational pull on its load but also on the acceleration of the scale. To see this point more clearly, consider the situation shown in **Figure 13.19***a*. Two bricks of identical mass m are placed on two identical spring scales, one on solid ground and the other in an elevator that is accelerating downward. Figure 13.19*b* shows the free-body diagrams for both bricks. Because the brick in the elevator has a downward acceleration, we know that the vector sum of the forces exerted on it has to be nonzero and directed downward. The downward force of gravity has not changed, however. Consequently, the upward force exerted by the scale on the brick must be *smaller* than the magnitude of the downward force of gravity acting on it. Because the force exerted by the scale on the brick and the force exerted by the brick on the scale form an interaction pair, we conclude that the force exerted by the brick on the scale in the elevator is smaller than that exerted by the identical brick on the stationary spring scale. The spring scale in the elevator therefore gives a lower reading than the stationary scale.

If you are surprised that the result of weighing an object with a spring scale depends on acceleration, try the following experiment. Put an object in the palm of your hand with your arm stretched out in front of you,

Figure 13.19 A spring scale holding a brick gives a different reading when it is stationary and when it is in an elevator accelerating downward. Because of the acceleration of the elevator, $\Delta x_{elev} < \Delta x_{stat}$.

then rapidly move your hand downward. While you accelerate your hand downward, you can feel that the object presses less on your hand than it does when you hold your hand still. In other words, while your hand accelerates downward, the object in it feels lighter—it feels as though it "weighs" less.*

13.10 (*a*) An object is placed on a spring scale in an elevator moving upward at a constant speed. Is the reading of the scale greater than, smaller than, or the same as the reading obtained in a stationary elevator? (*b*) How does the reading of a scale in an elevator that has upward acceleration $a = 0.5g$ compare with the reading obtained in a stationary elevator? (*c*) What if the elevator has downward acceleration $a = g$?

As this checkpoint shows, objects in an elevator that is in free fall produce a zero spring scale reading. No force is necessary to support them: They, too, fall freely along with the elevator. Inside a freely falling elevator, a spring scale under your feet—falling away underneath you, together with the elevator and everything inside it—reads zero. If you were to hold a briefcase in the freely falling elevator, you would discover that the briefcase does not need to be supported by your hand because the force of gravity gives it the same

*You can also try this by accelerating your hand upward, in which case the object feels heavier. The effect, however, is less pronounced because it is more difficult to accelerate your arm upward. In the downward direction, gravity and your muscles work together to provide the acceleration; in the upward direction, your muscles have to not only accelerate your arm but also counteract the effect of gravity.

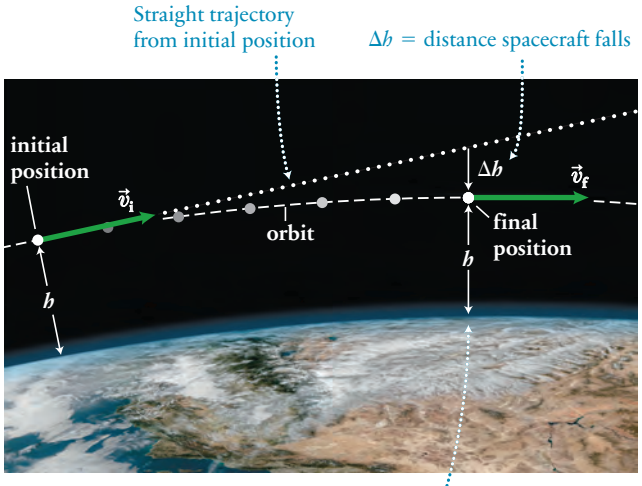
CONCEPTS

downward acceleration g as you. The briefcase feels weightless—you could even let go and the briefcase would ue to hover next to you.

Any object in free fall—that is, any object subject to only a force of gravity—experiences weightlessness.

If this appears odd, consider once again the astronauts in orbit in Figure 13.15. The only force exerted on them is the force of gravity, and so they *are* in free fall! This free fall is precisely what makes them weightless. Because of their large speed and the curvature of Earth, however, they do not come closer to the ground. As they fall, the ground below them recedes at the same speed as they fall (**Figure 13.20**).

13.11 (*a*) How far does the space shuttle in Figure 13.20, 300 km above Earth, fall in 1.0 s? (*b*) If the radius of Earth is 6400 km, what is the shuttle's speed?



You don't need to be an astronaut to experience weightlessness. When you jump off a chair, you are momentarily weightless; during your short free fall, an object in the palm of your hand hovers weightlessly above your hand. A plane flying across a large parabolic arc may be in a controlled free fall for short time intervals. As shown in **Figure 13.21**, people inside such an airplane float weightlessly, just as astronauts in orbit do.

13.12 Planes can be put (safely) into free fall for periods up to 40 s. (*a*) If the plane shown in Figure 13.21 was flying horizontally before being put into free fall, how much altitude does it lose in those 40 s? (*b*) What is the plane's final vertical speed of descent? (*c*) At the instant shown, is the vertical component of the plane's velocity directed upward, directed downward, or zero?

The discussion in this section shows that our notion of *weight* corresponds most closely to the reading of a spring scale: The perceived "heaviness" of an object depends, as does the reading on the scale, not only on the pull of gravity on the object but also on its acceleration. The "weightless" astronauts in the space shuttle would indeed register a zero scale reading, even though the pull of gravity on them is almost identical to the pull at Earth's surface.

Because spring scale readings depend on acceleration, however, weight is often defined as the force of gravity exerted *on* an object. Spring scale readings are then called *apparent* or *effective weight*. With this definition, the astronauts in Figure 13.15 and the people in Figure 13.21 are not weightless because the force of gravity on them (their "weight") is the same as it is on Earth's surface, and so they must be called *apparently weightless*. To avoid all these difficulties and the conflict between our intuitive notion of weight (spring scale reading) and the common definition of weight (force of gravity), we therefore avoid using the word *weight* in this book. Instead we shall use the more precise "force of gravity" to refer to the downward pull of gravity on an object and "scale reading" to refer to the force exerted by an object on a spring scale.

Figure 13.20 As a spacecraft orbits Earth a distance h above the ground, it falls a distance Δh. Because the craft moves so fast in a direction tangential to the (curved) ground, the ground "falls away" at the same rate, and the distance between the craft and the ground remains constant.

Height h of orbit remains constant because of distance Δh spacecraft falls.

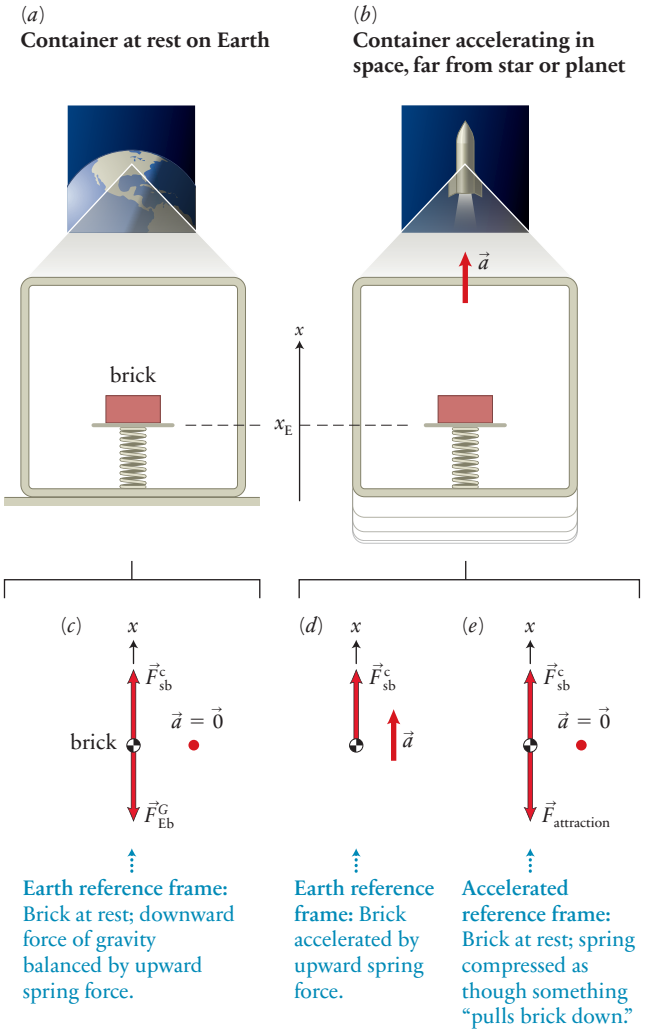
13.13 Consider an airplane flying at a constant speed of 900 km/h, 10 km above the ground. (*a*) What is the plane's downward acceleration? (*b*) Draw a free-body diagram for the airplane. (*c*) Why don't people in the airplane feel weightless as astronauts do traveling 290 km higher up?

Figure 13.21 If an airplane briefly follows a parabolic path such that it has a downward acceleration g, the airplane and the people inside it are in free fall. In this picture, astronaut candidates aboard a KC-135 Stratotanker briefly experience weightlessness as they and the plane are in a short free fall.

CONCEPTS

13.4 Principle of equivalence

Let us return to the remarkable equality of mass and inertia. The simplest possible test of this equality is obtained by dropping two objects that have different inertias and are made of different materials and measuring their accelerations. As Galileo discovered, *all* objects fall with the same acceleration g. It is true that Earth pulls twice as hard on an object that has twice the mass, but because this object also has twice the inertia, it doesn't accelerate any faster. The equality of mass and inertia has been tested experimentally to one part in 10^{12}.



The equality of mass and inertia may seem obvious because we are so accustomed to the fact that heavier objects not only take more effort to support against gravity but also take more effort to be set in motion. Intuitively, both properties simply go by the amount of matter in the object. Yet this equality suggests a much deeper connection between gravity and acceleration.

In Section 13.3 we encountered another manifestation of this equivalence between gravity and inertia: The reading on a spring scale depends not only on the gravitational pull on the load but also on the acceleration of the scale. We can change the reading of the scale—our notion of weight—simply by accelerating the scale. This raises an interesting question: Can we design an experiment that distinguishes between gravity and an accelerated reference frame?

Consider a brick placed on a spring scale inside a container at rest on the surface of Earth, as illustrated in **Figure 13.22*a***. Because of the gravitational attraction exerted by Earth on the brick, the brick compresses the spring to a scale reading x_E. To an observer in the Earth reference frame the brick is at rest, and so the upward force exerted by the scale is equal in magnitude to the downward force exerted by Earth (see Figure 13.22*c*). Now picture the same arrangement in space, far away from any planet or star, where the influence of gravity is negligible and so we can say that $g = 0$. Suppose the container is towed by a spaceship; if the spaceship fires its rockets, the container accelerates, as illustrated in Figure 13.22*b*. Objects inside the container no longer float weightlessly, but being dragged along by the container, they rest against the bottom of the container. If the brick is placed on the scale, the scale registers a reading proportional to the force exerted by the spring on the brick. This force is required to give the brick the same acceleration $\vec{a}$ as the container. From the point of view of an observer in the Earth reference frame, the brick has an upward acceleration $\vec{a}$ (see Figure 13.22*d*).

If the rockets are fired such that $a = g$, could you, from inside the container, tell the difference between being accelerated in space and being on Earth? To you, the scale and the scale reading appear just as they do on Earth. An object released from your hand falls with an acceleration g, just as it does on Earth. From inside the container, with both of your feet solidly on the floor, everything looks and feels just as it does on Earth—all objects appear to be attracted to the container floor.

Figure 13.22 If you observe a brick compressing a spring scale in an enclosed container, you cannot tell whether the compression is due to a gravitational interaction or to acceleration of the container.

Having observed all this, you draw the free-body diagram shown in Figure 13.22*e*: From your point of view, the brick is at rest, and so the vector sum of the forces exerted on it must be zero. So, in addition to an upward force exerted by the compressed spring on the brick, you draw a downward force, equal in magnitude to that of the upward force. To you, it appears as if this force is due to a downward attraction experienced by all objects inside the container. Without peeking outside, you cannot determine whether this attraction is present because underneath the container there is a planet or because the container is accelerating upward in space.

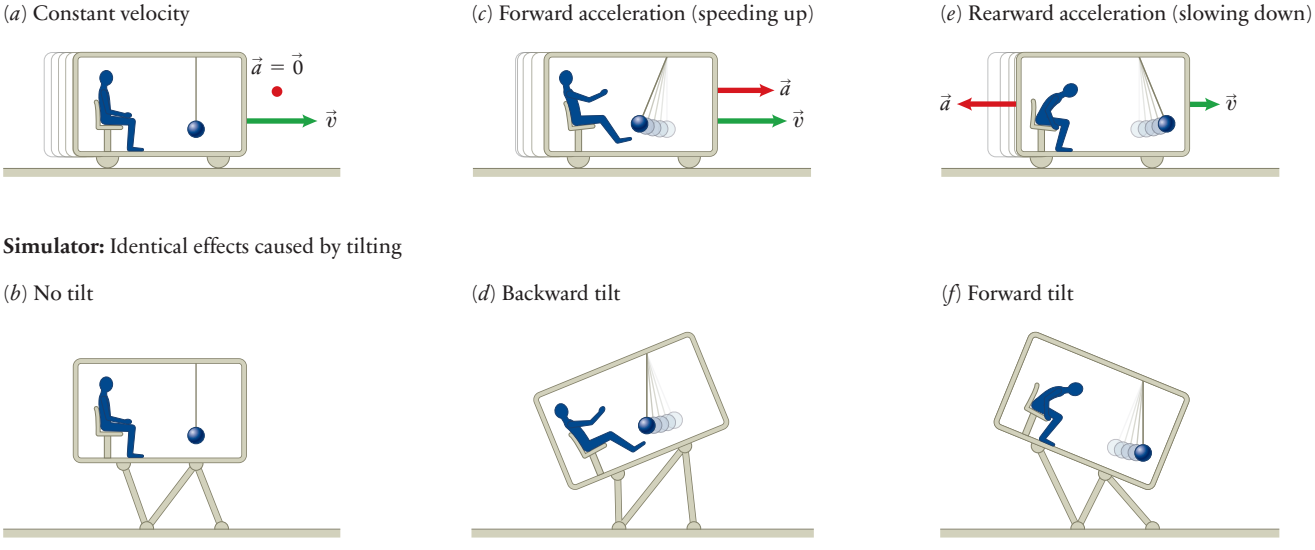
Notice that the fictitious attractive force experienced by objects inside the container is no less mysterious than the force of gravity. Both forces have the same effect: Objects are pulled toward the bottom of the container according to their mass or inertia (the distinction has now disappeared). Although the gravitational force

CONCEPTS

A flight simulator for the Sukhoi Superjet 100.

is more familiar, and although Newton's law of gravity describes its behavior, we really have no idea how gravity "works." The conclusion is thus:

> **One cannot distinguish locally between the effects of a constant gravitational acceleration of magnitude g and the effects of an acceleration of the reference frame of magnitude $a = g$.**



This statement, called the **principle of equivalence,** is the starting point for the theory of general relativity developed by Albert Einstein in the early 1900s. The word *locally* is necessary because on a large scale, the $1/r^2$ dependence of the gravitational force becomes apparent: For a very tall container in Figure 13.22, the gravitational acceleration at the top of the container would be smaller than at the bottom; for a very wide container, it would become noticeable that objects are falling not parallel to one another but toward a single point—the attracting object's center. In the theory of general relativity, the effects of gravity are explained in an entirely geometric way. Gravity and acceleration are one.

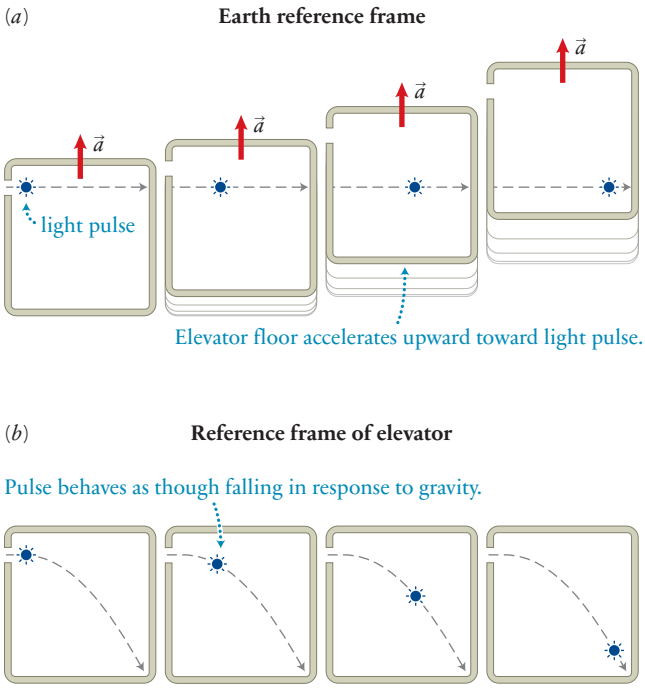
On a practical note, our inability to distinguish between gravity and acceleration is exploited in aircraft flight simulators and motion simulators in the amusement industry. These devices are programmed to tilt in concert with a film simulating a ride in a vehicle, airplane, or spaceship. The effect is a startlingly realistic sensation of motion. The principle of operation is shown in Figure 13.23. Suppose you are in a closed container, with a ball suspended from the ceiling. If the container rolls at constant speed along a track, as in Figure 13.23*a*, you cannot *feel* the motion and the string hangs vertically, although sounds from the wheels and little bumps in the track might give away that the container is in motion. The law of inertia (see Section 6.2) tells us, however, that you cannot determine the difference between moving at constant speed and sitting at rest. So, with the container on a stationary base, as in Figure 13.23*b*, if the container shakes a bit to simulate bumps and you hear the same sounds and see a movie of a landscape that flows by at constant speed, the illusion of moving at constant speed is complete.

Now suppose the container speeds up, as in Figure 13.23*c*. The chair presses against your back to accelerate you along with the container, and as a result you feel pushed backward against the chair. As Figure 13.23*d* shows, the same effect can be obtained by tilting a stationary container backward (together with appropriate sounds and visual clues). In both cases, also, the ball suspended from the ceiling tilts toward you, and objects don't fall straight to the floor. From inside the container, you cannot tell whether these things happen because the container accelerates or because gravity is in a different direction.

CONCEPTS

Figure 13.23 The principle of equivalence states that an observer inside a closed container cannot distinguish between motion at constant speed and rest, between speeding up and tilting backward, or between slowing down and tilting forward.

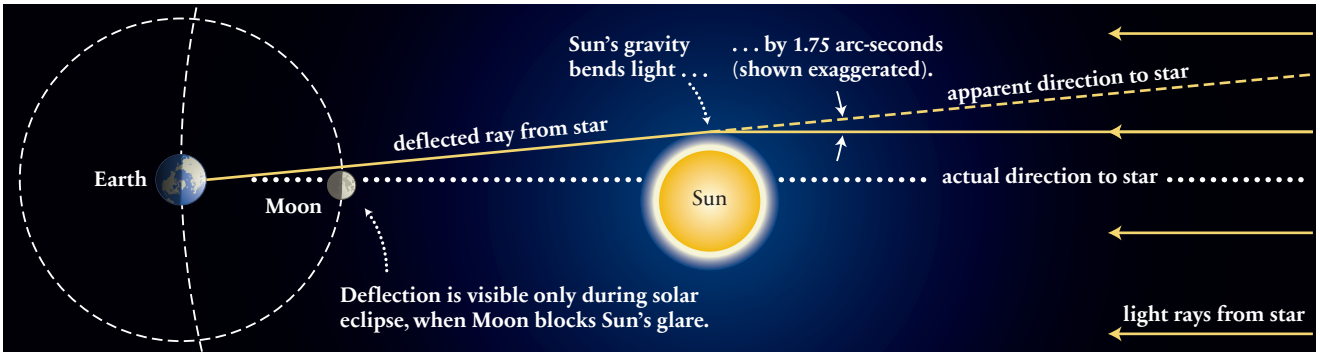
To simulate slowing down (see Figure 13.23*e*), the container needs to be tilted forward (see Figure 13.23*f*). The result is that you feel pushed forward, as in a sharply braking car, and the ball tilts away from you. Again you cannot tell whether the container is slowing down or gravity is pulling in a different direction.



13.14 How should the simulator in Figure 13.23 be tilted to simulate a right turn?

The simulator example may give you the impression that the principle of equivalence has more to do with our senses than with the properties of the universe. This is not so, however. Because anything that moves along a straight line in an inertial reference frame must move along a curved path in an accelerated reference frame, the principle of equivalence tells us that *anything* that moves near an object that has mass must move along a curved path. **Figure 13.24** shows that a light pulse that travels along a straight line in the Earth reference frame but then enters an accelerating elevator must move along a curved path as viewed from inside the elevator. This effect is purely kinematic, and so given the equivalence between gravity and acceleration, the bending should also occur if the elevator, instead of accelerating upward, were placed on top of an object with a large mass.

13.15 Light travels at approximately 3.0×10^8 m/s. (*a*) How long does it take for a light pulse to cross an elevator 2.0 m wide? (*b*) How great an acceleration is necessary to make the pulse deviate from a straight-line path by 1.0 mm? Is it likely that this effect can be observed? (*c*) If light is bent by the gravitational pull of an object, light should "fall" when traveling parallel to the surface of Earth. How far does a beam of light travel in 0.0010 s, and how much does it fall over that distance? Is it likely that this effect can be observed?



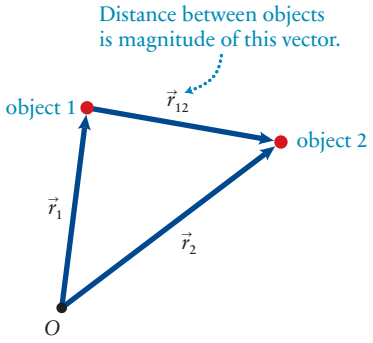
Although the calculations in this checkpoint show that detection of the gravitational bending of light is difficult, the effect was observed within a few years of its prediction in 1915. Because of the large mass of the Sun, a ray that passes close to the Sun should undergo a deflection. Although it is normally impossible for us earthlings to see any stars close to the Sun, the light from the Sun is blocked by the Moon during a solar eclipse (**Figure 13.25**). By comparing a picture of stars near the Sun taken during an eclipse with a picture of the same stars taken when the Sun is far away from them (in other words, at night), it is possible to observe the bending of light caused by the Sun's gravitational attraction. The measured values of such deflections are in excellent agreement with the theoretical values.

Figure 13.24 A light pulse traverses an accelerating container.

13.16 (*a*) What would the scale reading be if the container in Figure 13.22*b* were traveling at constant speed instead of accelerating? (*b*) Describe the path of the light pulse in the reference frame of the elevator in Figure 13.24*b* if the elevator were traveling at constant speed.

Figure 13.25 When the Sun passes close to our line of sight to a star, the Sun's gravity bends the star's light, slightly shifting the star's apparent location in the sky. This effect is visible only during a solar eclipse, when the Moon blocks the Sun's glare. Diagram not to scale.

CONCEPTS



Self-quiz

1. Determine the ratio of Earth's gravitational force exerted on a 1.0-kg object at the following positions to that at sea level: (*i*) the top of Mt. Everest, altitude 8848 m; (*ii*) a shuttle orbiting at 200 km; (*iii*) the orbit of the Moon. Is the 1.0-kg object weightless in any of these circumstances?
2. The orbital period of Jupiter around the Sun is 11.86 times that of Earth. What is the ratio of their distances to the Sun?
3. If the speed of a planet in its orbit around the Sun changes, how can the planet's angular momentum be constant?
4. A brick of unknown mass is placed on a spring scale. When in equilibrium, the scale reads 13.2 N. Which of the following statements is/are true? (*i*) Earth always exerts a gravitational force of 13.2 N on the brick. (*ii*) The normal force the scale exerts on the brick is 13.2 N. (*iii*) The brick has an inertia of 1.32 kg.
5. Draw a free-body diagram of an individual experiencing weightlessness in an elevator. What must the elevator's acceleration be for this to occur?
6. If you were to travel in a vertical circle, at what point in the circle would you be most likely to experience weightlessness?

Answers

1. The gravitational force is proportional to the inverse square of the distance between Earth and the object. For each case, we have $F_{\text{pos}}/F_{\text{sea level}} = r_{\text{sea level}}^2/r_{\text{pos}}^2$, where $r_{\text{sea level}} = 6.378 \times 10^6$ m (Earth's radius) and r_{pos} is the distance between the position in question and Earth's center. (*i*) The distance to Earth's center is the sum of Earth's radius and the altitude of Mt. Everest: $r_{\text{pos}} = (6.378 \times 10^6\ \text{m}) + (8848\ \text{m}) = 6.387 \times 10^6$ m; $F_{\text{pos}}/F_{\text{sea level}} = 0.997$. (*ii*) $r_{\text{pos}} = (6.378 \times 10^6\ \text{m}) + (200{,}000\ \text{m}) = 6.578 \times 10^6$ m; $F_{\text{pos}}/F_{\text{sea level}} = 0.940$. (*iii*) The distance to Earth's center is the radius of the Moon's orbit. Given that the Moon's orbit is nearly circular, I use the value of the semimajor axis in Table 13.1: $r_{\text{pos}} = 3.84 \times 10^8$ m; $F_{\text{pos}}/F_{\text{sea level}} = 0.000276$. The object is never weightless because, in each case, it experiences a gravitational force and, in all but the last case, the magnitude of this force is very close to the magnitude at sea level on Earth.
2. The period squared is proportional to the cube of the orbital radius. Therefore, the square of the ratio of the periods ($11.86^2 = 141$) is equal to the cube of the ratio of the orbital radii. The ratio of the radii is then $141^{1/3} = 5.2$. Check this value against the data in Table 13.1.
3. If the angular momentum is constant but the speed changes, the rotational inertia must change. When a planet's speed increases, it must move nearer the object it orbits (or its inertia must decrease) to keep the angular momentum constant. Conversely, when a planet's speed decreases, it must move away from the object it orbits (or its inertia must increase).
4. Only statement (*ii*) is true. The scale reading may change from location to location, and the inertia of the brick is 1.32 kg only when the gravitational acceleration at the specific location is 10 m/s^2.
5. If a person experiences weightlessness, the only force acting on her or him is the gravitational force. Contact with the elevator floor is not necessary. If the person is in free fall, the elevator must also be in free fall. The free-body diagram consists of just one force vector, $\vec{F}_{\text{Ep}}^{G}$ downward.
6. To experience weightlessness, the only force acting on you is the gravitational force exerted by Earth, which points downward. This downward force provides the centripetal acceleration needed for traveling in a circle. The most likely position from which the center of the circle is downward is the top of the circle.

Figure 13.26 The distance between two objects whose positions are given by the vectors $\vec{r}_1$ and $\vec{r}_2$ is equal to the magnitude of the vector $\vec{r}_2 - \vec{r}_1$.

13.5 Gravitational constant

As we saw in Section 13.1, Newton's **law of gravity** states that the gravitational force exerted by a object of mass m_1 on an object of mass m_2 is an attractive, central force that is proportional to the product of the masses and inversely proportional to the square of the distance between them. If the positions of the two objects are given by the vectors $\vec{r}_1$ and $\vec{r}_2$, then the distance between them is $r_{12} = |\vec{r}_2 - \vec{r}_1|$, as shown in **Figure 13.26**. We can thus write the magnitude of the gravitational force as

$$F_{12}^G = G\frac{m_1 m_2}{r_{12}^2}, \tag{13.1}$$

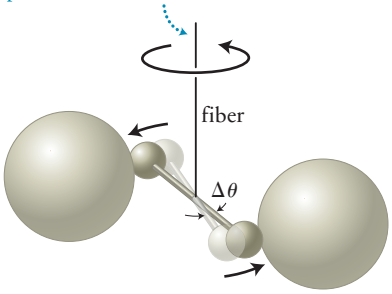
where the proportionality constant G is called the **gravitational constant.** The force is attractive and directed along the straight line joining the objects.

What is the relationship between Eq. 13.1 and the magnitude mg of the gravitational force near Earth's surface? To answer this question, let object 1 in Eq. 13.1 be Earth with mass m_E and let object 2 be an arbitrary object of mass m_o near Earth's surface:

$$F_{Eo}^G = G\frac{m_E m_o}{r_{Eo}^2}. \tag{13.2}$$

For an object a distance h above the ground, the distance between the object and Earth's center is $r_{Eo} = R_E + h$, where R_E is the radius of Earth. Near the ground, $h \ll R_E$, $r_{Eo} \approx R_E$, and Eq. 13.2 becomes

$$F_{Eo}^G = \frac{Gm_E m_o}{r_{Eo}^2} \approx G\frac{m_E m_o}{R_E^2} = m_o\left(\frac{Gm_E}{R_E^2}\right) \quad \text{(near Earth's surface).} \tag{13.3}$$



The term in parentheses represents the acceleration of the object due to the force F_{Eo}^G. Knowing from our study of the gravitational force that $F_{Eo}^G = m_o g$, we see that

$$g = \frac{Gm_E}{R_E^2} \quad \text{(near Earth's surface).} \tag{13.4}$$

Because G, m_E, and R_E are all constant, the law of gravity does indeed give a constant acceleration near the surface of Earth.

13.17 For an object released from a height $h \approx R_E$ above the ground, does the acceleration due to gravity decrease, increase, or stay the same as the object falls to Earth?

Figure 13.27 Schematic representation of Cavendish's experimental setup to determine the gravitational constant. The entire setup is enclosed in a box to shield it from air currents.

Working in about 1677, Newton knew the radius of Earth but not its mass, and so he could get only a rough value of G by estimating m_E (as you did in Checkpoint 1.16). The magnitude of G was determined experimentally by Henry Cavendish in 1798. The basic principle of Cavendish's measurement is shown in **Figure 13.27**. Two small lead spheres connected by a light rod are suspended from a long thin fiber. When two large lead spheres are placed near the small spheres, the gravitational attraction between the large and small spheres causes the rod to rotate, thus twisting the fiber. Equilibrium is reached when the torque caused by the gravitational forces is equal in magnitude to the opposing torque caused by the twisted fiber. By calibrating the degree to which known forces twist the fiber, Cavendish was able to measure the gravitational force between the lead spheres. Knowing this force, he then found the value of G by measuring the separation and inertias of the spheres. The value determined with modern instruments is

$$G = 6.6738 \times 10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2. \tag{13.5}$$

QUANTITATIVE TOOLS

Because G is exceedingly small, the force exerted by two 1-kg objects that are 1 m apart is a mere 6.7×10^{-11} N. For comparison, the force of gravity exerted by Earth on a hair is around 10^{-3} N—15 million times stronger! This comparison shows how exceedingly small the gravitational force is. Only when at least one of the two interacting objects has a very large mass (10^{11} kg at the minimum) does the gravitational force become sizeable.

EXAMPLE 13.3 Weighing Earth

Cavendish is said to have "weighed Earth" because his determination of G provided the first value for the planet's mass m_E. Given that the radius of Earth is about 6400 km and given the value of G in Eq. 13.5, determine m_E.

❶ **GETTING STARTED** I am given Earth's radius and G and must use these values to determine Earth's mass. An expression containing G and the acceleration due to gravity g seems a good place to begin.

❷ **DEVISE PLAN** Equation 13.4 gives the acceleration due to gravity near Earth's surface, g, in terms of G, R_E, and m_E. Knowing the values of g, G, and R_E, I can determine m_E.

❸ **EXECUTE PLAN** From Eq. 13.4, I obtain $m_E = gR_E^2/G$,

$$\text{so } m_E = \frac{(9.8 \text{ m/s}^2)(6.4 \times 10^6 \text{ m})^2}{(6.6738 \times 10^{-11} \text{ N} \cdot \text{m}^2/\text{kg}^2)} = 6.0 \times 10^{24} \text{ kg.} \checkmark$$

❹ **EVALUATE RESULT** Table 13.1 gives 5.97×10^{24} kg, which agrees with my answer to within less than 1%. Instead of looking up the value, I can also estimate Earth's mass to check my answer. Remember that we carried out that estimate in Checkpoint 1.16 and obtained 5×10^{24} kg, which is within 20% of my answer.

13.6 Gravitational potential energy

In Section 7.9 we determined the potential energy associated with the force of gravity near Earth's surface. Let us now obtain general expressions for the gravitational potential energy from the law of gravity. To do so, we consider two objects 1 and 2 of masses m_1 and m_2. Suppose the mass of object 1 is much greater than the mass of object 2, $m_1 \gg m_2$, so that if we place object 1 at the origin, we can consider it being fixed there. Now let object 2 move along the x axis from x_i to x_f under the influence of the gravitational attraction between the two (Figure 13.28). What is the work done by the gravitational force exerted by object 1 on object 2?

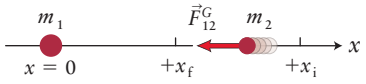


Figure 13.28 An object of mass m_2 moves toward an object of mass $m_1 \gg m_2$ held fixed at the origin.

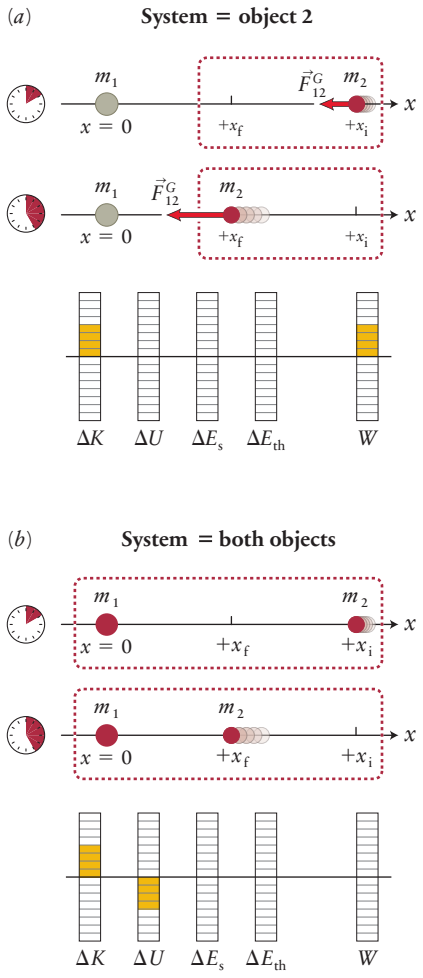
If we choose the x axis pointing to the right as indicated in Figure 13.28, the x component of the force exerted by object 1 on object 2 when object 2 is at some arbitrary position x is

$$F_{12x}^G = -G\frac{m_1 m_2}{x^2}. \tag{13.6}$$

The x component of the force is negative because the force points in the negative x direction. The gravitational force varies with distance, and so to evaluate the work done by object 1 on object 2, we must evaluate the integral (see Eq. 9.22):

$$W = \int_{x_i}^{x_f} F_x(x)dx. \tag{13.7}$$

Substituting Eq. 13.6 into Eq. 13.7, we obtain



$$W = -Gm_1m_2\int_{x_i}^{x_f}\left(\frac{1}{x^2}\right)dx = Gm_1m_2\left[\frac{1}{x}\right]_{x_i}^{x_f} = Gm_1m_2\left(\frac{1}{x_f} - \frac{1}{x_i}\right). \tag{13.8}$$

This is the work done by the gravitational force exerted by object 1 on the system consisting of object 2 only (Figure 13.29*a* on the next page). Because the force and the displacement point in the same direction, we know that the work must be positive. Indeed, the right side of Eq. 13.8 is positive because $x_f < x_i$.

As object 2 moves from x_i to x_f, it accelerates, and so its kinetic energy increases. Because no other energy associated with it changes, the increase

QUANTITATIVE TOOLS

Figure 13.29 Energy diagrams for the situation shown in Figure 13.28.

in the kinetic energy must be equal to the work done on it by object 1, $\Delta K = W$, as illustrated in the energy diagram in Figure 13.29*a*.

If, instead of object 2 by itself, we now consider the (closed) system of the two interacting objects as a whole, then the increase in the kinetic energy of object 2 is due not to the work done by the external gravitational force exerted by object 1 on it but to a decrease in the gravitational potential energy of the system (Figure 13.29*b* and compare with Figure 9.18). This gravitational potential energy is a measure of the configuration of the system. The change in the gravitational potential energy of the system is thus $\Delta U^G = -\Delta K$. Because the change in kinetic energy does not depend on the choice of system, we see that the change in potential energy of the two-object system is the negative of W in Eq. 13.8:

$$\Delta U^G = Gm_1m_2\left(\frac{1}{x_i} - \frac{1}{x_f}\right). \tag{13.9}$$

It is customary to choose the gravitational potential energy of a system to be zero at infinite separation ($x = \infty$), which is the separation distance at which the gravitational force is zero: $U^G(\infty) = 0$. So, if we let object 2 move in from $x = \infty$ to an arbitrary position x under the influence of the gravitational acceleration due to object 1, Eq. 13.9 yields

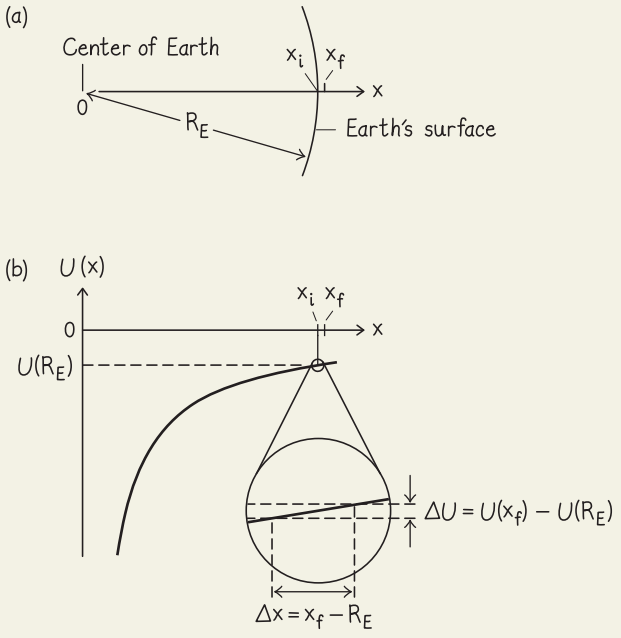
$$\Delta U^G = U^G(x) - U^G(\infty) = U^G(x) - 0 = Gm_1m_2\left(0 - \frac{1}{x}\right), \tag{13.10}$$

so the **gravitational potential energy** is

$$U^G(x) = -G\frac{m_1m_2}{x}, \tag{13.11}$$

which is zero at infinite x. As object 2 moves in from infinitely far away, its kinetic energy increases, and so the potential energy of the two-object system decreases. Therefore setting $U^G(\infty) = 0$ at $x = \infty$ causes the potential energy to be negative for all values of $x < \infty$.

EXAMPLE 13.4 Gravitational potential energy near Earth's surface



The distance between Earth's surface and an object of mass m is changed by an amount Δx. Show that when $x \approx R_E$ and $\Delta x \ll R_E$, where R_E is the radius of Earth, the general expression for gravitational potential energy, Eq. 13.9, reduces to the expression $\Delta U^G = mg\Delta x$ (Eq. 7.19).

❶ **GETTING STARTED** I begin by choosing an x axis that is perpendicular to Earth's surface and has the origin $x = 0$ at Earth's center. I then mark off a distance $x = R_E$ on this axis (**Figure 13.30***a*). Because I'm told that $x \approx R_E$ and $\Delta x \ll R_E$, I let the initial position x_i be right at Earth's surface, $x = R_E$, and the final position x_f be just to the right of x_i.

To get some feel for the situation, I also graph the gravitational potential energy of Earth from Eq. 13.11, marking the object's initial and final positions (Figure 13.30*b*). Basically, the problem requires me to show that when x_i and x_f lie sufficiently close to each other, ΔU^G is linearly proportional to Δx. Graphically this is already clear from my graph: If I blow up the region around $x_i = R_E$, the $U^G(x)$ curve is linear.

❷ **DEVISE PLAN** If I substitute $x_i = R_E$ and $x_f = R_E + \Delta x$ into Eq. 13.9, I can obtain an expression showing how ΔU^G depends on Δx. I can then approximate the resulting expression for $\Delta x \ll R_E$.

Figure 13.30

QUANTITATIVE TOOLS

3 EXECUTE PLAN After I substitute the masses of Earth and the object, $x_i = R_E$, and $x_f = R_E + \Delta x$, Eq. 13.9 becomes

$$\Delta U^G = Gm_E m\left(\frac{1}{R_E} - \frac{1}{R_E + \Delta x}\right). \qquad (1)$$

I know that $\Delta x \ll R_E$ in this problem, so I can write the second term in the parentheses as

$$\frac{1}{R_E + \Delta x} = \frac{1}{R_E}\left(\frac{1}{1 + \Delta x/R_E}\right) \approx \frac{1}{R_E}\left(1 - \frac{\Delta x}{R_E}\right) \qquad (2)$$

because, for any small number $\epsilon \ll 1$, $1/(1+\epsilon) \approx 1 - \epsilon$ (see Appendix B). Substituting Eq. 2 into Eq. 1, I obtain

$$\Delta U^G = Gm_E m\left[\frac{1}{R_E} - \frac{1}{R_E}\left(1 - \frac{\Delta x}{R_E}\right)\right]$$

$$= Gm_E m\frac{\Delta x}{R_E^2} = m\frac{Gm_E}{R_E^2}\Delta x.$$

When I substitute, from Eq. 13.4, $g = Gm_E/R_E^2$, this expression becomes $\Delta U^G = mg\Delta x$. ✔

4 EVALUATE RESULT This result confirms the conclusion I drew from my sketch: $U^G(x)$ is curved, but for sufficiently small displacements Δx, the curve can be approximated by a straight line. Near Earth's surface the slope of this line is mg.

Because the force of gravity is a central force, we can easily generalize Eq. 13.11 to more than one dimension. Suppose object 2 moves from P to Q in **Figure 13.31*a*** along part of an elliptical orbit. Let us first approximate the displacement of object 2 by two successive displacements: one along the radial direction from P to R and one along a circular arc from R to Q. The work done by the force of gravity on object 2 over the radial displacement is given by Eq. 13.8. Along the circular arc RQ, the magnitude of the force of gravity is constant but always oriented perpendicular to the displacement. Because the work in more than one dimension is given by the scalar product of the force and the force displacement (Eq. 10.35), the work done by the force of gravity on object 2 along the circular arc is zero:

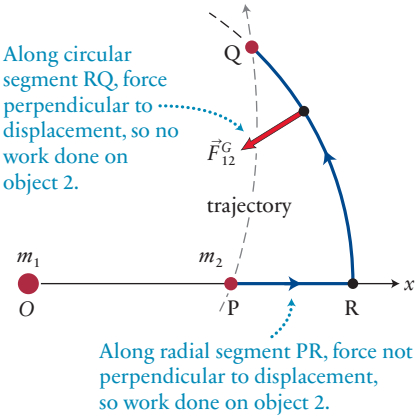
$$W_{R\to Q} = \int_R^Q \vec{F}_{12}^G \cdot d\vec{r} = 0. \qquad (13.12)$$

So the work done by object 1 on object 2 as it moves from P to Q along the path PRQ is equal to the work done along the radial displacement only.

A better approximation of the actual path of object 2 can be obtained by breaking down the motion into small segments and approximating each segment by the sum of radial and circular displacements, as shown in Figure 13.31*b*. Again, the work done on object 2 along each circular displacement is zero. Furthermore, all the radial displacements simply add up to the same radial displacement as in Figure 13.31*a*. So only the change in radial distance matters and the gravitational work done by object 1 on object 2 while object 2 moves from P to Q is

$$W_{P\to Q} = Gm_1m_2\left(\frac{1}{r_Q} - \frac{1}{r_P}\right), \qquad (13.13)$$

where r_P and r_Q are the magnitudes of the position vectors of object 2 at P and Q, respectively. Following the same line of reasoning that led from Eq. 13.8 to Eq. 13.11, we can write for the gravitational potential energy of the system



$$U^G(\vec{r}) = -G\frac{m_1m_2}{r} \quad \text{(zero at infinite } r\text{)}, \qquad (13.14)$$

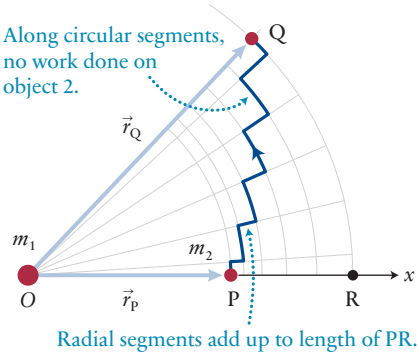
where r is the distance between the two objects.

Note that the result we obtained in Eq. 13.13 holds for *any* path that leads from P to Q. Any arbitrary path can be broken down into small radial and circular segments, and as Figure 13.31*b* shows, the work done by the gravitational force depends only on the position of the endpoints

Figure 13.31 To calculate the work done by object 1 on object 2 while object 2 moves along the dashed path from P to Q, we approximate the path by (*a*) one radial and one circular displacement or (*b*) a number of successive such displacements.

(*a*) Trajectory approximated by one radial segment PR and one circular segment RQ

(*b*) Trajectory approximated by multiple radial and circular segments



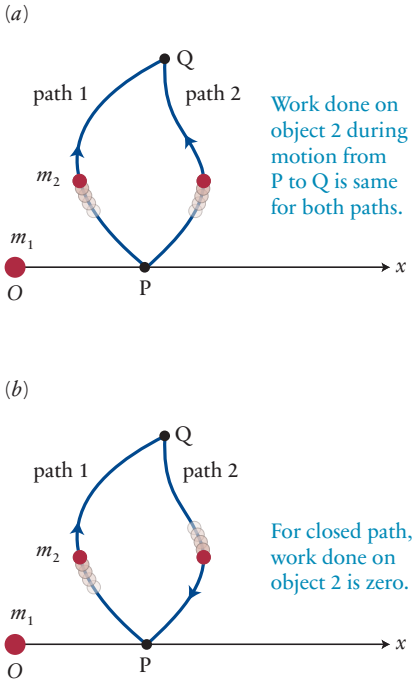


Figure 13.32 The gravitational work done on object 2 depends only on the endpoints.

relative to m_1, not on the path taken. Consider for example paths 1 and 2 from P to Q in **Figure 13.32a**. The work done is the same along both paths:

$$W_{\mathrm{P}\to\mathrm{Q},\ \text{path 1}} = W_{\mathrm{P}\to\mathrm{Q},\ \text{path 2}}. \tag{13.15}$$

This path independence is characteristic of nondissipative interactions (see Section 7.8).

We also know that the work done along a path moving in one direction is the negative of the work done along that path moving in the opposite direction. This can readily be seen in Figure 13.31*b*: Reversing the direction of travel inverts the sign of the displacement (and therefore the sign of the work) along all radial components. So if we let object 2 move from Q to P along path 2 in Figure 13.32*a*, the work done on it is

$$W_{\mathrm{Q}\to\mathrm{P},\ \text{path 2}} = -W_{\mathrm{P}\to\mathrm{Q},\ \text{path 2}}. \tag{13.16}$$

A consequence of Eqs. 13.15 and 13.16 is that if an object moves from P to Q along path 1 and then back to P along path 2, as shown in Figure 13.32*b*, then the work done by the gravitational force on the object is zero:

$$W = W_{\mathrm{P}\to\mathrm{Q},\,\text{path 1}} + W_{\mathrm{Q}\to\mathrm{P},\,\text{path 2}} = W_{\mathrm{P}\to\mathrm{Q},\,\text{path 2}} + (-W_{\mathrm{P}\to\mathrm{Q},\,\text{path 2}}) = 0. \tag{13.17}$$

A path like the one shown in Figure 13.32*b*, in which any object following the path returns to its original position, is called a **closed path.** Because the gravitational potential energy depends only on the position of the endpoints and the endpoints are the same, the change in the potential energy of the two-object system is zero. Consequently the work done by the gravitational force exerted by one object on the other as it moves along a closed path is zero, as Eq. 13.17 shows.

13.18 Near Earth's surface, when $\Delta U^G = mg\Delta x$, it is customary to let the gravitational potential energy be zero at Earth's surface, instead of at infinite separation as we did in Eq. 13.10. Does this choice of zero yield greater or smaller values for the gravitational potential energy? By what amount?

13.7 Celestial mechanics

Now that we have derived an expression for the gravitational potential energy, we can write an expression for the energy of a system of two celestial objects. Consider a system consisting of two objects of which one has a much greater mass than the other ($M \gg m$), so that we can consider the center of mass of the two-object system to be fixed at the center of the larger object (see Section 13.2). Examples of such a system are a planet orbiting a star, a moon orbiting a planet, and a satellite orbiting Earth (**Figure 13.33**). For convenience we'll refer to the object with the greater mass M as the *star* and the object with the smaller mass m as the *satellite,* but the results apply to any pair of celestial objects with $M \gg m$. (Technically, satellites orbit planets, not stars. A planet could have the greater mass M or the smaller mass m, so using "star" throughout this discussion avoids that confusion.) We shall consider the system to be closed and isolated so that neither its energy nor its angular momentum can change:

$$\Delta E = 0 \quad \text{and} \quad \Delta\vec{L} = \vec{0}. \tag{13.18}$$

The energy of the system consists of the gravitational potential energy and the kinetic energy. Because only the satellite is in motion, we have

$$E = K + U^G = \tfrac{1}{2}mv^2 - \frac{GMm}{r}, \tag{13.19}$$

where v is the satellite's speed and r is the distance between satellite and star.

QUANTITATIVE TOOLS

Because the force of gravity is central, the angular momentum of each object is constant. For the satellite we have

$$L = r_{\perp} mv. \tag{13.20}$$

Equations 13.18–13.20 allow us to determine the shape of the satellite's orbit given the values of $\vec{r}$ and $\vec{v}$ at any given instant.

13.19 (*a*) If an object of mass m is released from rest a distance r from a star of mass $M \gg m$ and radius R_s, is the mechanical energy of the star-object system E_{mech} positive, negative, or zero? (*b*) Describe the motion of the object, and determine the maximum and minimum values of its kinetic energy during its motion. (*c*) Does the motion you described in part *b* satisfy conservation of angular momentum about the center of the star? (*d*) Suppose the object is now launched with nonzero velocity in a direction perpendicular to the straight line joining it and the center of the star. Is E_{mech} positive, negative, or zero?

As this checkpoint shows, the mechanical energy E_{mech} of a star-satellite system can be negative because U^G is always negative when we let the gravitational potential energy be zero at infinite separation. To understand the consequences of the energy being negative, look at **Figure 13.34**, which shows the gravitational potential energy U^G as a function of the distance r between satellite and star. As we saw in Section 13.6, U^G has a $1/r$ dependence and approaches zero as r goes to infinity. If the energy E of the system is negative, then there is a value $r = r_{max}$ for which $U^G = E_{mech}$—all of the mechanical energy is in the form of potential energy, and thus the satellite's kinetic energy is zero. Any separation distance r greater than r_{max} would yield a negative kinetic energy because $U^G > E_{mech}$ for $r > r_{max}$. Because the kinetic energy cannot be negative, the satellite's motion for negative values of E_{mech} is restricted to values of $r < r_{max}$ for which $U^G < E_{mech}$. The maximum separation distance r_{max} occurs when $U^G = E_{mech}$:

$$-\frac{GMm}{r_{max}} = E_{mech} \tag{13.21}$$

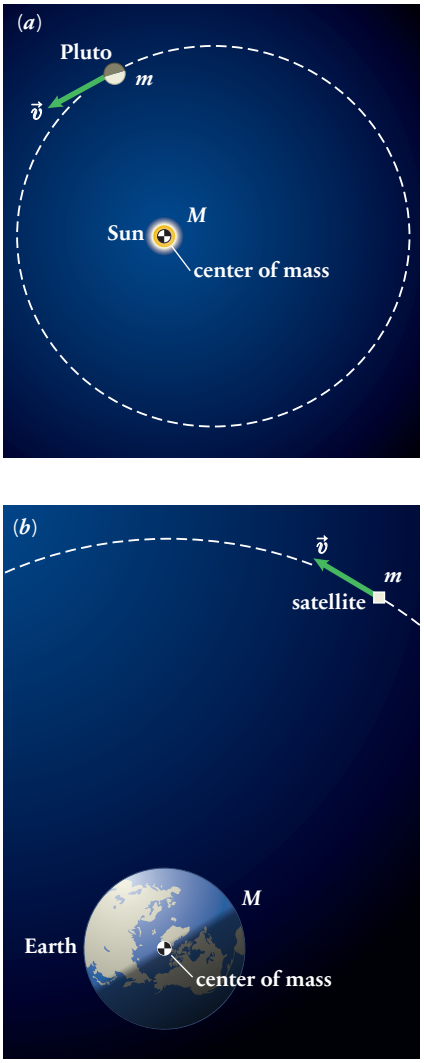
$$r_{max} = \frac{GMm}{-E_{mech}}. \tag{13.22}$$

In words, we say that for negative E_{mech}, the satellite is *bound* to the star: It cannot escape to infinity because it does not have enough kinetic energy. When the mechanical energy E_{mech} is positive, the gravitational potential energy is *always* smaller than E_{mech}, and so even at infinite separation, where the gravitational potential energy is maximum, there still is a positive amount of kinetic energy. Therefore there is no limit on the separation distance r for $E_{mech} > 0$; in this case, we say the satellite is *unbound* because it has enough energy to "escape" to infinity.

13.20 (*a*) If a satellite of mass m were to reach the position r_{max} given by Eq. 13.22, what would its angular momentum be? (*b*) What would its trajectory have to be to satisfy conservation of angular momentum? (*c*) If its angular momentum is nonzero, can the satellite ever reach r_{max}?

To determine the shape of the satellite's orbit, we must solve Eqs. 13.18–13.20. The solution of these simultaneous equations yields orbits that correspond to the *conic sections* illustrated in **Figure 13.35** on the next page, with the star at the focus of the section. The sections shown in the figure

Figure 13.33 When one object orbits another that has much greater mass, we can consider the center of mass of the system to be fixed at the center of the larger object.



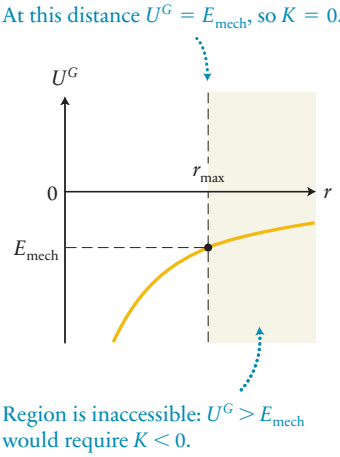


Figure 13.34 When the mechanical energy E_{mech} of a system is negative, the separation distance r between two objects in the system is limited to the region where $U^G < E_{mech}$.

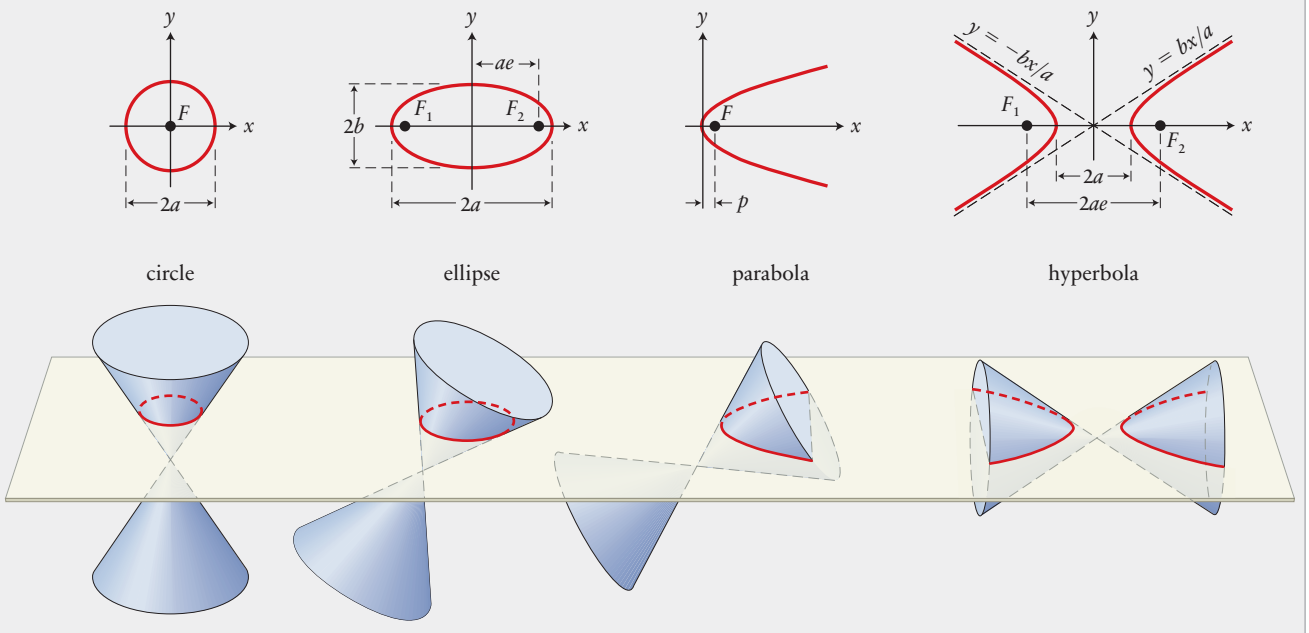
Conic sections

Second-degree equations in two variables of the form

$$Ax^2 + Bxy + Cy^2 + Dx + Ey + F = 0$$

are called **conic sections** because the curves they represent can be obtained by intersecting a plane and a circular cone (Figure 13.35). These curves can also be written in the form

$$\frac{x^2}{a^2} + \frac{y^2}{a^2(1-e^2)} = 1, \qquad (1)$$



where a is the semimajor axis (see Figure 13.7) of the section and e is the eccentricity.

Ellipse: For $0 \le e < 1$, we obtain an ellipse with a semimajor axis a and a semiminor axis b with $b^2 = a^2(1-e^2)$, where e is the eccentricity of the ellipse. For each point on the ellipse, the sum of the distances to the two foci at $(\pm ae, 0)$ is equal to $2a$. A special type of ellipse is obtained for $e = 0$: The two foci coincide, and the ellipse becomes a **circle** of radius a.

Hyperbola: When $e > 1$, the term that contains y^2 becomes negative, and Eq. 1 yields the two branches of a hyperbola with foci at $(\pm ae, 0)$ and oblique asymptotes $y = \pm(b/a)x$, with $b^2 = a^2(e^2-1)$. For each point on the hyperbola, the difference of the distances to the foci is equal to $2a$.

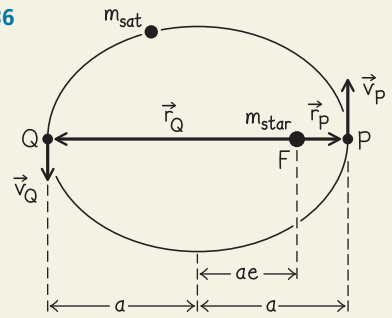
The limiting case between an ellipse and a hyperbola, which occurs when $e = 1$, yields a **parabola** of the form $y^2 = 4px$. The parabola can be thought of as an elongated ellipse with one focus at $(p, 0)$ and the other at $(\infty, 0)$.

Figure 13.35 Conic sections.

fall into two categories: *ellipses* (including the *circle*, which is a special type of ellipse) and *hyperbolas*. The limiting section between these two categories is the *parabola*. Ellipses are bound and therefore correspond to negative mechanical energy; hyperbolas are unbound and thus correspond to positive mechanical energy. The limiting case between bound and unbound motion occurs for $E_{\text{mech}} = 0$, when the satellite has just enough kinetic energy to approach infinity (with zero kinetic energy). The corresponding orbit is the parabola. Summarizing, we have

$E_{\text{mech}} < 0$: elliptical orbit

$E_{\text{mech}} = 0$: parabolic orbit



$E_{\text{mech}} > 0$: hyperbolic orbit.

EXAMPLE 13.5 Rocket science

A satellite of mass m_{sat} is in an elliptical orbit around a star of mass $m_{star} \gg m_{sat}$. If the mechanical energy of the star-satellite system is E_{mech} and the magnitude of the angular momentum of the satellite about the star is L, what are the semimajor axis a and the eccentricity e of the satellite's orbit?

1 GETTING STARTED I begin by making a drawing of the system (**Figure 13.36**), placing the star at one focus (F) of the ellipse. I also mark the positions of smallest (P) and and greatest (Q) separation between star and satellite, because at those locations the position vector $\vec{r}$ from star to satellite is perpendicular to the satellite's velocity $\vec{v}$, and therefore it is relatively easy to calculate the angular momentum.

Figure 13.36

2 DEVISE PLAN From my diagram I see that the major axis of the ellipse is equal to the sum of the distances FP and FQ: $2a = r_P + r_Q$. I also see that the distance FP is equal to $a - ae = a(1-e)$, and so $a(1-e) = r_P$. If I know r_P and r_Q, I can determine a and e. I know that the satellite's angular momentum at P must be the same as its angular momentum at Q. I also know that the mechanical energy of the system must be the same at these two locations. Thus I have two equations, $L_P = L_Q = L$ and $E_P = E_Q = E_{mech}$, from which I can determine r_P and r_Q.

3 EXECUTE PLAN The magnitude of the satellite's angular momentum at P is the same as that at Q, so $L = m_{sat} r_P v_P = m_{sat} r_Q v_Q$. Using this expression, I can write for the satellite's kinetic energy at P:

$$K_P = \tfrac{1}{2} m_{sat} v_P^2 = \frac{m_{sat}^2 v_P^2 r_P^2}{2 m_{sat} r_P^2} = \frac{L^2}{2 m_{sat} r_P^2}.$$

The energy of the system at P is then

$$E_{mech} = K_P + U_P^G = \frac{L^2}{2 m_{sat} r_P^2} - \frac{G m_{sat} m_{star}}{r_P}. \quad (1)$$

After writing corresponding expressions for position Q and setting the system energy at P equal to that at Q, I get

$$\frac{L^2}{2 m_{sat} r_P^2} - \frac{G m_{sat} m_{star}}{r_P} = \frac{L^2}{2 m_{sat} r_Q^2} - \frac{G m_{sat} m_{star}}{r_Q}.$$

I now put both terms containing L on the left and combine them over their common denominator, put both terms containing G on the right and combine them over their common denominator, and work through the algebra to get

$$\frac{L^2}{2 m_{sat}} (r_P + r_Q) = G m_{sat} m_{star} r_P r_Q.$$

Substituting $r_P + r_Q = 2a$, $r_P = a(1-e)$, and $r_Q = 2a - r_P = a(1+e)$, I obtain, after some algebra,

$$L^2 = G m_{sat}^2 m_{star} a (1 - e^2). \quad (2)$$

Substituting this expression for L^2 into Eq. 1 and solving for a give

$$a = -\frac{G m_{sat} m_{star}}{2 E_{mech}}. \checkmark$$

Substituting this result for a into Eq. 2 and solving for e, I finally obtain

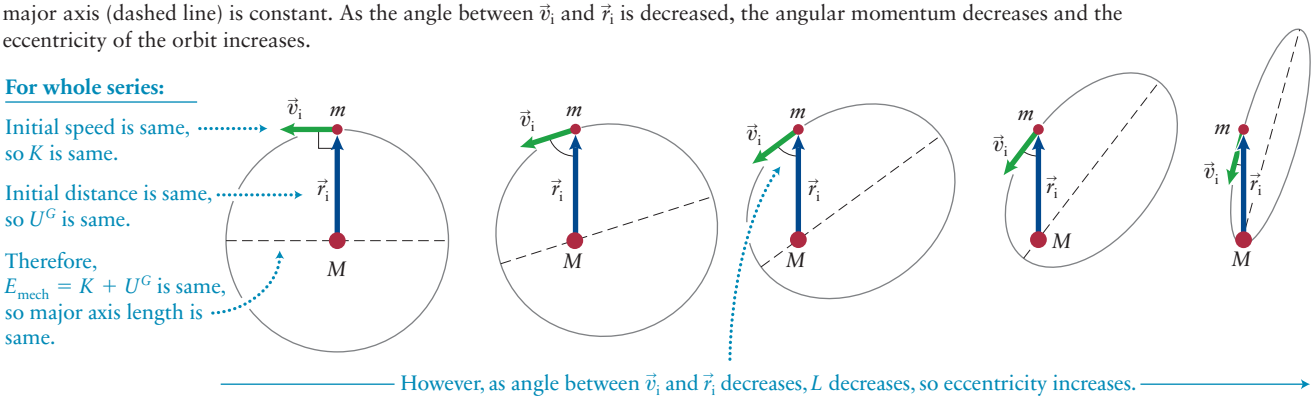
$$e = \sqrt{1 + \frac{2 E_{mech} L^2}{G^2 m_{sat}^3 m_{star}^2}}. \checkmark$$

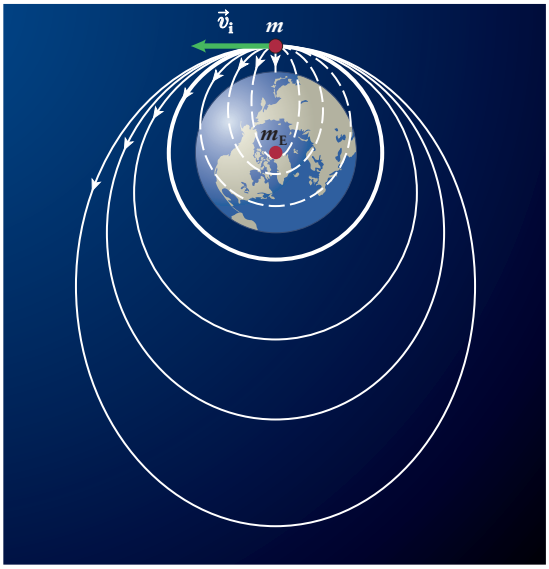
4 EVALUATE RESULT The orbit being elliptical means that E_{mech} is negative, and so a is positive and e is smaller than 1, as they should be for an ellipse. When $E_{mech} = 0$, the orbit should turn into a parabola and the satellite can go to infinity. Indeed, as I let E_{mech} approach zero, a approaches infinity and $e = 1$, and the ellipse turns into a parabola (see the box "Conic sections" on page 448).

13.21 Consider a planet of mass m moving at constant speed v in a circular orbit of radius R under the influence of the gravitational attraction of a star of mass M. (*a*) What is the planet's kinetic energy, in terms of m, M, G, and R? (*b*) What is the energy of the star-planet system? (*c*) Using the expression for the eccentricity obtained in Example 13.5, obtain an expression for E_{mech} for the circular orbit. (*d*) Compare your answers to parts *b* and *c*.

The results obtained in Example 13.5 show that the length $2a$ of the major axis of the ellipse depends on only the mechanical energy E_{mech} of the system. Because E_{mech} is negative, the greater E_{mech}, the closer it is to zero and the greater a.

Figure 13.37 Orbits of a satellite of mass m launched in different directions with fixed speed and a fixed distance from an object of mass M. Because the mechanical energy E_{mech} of the system is always the same, the length $2a$ of the orbit's major axis (dashed line) is constant. As the angle between $\vec{v}_i$ and $\vec{r}_i$ is decreased, the angular momentum decreases and the eccentricity of the orbit increases.





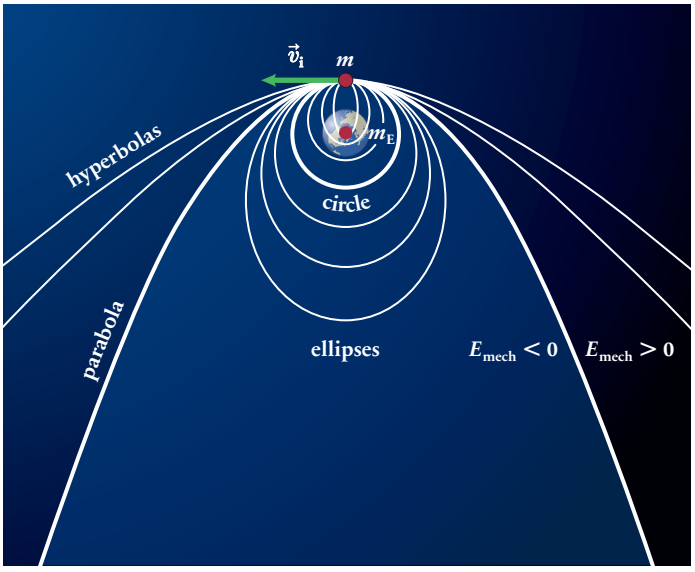


Figure 13.37 shows five orbits with the same fixed energy E_{mech} but different values of L. The energy $E_{mech} = U^G + K$ is fixed because the satellite is launched at a fixed initial speed (so K is fixed) from a point P that is a fixed distance r_i from the center of the larger object of mass M (so U^G is fixed). Because E_{mech} is fixed, the length $2a$ of the major axis is the same for all orbits. As the direction of $\vec{v}_i$ is changed (without changing the speed v_i and therefore E_{mech} and $2a$), the magnitude of the angular momentum changes, affecting the eccentricity of the orbit, which depends on both L and E_{mech}. For a fixed mechanical energy E_{mech} (that is to say, for a fixed value of the major axis), e increases as L decreases. So, as the angle between $\vec{v}_i$ and $\vec{r}_i$ gets smaller, the ellipse becomes more elongated. In all cases, the object of mass M is at one of the foci of the ellipse.

Figure 13.38 shows the orbits of an object launched multiple times from a fixed location that is a distance r_i from Earth's center. All launches are in the same direction, perpendicular to the straight line connecting the object to Earth's center, but the launch speed is increased for each successive launch. Because the initial gravitational potential energy U^G is always the same, the value of the mechanical energy E_{mech} is determined by the initial kinetic energy: $E_{mech} = U^G + K$.

Figure 13.38 Orbits of an object launched at different speeds from a fixed location that is a fixed distance r_i from Earth's center.

If the object is released from rest, $K = 0$ and so $E_{\text{mech}} = U^G$. As you saw in Checkpoint 13.19, the object falls in a straight line toward the surface of Earth. When the object is given a small initial speed, however, the orbit is an ellipse with Earth's center at the focus farther from the launch point. For small v_i, the orbit intersects Earth and the object crashes. As v_i is increased, the ellipse becomes rounder and longer, and for sufficiently great v_i, the object makes it around the planet.

As we continue to increase v_i, we reach a point when v_i has just the right magnitude to make v_i^2/r_i equal to the centripetal acceleration caused by Earth's gravitational force, and the object goes in a circular orbit. For greater v_i, the orbit is again elliptical, but Earth's center now coincides with the nearer focus of the ellipse.

As we continue to increase v_i, we reach a point where the mechanical energy E_{mech} of the Earth-object system is no longer negative and the orbit is unbound. This happens when

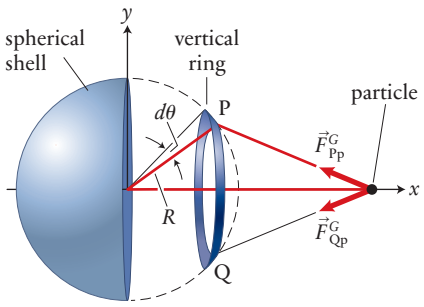
$$E_{\text{mech}} = \tfrac{1}{2}mv_{\text{esc}}^2 - \frac{Gmm_E}{r_i} = 0, \tag{13.23}$$

where v_{esc} is the object's *escape speed*, m is the mass of the launched object, m_E is Earth's mass, and r_i is the distance from the launch point to Earth's center. An object launched at the escape speed and moving without any further propulsion travels out to infinity along a parabolic path. At launch speeds greater than v_{esc} the orbit corresponds to one branch of a hyperbola.

13.22 (*a*) Determine an expression for the escape speed at Earth's surface. (*b*) What is the value of this escape speed? (*c*) Does it matter in which direction an object is fired at the escape speed?

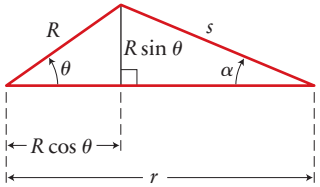
13.8 Gravitational force exerted by a sphere

Central to Newton's law of gravity is the statement that a solid sphere exerts a gravitational force on an object outside the sphere as if all its mass were concentrated at the center of the sphere. To prove this statement, we'll calculate the force exerted on a particle of mass m by a thin spherical shell of mass M and radius R; the distance between the particle and the center of the shell is r. Once we have a result for the shell, we can obtain the result for a solid sphere by treating the solid sphere as a large number of concentric spherical shells, like the layers of an onion.



Consider first a vertical ring-shaped piece of the shell—the portion contained between the angles θ and $\theta + d\theta$ in **Figure 13.39a**. The force exerted by a small segment of the ring near P is $\vec{F}^G_{\text{Pp}}$; the force by a small segment near Q is $\vec{F}^G_{\text{Qp}}$. Only the components of these forces along the x axis contribute to the vector sum of the forces exerted on the particle. The same cancellation occurs for every pair of diametrically opposite small segments that make up the entire ring. To calculate the vector sum of the forces exerted on the particle, we therefore need to consider only the x components. The x component of the force exerted by a small segment of the ring of mass dm near P on the particle is

$$dF^G_{\text{Pp}x} = -G\frac{m\,dm}{s^2}\cos\alpha, \tag{13.24}$$



where α is the angle between the force and the straight line from the particle to the center of the shell and s is the distance from the particle to P. The x components of the forces exerted by all segments of the ring have the

Figure 13.39 To calculate the gravitational force exerted by a spherical shell of mass M on an object of mass m, the shell is divided into vertical rings.

(*a*)

(*b*) Geometry of red triangle in part *a*.

same magnitude. The vector sum of the forces exerted by the whole ring is thus equal to the sum of the contributions from all segments of the ring:

$$dF_{\mathrm{rp}x}^{G} = -G\frac{m\,dM}{s^2}\cos\alpha, \tag{13.25}$$

where dM is the mass of the entire ring (the sum of the masses of all segments). The width of the ring being equal to the arc length $R\,d\theta$, the area of the ring is (length) $\times$ (width) $= (2\pi R\sin\theta)(R\,d\theta) = 2\pi R^2\sin\theta\,d\theta$. If the mass M of the entire shell is uniformly distributed over the shell, then the mass per unit area is $M/(4\pi R^2)$, so

$$dM = 2\pi R^2\sin\theta\,d\theta\frac{M}{4\pi R^2} = \frac{M}{2}\sin\theta\,d\theta \tag{13.26}$$

or, combining Eqs. 13.25 and 13.26,

$$dF_{\mathrm{rp}x}^{G} = -\frac{GMm}{2}\frac{\cos\alpha\sin\theta\,d\theta}{s^2}. \tag{13.27}$$

Equation 13.27 gives the force exerted by one vertical ring of our spherical shell on the particle. Now we must integrate this result over the entire shell. Before we can carry out this integration, we must reduce the variables α, s, and θ, which are all related, to one variable. From Figure 13.39*b* we see that

$$\cos\alpha = \frac{r - R\cos\theta}{s}, \tag{13.28}$$

and from the law of cosines (see Appendix B), we have

$$s^2 = R^2 + r^2 - 2rR\cos\theta. \tag{13.29}$$

Differentiating the left side of this equation with respect to s yields $2s$. For the right side we get

$$\begin{aligned}\frac{d}{ds}(R^2 + r^2 - 2rR\cos\theta) &= \frac{d}{d\theta}(R^2 + r^2 - 2rR\cos\theta)\frac{d\theta}{ds}\\ &= 2rR\sin\theta\frac{d\theta}{ds}.\end{aligned} \tag{13.30}$$

Equating the derivatives on the two sides, we get

$$2s = 2rR\sin\theta\frac{d\theta}{ds} \tag{13.31}$$

$$\sin\theta\,d\theta = \frac{s\,ds}{rR}. \tag{13.32}$$

Substituting Eq. 13.32 and $R\cos\theta$ from Eq. 13.29 into Eq. 13.28 and then into Eq. 13.27 yields

$$dF_{\mathrm{rp}x}^{G} = -\frac{GMm}{4r^2R}\frac{(r^2 + s^2 - R^2)ds}{s^2} = -\frac{GMm}{4r^2R}\left(\frac{r^2 - R^2}{s^2} + 1\right)ds. \tag{13.33}$$

QUANTITATIVE TOOLS

To obtain the force exerted by the entire shell, we must integrate this expression from $s = r - R$ (at $\theta = 0$) to $s = r + R$ (at $\theta = \pi$):

$$F^G_{\text{sp}x} = \int_{r-R}^{r+R} dF^G_{\text{rp}x} = -\frac{GMm}{4r^2R}\int_{r-R}^{r+R}\left(\frac{r^2 - R^2}{s^2} + 1\right)ds. \tag{13.34}$$

Working out the integral (see Checkpoint 13.23), we get

$$\int_{r-R}^{r+R}\left(\frac{r^2 - R^2}{s^2} + 1\right)ds = 4R \tag{13.35}$$

so

$$F^G_{\text{sp}x} = -G\frac{Mm}{r^2} \quad \text{(shell)}, \tag{13.36}$$

where the minus sign indicates that the force points toward the center of the shell. So we see that the shell exerts a force as if its entire mass M were concentrated at the center.

We can now easily extend this result to a solid sphere by considering many concentric shells. For each shell, we obtain an expression of the form given by Eq. 13.36; adding all terms (one for each shell) then yields

$$F^G_{\text{sp}} = G\frac{mM_{\text{sphere}}}{r^2} \quad \text{(sphere)} \tag{13.37}$$

for the magnitude of the gravitational force exerted by a solid sphere of mass M_{sphere} on a particle of mass m placed a distance r from the sphere's center. Equation 13.37 shows that the solid sphere exerts a force as if its entire mass M were concentrated at the center.

13.23 (*a*) Work out the integral in Eq. 13.35. (*b*) Show that Eq. 13.33 still holds if the particle of mass m is inside the shell. (*c*) What are integration limits with this particle inside the shell? What is the value of the integral in Eq. 13.35 for these limits?

Chapter Summary

Universal gravity and the principle of equivalence (Sections 13.1, 13.3–13.5, 13.8)

Concepts The force of gravity is an attraction between all objects that have **mass,** which is a measure of the quantity of material in an object. Mass is the property of an object that determines the strength of its gravitational interaction with other objects.

At everyday speeds, the mass of an object is equal to its inertia.

According to the **principle of equivalence,** one cannot distinguish locally between the effects of a constant gravitational acceleration of magnitude g and the effects of an acceleration of the reference frame of magnitude $a = g$.

Quantitative Tools According to Newton's **law of gravity,** if two objects that have masses m_1 and m_2 are a distance r apart, the magnitude of the gravitational force that each object exerts on the other is

$$F_{12}^G = G\frac{m_1 m_2}{r_{12}^2}, \tag{13.1}$$

where $G = 6.6738 \times 10^{-11}\ \mathrm{N \cdot m^2/kg^2}$ is the **gravitational constant.**

The acceleration due to gravity near Earth's surface is

$$g = \frac{Gm_E}{R_E^2}, \tag{13.4}$$

where m_E is Earth's mass and R_E is its radius.

The gravitational force F_{sp}^G exerted by a uniform solid sphere on a particle of mass m is the same as if all the matter in the sphere were concentrated at its center:

$$F_{sp}^G = G\frac{mM_{sphere}}{r^2}, \tag{13.37}$$

where M_{sphere} is the mass of the sphere and r is the distance from its center to the particle.

Angular momentum and gravitational potential energy (Sections 13.2, 13.6)

Concepts The force of gravity is a **central force,** meaning that its line of action always lies along the line connecting the interacting objects.

In an isolated system of two objects that interact through a central force, each object has a constant angular momentum about the center of mass of the system.

Quantitative Tools The **gravitational potential energy** $U^G(x)$ of a system made up of two objects of masses m_1 and m_2 that are a distance x apart is

$$U^G(x) = -G\frac{m_1 m_2}{x}, \tag{13.11}$$

where we take $U^G(x)$ to be zero at $x = \infty$.

Celestial mechanics (Sections 13.2, 13.7)

Concepts **Kepler's first law of planetary motion:** All planets move in elliptical orbits with the Sun at one focus. This law is a consequence of the fact that the magnitude of the gravitational force has a $1/r^2$ dependence.

Kepler's second law: The straight line from any planet to the Sun sweeps out equal areas in equal time intervals. This law reflects the fact that the angular momentum of a planet is constant because the gravitational force is a central force.

Kepler's third law: The squares of the periods T of the planets are proportional to the cubes of the semimajor axes a of their orbits around the Sun ($T^2 \propto a^3$). This law is a consequence of the fact that the magnitude of the gravitational force has a $1/r^2$ dependence.

Quantitative Tools The energy of a closed ($\Delta E = 0$), isolated ($\Delta L = 0$) system made up of a small object of mass m orbiting a large object of mass $M \gg m$ is

$$E = K + U^G = \tfrac{1}{2}mv^2 - G\frac{Mm}{r}, \tag{13.19}$$

where v is the speed of the small object, r is the distance between the objects, and the large object does not move.

The magnitude of angular momentum of the small object is

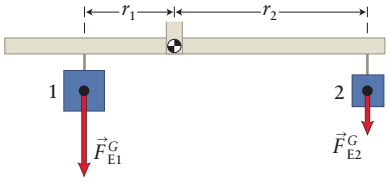
$$L = r_\perp mv. \tag{13.20}$$

The value of E in Eq. 13.19 determines the orbit's shape:

$E_{mech} < 0$: elliptical (bound) orbit
$E_{mech} = 0$: parabolic orbit
$E_{mech} > 0$: hyperbolic (unbound) orbit.

Questions and Problems

For instructor-assigned homework, go to Mastering Physics



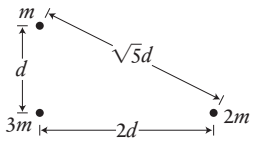
Dots indicate difficulty level of problems: • = *easy,* •• = *intermediate,* ••• = *hard;* CR = *context-rich problem.*

[It is convenient for some problems to note that $G = 6.67 \times 10^{-11}\ \text{N} \cdot \text{m}^2/\text{kg}^2 = 6.67 \times 10^{-11}\ \text{m}^3/(\text{kg} \cdot \text{s}^2)$.]

13.1 Universal gravity

1. If the matter that makes up a planet is distributed uniformly so that the planet has a fixed, uniform density, how does the magnitude of the acceleration due to gravity at the planet surface depend on the planet radius? •
2. In Figure P13.2, suppose the mass of object 1 is three times the mass of object 2. (*a*) At Earth's surface, what ratio r_1/r_2 is needed to have the rod stay horizontal? (*b*) What is this ratio on the Moon, where the magnitude of the gravitational force is only one-sixth of the magnitude of Earth's gravitational force? •

Figure P13.2

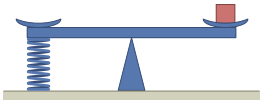


3. Suppose you're making a scale model of the solar system showing the eight planets (not including the dwarf planet Pluto) and having each planet at its farthest position from the Sun. If you use a marble of radius 10 mm for Mercury, how far from the Sun must you place your outermost planet? •
4. Four identical objects are placed at the four corners of a square, far from any star or planet. (*a*) Choose one object and draw to scale the vectors that represent the gravitational forces exerted on it by the other three objects. (*b*) Draw a vector that represents the vector sum of the forces exerted on your chosen object. ••
5. Two basketballs, each of mass 0.60 kg and radius 0.12 m, are placed on a floor so that they touch each other. Two golf balls, each of mass 0.045 kg and radius 22 mm, are placed on a table so that they touch each other. What is the ratio of the gravitational force exerted by one basketball on the other to that exerted by one golf ball on the other? ••

13.2 Gravity and angular momentum

6. An astronaut on the International Space Station gently releases a satellite that has a mass much smaller than the mass of the station. Describe the motion of the satellite after release. •
7. An isolated object of mass m can be split into two parts of masses m_1 and m_2. Suppose the centers of these parts are then separated by a distance r. What ratio of masses m_1/m_2 would produce the largest gravitational force on each part? ••
8. Particles of mass m, $2m$, and $3m$ are arranged as shown in Figure P13.8, far from any other objects. These three particles interact only gravitationally, so that each particle experiences a vector sum of forces due to the other two. Call these $\vec{F}_m$, $\vec{F}_{2m}$, and $\vec{F}_{3m}$. (*a*) Show that the lines of action of $\vec{F}_m$, $\vec{F}_{2m}$, and $\vec{F}_{3m}$ intersect at a common point. (*b*) Is this point of intersection the center of mass of the system? (*c*) Is the analysis of the motion of this system straightforward? ••

Figure P13.8



9. Angular momentum can be represented as a vector product and interpreted in terms of the rate of change of an area with respect to time. Give a similar interpretation of another vector product: torque. (Hint: Consider derivatives.) •••

13.3 Weight

10. Suppose the spring/balance device in Figure P13.10 is adjusted so that the spring is slightly stretched and the balance arm is level when the device is in an elevator at rest relative to the ground and a 1.0-kg object is placed as shown. If the elevator accelerates upward, does the balance arm tilt clockwise, tilt counterclockwise, or remain level? •

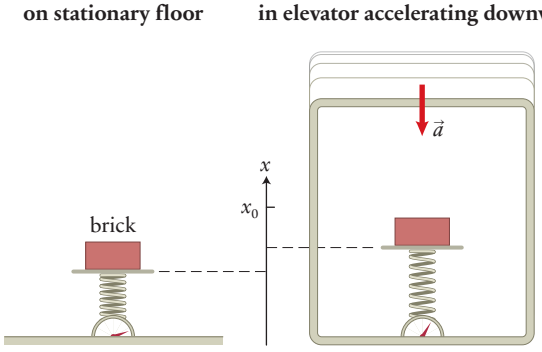


Figure P13.10

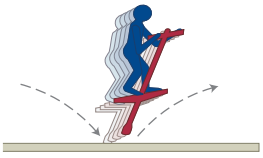
11. A certain metallic structure weighs 2450 N on earth. The structure is sent to Mars, which has a diameter of 6.78×10^6 m and mass of 6.42×10^{23} kg. What is the weight of the structure on the surface of the Martian planet? ••
12. A balance is purposefully prepared in an unbalanced condition, with too much mass on one side. It is carefully held with two hands, one on the base of the balance and one on the heavier end, so that the balance arm is level. Then both hands release the system from rest at the same instant. While it is in free fall, what happens to the balance arm? ••



13. (*a*) For what downward acceleration does the spring scale in Figure P13.13 read zero? (*b*) What would the answer in part *a* be if the experiment were done on the Moon? (*c*) How would your conclusion about the spring forces change if the brick were hung from the spring scale rather than supported by it? (Ignore the weight of the spring.) ••

Figure P13.13

14. You ride your pogo stick (Figure P13.14) across a diving board and into the local swimming pool. Your pogo stick is a special model equipped with a sensor that records the force measured by the spring. Describe the values of force recorded during your ride, using the gravitational force exerted on you by Earth as a benchmark. ••

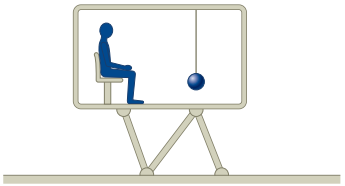


Figure P13.14

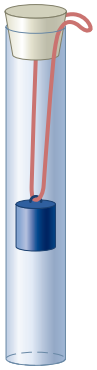
13.4 Principle of equivalence

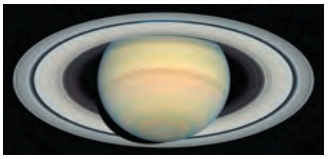


15. A person in an elevator lets go of his briefcase but observed that it moves towards the ceiling. How is the elevator moving? ••
16. How should the simulator in Figure P13.16 be tilted to simulate a left turn in a bobsled? Assume that the bobsled run has banked turns and that the sled exerts no tangential force on the ice. ••

Figure P13.16

17. A vertical accelerometer for measuring accelerations on a roller coaster can be constructed using a piece of clear plastic pipe, a cork, a rubber band, and a metal bob (Figure P13.17). Where the bob hangs down normally is where you make a mark for an acceleration of *g*. Without accelerating the pipe, explain how you can calibrate the accelerometer as you assemble it for accelerations of 2*g*, 3*g*, and so on. (Extra bobs are available.) ••

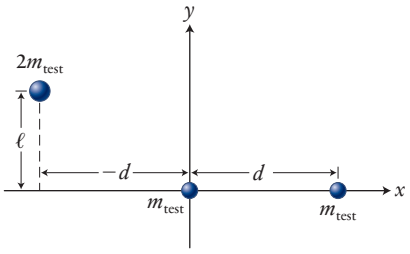
Figure P13.17



18. Consider two satellites simultaneously launched 180 km apart at the equator, each placed in a circular orbit that passes above the North Pole and its launch point. (*a*) Describe their relative motion with respect to Earth and with respect to each other. (*b*) Does this motion imply that each satellite exerts a force on the other? ••
19. Let us explore whether there is any way to distinguish acceleration due to rotation from acceleration due to a gravitational force. Imagine a deep bowl with a small volume of milk in it. (*a*) What happens to the milk when you spin the bowl about a perpendicular axis that runs through the center of the bowl bottom? (*b*) What is the shape of an object that exerts a gravitational force that could make the milk behave in a similar fashion? •••

13.5 Gravitational constant

20. Consider two speres in a system—Sphere 1 has mass M and radius $2R$, while the second Sphere has mass $2M$ and radius R. If the two spheres touch each other, find the magnitude of their gravitational force of attraction as a function of mass M and radius R. •
21. Two spherical celestial bodies, one of mass 3.5×10^{13} kg and the other of mass 2.4×10^{18} kg, experience a gravitational force between them with a magnitude of 4.0×10^{7} N. How far apart are the two spheres? ••
22. A 2.0×10^{9}-kg sphere is at the origin, and a second 5.0×10^{9}-kg sphere is on the x-axis at $x = 8.0$ km. Find the magnitude and direction of the net gravitational attraction force that the two spheres would exert on a third sphere of mass 9.1×10^{3} kg placed at $x = 2.0$ km. ••
23. The mass of a hypothetical planet is 1/80 that of Earth and its radius is 1/4 that of Earth. What is the ratio of the acceleration due to gravity on the planet to that on Earth? ••
24. Gravity is the weakest of the fundamental interactions (see Section 7.6). (*a*) This being so, what makes it such an important force on Earth? (*b*) What makes it the dominant force in galaxies? ••
25. A neutron star has about two times the mass of our Sun but has collapsed to a radius of 10 km. What is the acceleration due to gravity on the surface of this star in terms of the free-fall acceleration at Earth's surface? ••
26. Which pulls harder on the Moon: Earth or the Sun? ••
27. How far above the surface of Earth do you have to go before the acceleration due to gravity drops by 0.10%, 1.0% and 10%? ••
28. (*a*) As a spacecraft travels along a straight line from Earth to the Moon, at what distance from Earth does the force of gravity exerted by Earth on the coasting spacecraft cancel the force of gravity exerted by the Moon on the spacecraft? (*b*) What do the passengers in the spacecraft notice, if anything, before and after passing this location? ••



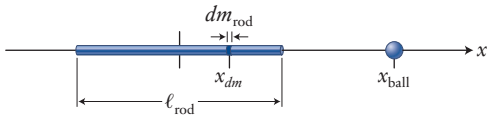
29. From the picture of Saturn in Figure P13.29 and known values, estimate the orbital period of particles in Saturn's rings. ●●

Figure P13.29

30. The Sun exerts a gravitational force on the Earth, keeping it in its orbit. (*a*) As per Newton's third law, what is the reaction to this force? (*b*) Suppose another planet has the same mass as the Earth but is located twice as far from the Sun. Describe the magnitude of the attraction force. ●
31. The acceleration of gravity on the surface of the Moon is about 1/6 of Earth's *g*. If the radius of the moon is 1,737.4 km, approximate the mass of the Moon from the given information. ●●
32. At what height above the surface of Pluto is the acceleration due to gravity half its surface value? ●●
33. Three spheres are arranged on a line along the *x*-axis. Sphere $m_1 = 5.00$ kg and is at the origin while sphere m_2 is at $x = +35.0$ m. What must be the mass of the second sphere if the net gravitational attraction force experience by a third sphere of mass 2.00 kg at $x = +20.0$ m is zero? ●●

Figure P13.33

34. Using *g* for the acceleration due to gravity is valid as long as the height *h* above Earth's surface is small. Derive an expression for a more accurate value of the acceleration due to gravity as a quadratic function of *h*. ●●●
35. Calculate the acceleration due to gravity *inside* Earth as a function of the radial distance *r* from the planet's center. (Hint: Imagine that a mine shaft has been drilled from the surface to Earth's center and an object of mass *m* has been dropped down the shaft to some radial position $r < R_E$ from the center, where R_E is the radius of Earth. What is the vector sum of the forces exerted on the object by all of Earth's mass that lies at any distance $d > r$ from the center? $d < r$ from the center?) ●●●



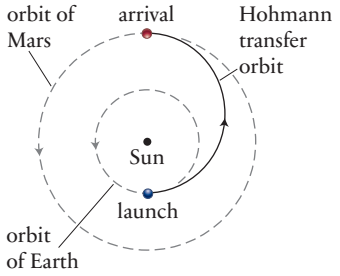
13.6 Gravitational potential energy

36. The Earth has a mass of 5.972×10^{24} kg, while the Moon has a mass of 7.348×10^{22} kg. Calculate the gravitational potential energy of the Earth-Moon system when the distance between the two bodies is 3.844×10^5 km. ●
37. The asteroid known as Toro has a radius of about 5.0 km and a mass of 2.0×10^{15} kg. Could a 70-kg person standing on its surface jump free of Toro? ●
38. (*a*) How much gravitational potential energy does a system comprising a 150-kg object and the Moon have if the object is one Moon radius above the ground? (*b*) How far should this object be from the moon for the gravitational potential become zero? ●●
39. An object 1 of mass m_1 is separated by some distance *d* from an object 2 of mass $2m_1$. An object 3 of mass m_3 is to be placed between them. If the potential energy of the three-object system is to be a maximum (closest to zero), should object 3 be placed closer to object 1, closer to object 2, or halfway between them? ●●
40. Two particles, each of mass *m*, are initially at rest very far apart. Obtain an expression for their relative speed of approach at any instant as a function of their separation distance *d* if the only interaction is their gravitational attraction to each other. ●●
41. Consider an alternate universe in which the magnitude of the attractive force of gravity exerted by Earth on a meteor of mass m_m approaching Earth is given by $F = Cm_m m_E/r^3$, where *C* is some positive constant and *r* is the center-to-center distance between Earth and the meteor. (*a*) How much work is done by the gravitational force on the meteor as it falls from very far away (infinite distance) to some height *h* above Earth's surface? (*b*) If the meteor is moving very slowly when it is very far away, how fast is it moving when it gets to that height? ●●
42. Derive expressions for the orbital speed and energy for a satellite of mass m_s traveling in a circular orbit of radius *a* around a planet of mass $m_p \gg m_s$. ●●
43. What maximum height above the surface of Earth does an object attain if it is launched upward at 4.0 km/s from the surface? ●●
44. (*a*) Derive an expression for the energy needed to launch an object from the surface of Earth to a height *h* above the surface. (*b*) Ignoring Earth's rotation, how much energy is needed to get the same object into orbit at height *h*? ●●
45. A spacecraft propelled by a solar sail is pushed directly away from the Sun with a force of magnitude C/r^2, where *C* is a constant and *r* is the spacecraft-Sun radial distance. The craft has a mass of 5.0×10^4 kg and starts from rest at a distance $r_i = 1.0 \times 10^8$ km from the Sun. What must the numerical value and units of *C* be in order for the craft to have a speed of 0.10*c* when it is very far from the Sun? (Hint: $c = 3.00 \times 10^8$ m/s.) ●●
46. In 1865, Jules Verne wrote a story in which three men went to the Moon by means of a shell shot from a large cannon sunk in the ground. (*a*) What muzzle speed must the cannon have in order for the shell to reach the Moon? (*b*) If the acceleration was constant throughout the muzzle, how long would the muzzle need to be in order to achieve this speed without exposing the men to an acceleration greater than 6*g*? (*c*) Argue whether this launch method is practical or not. ●●
47. The center-to-center distance between a 200-g lead sphere and an 800-g lead sphere is 0.120 m. A 1.00-g object is placed 0.0800 m from the center of the 800-g sphere along the line joining the centers of the two spheres. (*a*) Ignoring all sources of gravitational force except the two spheres, calculate the gravitational force exerted on the object. (*b*) Determine the gravitational

potential energy per gram at the position of the object. (*c*) How much work is needed to keep the object from getting closer than 0.0400 m from to the 800-g sphere? ●●

48. Derive an expression for the gravitational potential energy of a system consisting of Earth and a brick of mass m placed at Earth's center. Take the potential energy for the system with the brick placed at infinity to be zero. ●●●
49. Is approximating the gravitational potential energy near the surface of the Sun as $mg_S\Delta x$ accurate over a smaller or larger range of values than approximating the gravitational potential energy near the surface of Earth as $mg_E\Delta x$? ●●●
50. A uniform rod of mass m_{rod} and length ℓ_{rod} lies along an x axis far from any stars or planets, with the center of the rod at the origin (Figure P13.50). A ball of mass m_{ball} is located at position x_{ball} on the axis. (*a*) Write an expression for the gravitational potential energy of the system made up of the ball and a small element dm_{rod} of the rod located at position x_{dm}. (*b*) Integrate your expression over the length of the rod to determine the potential energy of the system for $x_{ball} > \ell_{rod}/2$. (*c*) It can be shown that for such a system the gravitational force exerted by the rod on an object located a distance x from the origin is $F_x = -dU/dx$. Using this relationship, compute the force exerted by the rod on the ball at any distance x from the rod center. ●●●

Figure P13.50



13.7 Celestial mechanics

51. The parabolic orbit of any comet around the Sun might be described as a collision between the two objects. Would it be better described as an elastic collision or an inelastic collision? ●
52. Assume a particle is located at the surface of the Sun. (*a*) If the particle has mass m, how fast must it be moving away from the Sun's center of mass to escape the gravitational influence of the Sun? (*b*) At what speed must a particle of mass $2m$ move in order to escape the Sun's gravitational influence? ●
53. What is the speed of a space probe when it is very far from Earth if it was launched from the surface of Earth at twice its escape speed? ●
54. Which trip takes more rocket fuel: from Earth to the Moon or from the Moon to Earth? ●●
55. A satellite moves at speed v in very low orbit about a moon that has no atmosphere. You launch a projectile vertically from the same moon's surface at the same speed v. To what height does it rise? ●●
56. A satellite in an elliptical orbit around Earth has a speed of 8032 m/s when it is at perigee, the position in the orbit closest to Earth. At this position, the satellite is 112 km above Earth's surface. How far above the ground is the satellite when it is at apogee, the position in its orbit farthest from Earth? ●●
57. A certain comet comes in on a parabolic approach around the Sun. Its perihelion is about the same distance from the Sun as the orbit of Mercury. How much faster than Mercury (expressed as a ratio) is the comet traveling at perihelion? ●●
58. Show that for circular orbits of two objects about their center of mass, $E = \frac{1}{2}U = -K$. This is a special case of the more general mathematical statement known as the *virial theorem*. ●●
59. An attractive central force exerted on a particle of mass m causes the particle to travel in a bound orbit. The orbit is elliptical with semimajor axis a, and the force has magnitude Cm/r^2, where C is a constant and r is the orbit radius. If the particle's speed is $v = \sqrt{C/2a}$ when it is farthest from the source of the force, what is its speed when it is nearest the force source? ●●
60. A particle is leaving the Moon in a direction that is radially outward from both the Moon and Earth. What speed must it have to escape the Moon's gravitational influence? ●●
61. A meteoroid passes through a position in space where its speed is very small relative to Earth's and it is at a perpendicular distance of 19 Earth radii above Earth's surface. The meteoroid is moving in such a way that Earth captures it. What is the speed of the meteoroid when it is one Earth radius above the ground? ●●
62. A space probe can be either launched at escape speed from Earth or transported to a "parking orbit" above Earth and then launched. (*a*) If the parking orbit is 180 km above Earth's surface, what is the escape speed from the orbit? (*b*) What launch speed is required to have the probe escape Earth if it is launched from the ground? ●●
63. Two identical stars, each of mass 3.0×10^{30} kg, revolve about a common center of mass that is 1.0×10^{11} m from the center of either star. (*a*) What is the rotational speed of the stars? (*b*) If a meteoroid passes through the center of mass, perpendicular to the orbital plane of the stars, how fast must the meteoroid be going if it is to escape the gravitational attraction of the stars? ●●
64. Kepler's third law says that the square of the period of any planet is proportional to the cube of its mean distance from the Sun. Show that this law holds for elliptical orbits if one uses the semimajor axis as the mean distance. (Said another way, orbits that have the same energy but different angular momentum have the same period.) ●●●
65. Two celestial bodies of masses m_1 and m_2 are orbiting their center of mass at a center-to-center distance of d. Assume each body travels in a circular orbit about the center of mass of the system, and derive the general Newtonian form of Kepler's third law: $T^2 = 4\pi^2 d^3/G(m_1 + m_2)$. ●●●
66. To travel between Earth and any other planet requires consideration of such things as expenditure of fuel energy and travel time. To simplify the calculations, one chooses a path such that the position in Earth's orbit where the launch occurs and the position in the other planet's orbit when the spacecraft arrives define a line that passes through the Sun, as shown for an Earth-Mars transfer in Figure P13.66. The path the spacecraft travels is an ellipse that has the Sun at one focus. Such a path is called a Hohmann transfer orbit, and the major axis of the ellipse, $2a$, is the sum of the radii of the Earth's and the other planet's orbits around the Sun. Take $m_S = 1.99 \times 10^{30}$ kg, $m_M = 6.42 \times 10^{23}$ kg, $m_E = 5.97 \times 10^{24}$ kg, $a_E = 1.50 \times 10^{11}$ m, and $a_M = 2.28 \times 10^{11}$ m, and assume the planets have circular

orbits. (*a*) What is the energy of the system comprising the Sun and a 1000-kg space probe in a Hohmann transfer orbit? (*b*) What is the speed of the probe in this orbit, as a function of r, the probe's radial distance from the Sun? (*c*) What is the probe's speed relative to the Sun as the probe enters the transfer orbit? (*d*) What is its speed relative to the Sun as it approaches Mars? (*e*) Given that the orbital speed of Earth is about 2.98×10^4 m/s, how much additional speed does the probe need to begin the transfer orbit? (*f*) What is the required launch speed from Earth's surface for a probe traveling to Mars in a Hohmann transfer orbit? •••

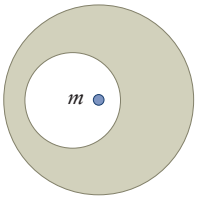


Figure P13.66

13.8 Gravitational force exerted by a sphere

67. A small disk of mass m is at the center of a larger disk that has an off-center hole drilled in it (Figure P13.67). What is the direction of the gravitational force exerted by the larger disk on the small one? •

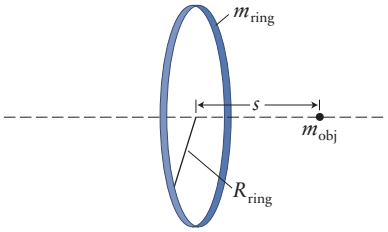

Figure P13.67

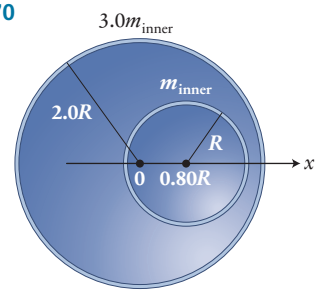
68. Is Eq. 13.37 for the gravitational force exerted by a solid sphere of mass m_s on some object of mass m_o when the two are a radial distance r apart, $F_{so}^G = Gm_o m_s/r^2$, valid for a sphere whose mass is not distributed uniformly? •



69. A uniform ring of mass m_{ring} and radius R_{ring} is shown in Figure P13.69. A small object of mass m_{obj} sits a separation distance s from the ring on the line that is perpendicular to the plane of the ring and passes through the ring's center. Obtain an expression (in terms of the given variables and universal constants) for the magnitude of the gravitational force exerted by the ring on the object. ••

Figure P13.69

70. Two uniform spherical shells are located such that their centers are along the x axis in Figure P13.70. The inner shell has mass m_{inner} and radius R, and its center is at $x = 0.80R$. The outer shell has mass $3.0m_{inner}$ and radius $2.0R$, and its center is at $x = 0$. What is the magnitude of the vector sum of the gravitational forces exerted by these two shells on an object of mass m_{obj} placed (*a*) at $x = 3.0R$, (*b*) at $x = 1.9R$, and (*c*) at $x = 0.90R$? ••

Figure P13.70

71. A thin disk of radius R has mass m_{disk} uniformly distributed over its area. (*a*) Derive an expression for the magnitude of the gravitational force this disk exerts on a particle of mass m_{part} located a distance y directly above the center of the disk. (*b*) If $y \gg R$, show that this expression reduces to that for two particles. •••

Additional Problems

72. In a system of N particles, how many terms are there in the expression for the gravitational potential energy of the system? •

73. You equip a rocket with enough fuel to reach escape speed from Earth. If you plan to launch the rocket from just above ground level, does it matter whether you launch it vertically, at an angle, or horizontally? •

74. What is the value of the acceleration g_{Venus} due to gravity at the surface of Venus? •

75. Is there any position in the elliptical orbit of a satellite where the tangential component of the acceleration is greater than the component perpendicular to the tangential component? If so, what conditions on the orbit must there be for such a position to exist? ••

76. The *gravitational vector field* $\vec{g}(\vec{r})$ is defined as the gravitational force exerted on a small object located at a particular position $\vec{r}$ divided by that object's mass. (*a*) Sketch the gravitational vector field produced by Earth at a sampling of positions around Earth. Make sure your vector lengths indicate the correct relative sizes. (*b*) Express the gravitational force exerted by Earth on an object of mass m_{obj} located a distance r_{obj} ($> r_E$) from Earth's center in terms of Earth's gravitational vector field. ••

77. Some writers of fiction have placed human beings on asteroids or other "planetoids" whose radius, in the illustrations accompanying the stories, seems not too much greater than the height of the people themselves! What would the density of such a celestial body have to be for the human to feel a gravitational attraction numerically equal to the attraction we feel to Earth? ••

78. You wish to put a satellite in orbit around Earth. (*a*) Which takes more energy per kilogram of satellite: launching the satellite from the ground to a height of 1600 km above the ground or placing the satellite into orbit once it has reached that altitude? (*b*) Repeat for an orbit 3200 km above the ground. (*c*) Repeat for an orbit 4800 km above the ground. ●●

79. Unable to sleep, you crawl out of bed one evening and stare out your window at the night sky, finding Jupiter and sitting back to contemplate its grandeur. Remembering your physics, you imagine yourself at some height above the apparent surface of Jupiter, experiencing a gravitational force that has a magnitude equal to the magnitude of the gravitational force you experience at the surface of Earth. ●●● CR

80. After seeing an old movie, you become concerned about a large asteroid that could be gravitationally attracted to Earth from very far away. You realize that long ago such an asteroid's speed relative to Earth's might have been very small, and thus you are able to calculate the relative speed it has at any separation distance from Earth. In order to get a baseline, you assume that the only object exerting a gravitational force on the asteroid is Earth, and you ignore the speed of Earth in its path around the Sun. What worries you is that observers might not sight the asteroid until it passes the imaginary line defining the Moon's orbit around Earth, and how little time that would give humanity to react. ●●● CR

81. You are working on a project to plot the course of a spy satellite. The satellite has a polar orbit (which means it passes over both of Earth's poles during each orbit), and it is outfitted with a camera carrying a wide-angle lens that can "see" strips of land up to 2500 km wide. The enemy is believed to have chosen an elevation of orbit that just guarantees complete coverage of Earth each day by these surveillance strips. You cannot avoid or block the satellite unless you know where it is. ●●● CR

82. While helping an astronomy professor, you discover a binary star system in which the two stars are in circular orbits about the system's center of mass. From their color and brightness, you determine that each star has the same mass as our Sun. The orbital period of the pair is 24.3 days, based on the oscillation of brightness observed as one star occludes (hides) the other. From this information you are able to ascertain the distance between the stars. ●●● CR

83. Scientists still are not entirely sure whether the universe is open (which means it will keep expanding forever) or closed (which means it will eventually fall back in on itself in a "Big Crunch"). What determines whether it is open or closed is basically the same thing we calculate to determine escape speeds. Assume that the universe has a uniform density ρ. Then the mass contained in some spherical volume of space of radius R is $\frac{4}{3}\pi R^3\rho$. Model a galaxy located at the edge of this spherical volume as a particle and consider its energy. According to Hubble's law, the speed of this galaxy is HR, where $H = 2.2 \times 10^{-18}\ \text{s}^{-1}$ is called the Hubble constant. (*a*) What is the maximum density of the universe such that it does not close? (*b*) The current estimate of the density of the universe is $10^{-26}\ \text{kg/m}^3$, including about 25% *dark matter,* which is matter we cannot observe directly, and 70% *dark energy*, another constituent that is not directly observable. Both dark matter and dark energy contribute to gravity, though, and so are included in the density estimate. Compare this value with your result and discuss what difference it would make if there were no dark matter in the universe. ●●●

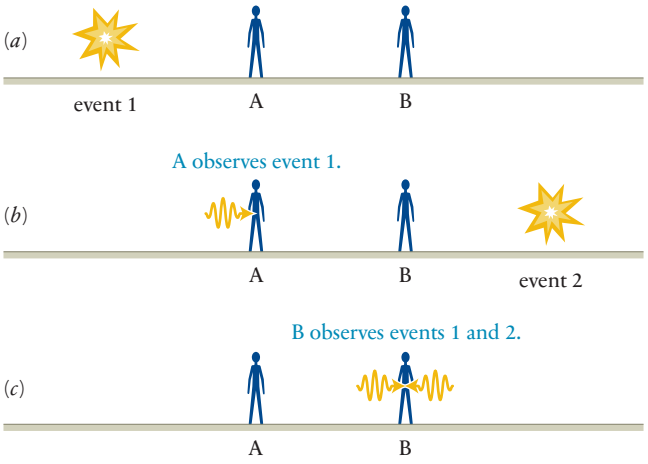
CONCEPTS

QUANTITATIVE TOOLS

Time is the basic fabric of life because living means *changing* and change—a concept central to all we have discussed up to now—cannot exist without time. Time is so basic that we take for granted that we all agree on what it is. If, for instance, you and I arrange to meet here tomorrow at three o'clock and we make sure our watches agree now, we expect to see each other here tomorrow when our watches read three o'clock.

As we see in this chapter, however, our commonsense experience of time fails to explain certain experimental observations. In 1905 Albert Einstein realized these shortcomings and revised the basic notions of space and time with his *theory of special relativity*. The basic principles of this theory are the principle of relativity, which we discussed in Chapter 6, and the experimental fact that the measured value of the speed of light is independent of the motion of the source relative to the observer making the measurement. The revised notions of space and time require us to adjust our understanding of inertia, momentum, and energy. However, the conservation principles—the unifying principles of this text and the most fundamental laws of physics—continue to hold, as required by the principle of relativity.



14.1 Time measurements

Since the advent of clocks, the measurement of time has been so straightforward that it hardly requires much thought. Just as spatial coordinates determine *where* something happens, time tells us *when* it happens. Let's define an **event** as something that happens at a specific location at a specific instant. Take, for example, your act of reading this sentence. If you and I agree on a coordinate grid (for example, longitude, latitude, and altitude) and a time zone, you can specify the location and time of this event in such a way that it is uniquely and precisely defined. You are reading this sentence, say, in Helena, Montana (46.595°N, 112.030°W, alt. 1138 m), at 9:33 p.m. today.

Let's concentrate for now on the time part of describing events. By referring to the watch on your wrist, you can measure the instant at which any event near you occurs. There are two reasons you can count on this procedure to work. First, it is possible to construct a device—a clock—that measures equal, calibrated time intervals (say, seconds). Clocks serve as a "ruler" for time, just as an ordinary ruler helps us measure space. Second, we can *synchronize* clocks; that is, we can make sure two clocks run at the same rate and their readings agree.

Keeping time helps us sort out the sequence of events and establish a possible causal relationship between events (see Section 1.4). If you are at the location of two successive events, it's straightforward to determine which event happened first and what the time interval between them is. How, though, can you determine the sequence for two events that occur at different locations?

Figure 14.1 Two observers with synchronized clocks observe two events.

We need to be able to detect some sort of signal (such as sound or light) to observe an event, and all such signals travel at some finite speed. Of all signals known, light travels the fastest and therefore is the most convenient for timing events.

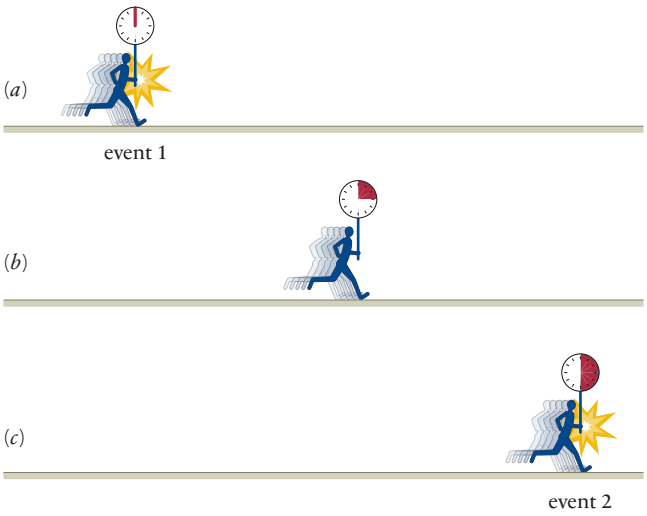


Figure 14.1 shows two events—the emission of light signals at two locations—and their observation by two observers using synchronized clocks. The light signals are of short duration, like a flash, so that we can consider each emission to take place at a definite instant. The signals travel at the speed of light (3.00×10^8 m/s in vacuum or air) and carry the message that the event has occurred. Observer A is closer to event 1 than to event 2; observer B is closer to event 2 than to event 1. In Figure 14.1*a*, event 1 occurs but the signal has not yet reached either observer. In Figure 14.1*b*, the signal from event 1 reaches observer A and event 2 occurs. Note that the signal from event 1 has not yet reached observer B and that the signal from event 2 has reached neither observer. A little later, the signals from both events reach observer B (Figure 14.1*c*) but the signal from event 2 has not yet reached observer A.

14.1 In Figure 14.1, based on the time of arrival of the light signals, which event is observed first according to (*a*) observer A and (*b*) observer B?

As this checkpoint shows, if you go by the instants at which the signals reach the two observers, the observers do not agree on the sequence of the two events. Observer A sees the events as occurring at two different instants, but observer B sees them as occurring at the same instant. The instant of *observation*, however, is not the instant at which the light signals *are emitted*. For events that occur around you in daily life, the difference between the instant each event happens and the instant you observe it is negligible because light travels so fast. Light emitted by the Sun, however, takes about 8 minutes to reach us. Thus, if a solar flare occurs at the surface of the Sun, that event takes place

CONCEPTS

Figure 14.2 One way to measure the time interval between two events is to travel from one event to the other, using a single clock to record the instant at which each occurs.

8 minutes before we observe it. Light emitted by the Andromeda Galaxy takes 2 million years to reach Earth. If you look at the Andromeda Galaxy on a dark, moonless night, you see the light it emitted 2 million years ago. A lot could have happened to that galaxy in those 2 million years—for all you know, the entire galaxy might not be there anymore!

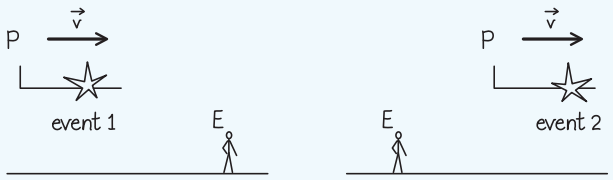
Even though we do not deal with these astronomical distances here in our discussion of time measurements, we still need to take into account the *signal delay* between event and observation. This signal delay is the time interval it takes for the signal to travel from the location of the event to the location of the observer. For nearby events, the signal delay is negligible. For events separated by an appreciable distance, we can avoid signal-delay complications in several ways. One straightforward, if not always practical, way is shown in **Figure 14.2**: An observer travels from the location of event 1 to the location of event 2 and records the two events on the same clock. In the observer's reference frame, the two events take place *at the same location* (the origin if you imagine axes attached to the observer) but at different instants. To avoid the complications of a noninertial reference frame (see Chapter 6), the observer should travel at constant velocity. The time interval obtained this way is called the **proper time interval:***

> **The time interval between any two events that occur at the same position in a particular reference frame is called the proper time interval between the two events.**

Not all pairs of events are separated by a proper time interval: If an observer does not have enough time to travel from the first event to the second event to observe both events at his location, there is no proper time interval for those events.

*From the French *propre* meaning *own*, as in one's "own time."

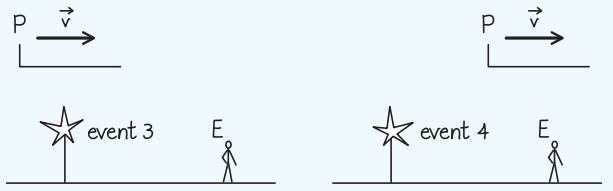
EXAMPLE 14.1 Proper time interval



You are flying in a plane, and a friend is on the ground. Which of you measures the proper time interval between (*a*) the beginning and end of a brief in-flight video program and (*b*) two successive signals from a warning light on a tall building along your flight path?

1 GETTING STARTED The problem involves two observers (my friend and I) and two pairs of related events. My friend is in the Earth reference frame (E); I am in the reference frame of the plane (P). To simplify the discussion, I denote the beginning and end of the movie as events 1 and 2, respectively, and the two successive flashes of the warning light as events 3 and 4.

2 DEVISE PLAN To see who measures the proper time interval, I should make a sketch for each pair of events, showing the positions of the E and P reference frames. If either observer sees either pair of events as occurring at the same location, that observer measures the proper time interval.



3 EXECUTE PLAN (*a*) **Figure 14.3** shows that the beginning (event 1) and end (event 2) of the video program take place at the same location in reference frame P. Because that is my reference frame, I measure the proper time interval between these events. Figure 14.3 also shows that to my friend, standing at one location in the Earth reference frame, the two events happen at different locations (event 1 high and to his left, event 2 high and to his right). Thus he cannot measure the proper time interval. ✔

Figure 14.3

(*b*) **Figure 14.4** shows that the two flashes take place at the same place in reference frame E. Because this is my friend's reference frame, he measures the proper time interval between the two flashes. As for me, I see the first flash as coming from right below the plane but the second flash as coming from behind the plane. Two different locations from my point of view mean that I cannot measure the proper time interval between the flashes. ✔

Figure 14.4

4 EVALUATE RESULT The video "happens" in the plane, so the plane is the reference frame in which to measure the proper time interval—the screen on which the video is projected is at rest in the plane. Likewise, the warning light is at rest in the Earth reference frame. My answers make sense.

CONCEPTS

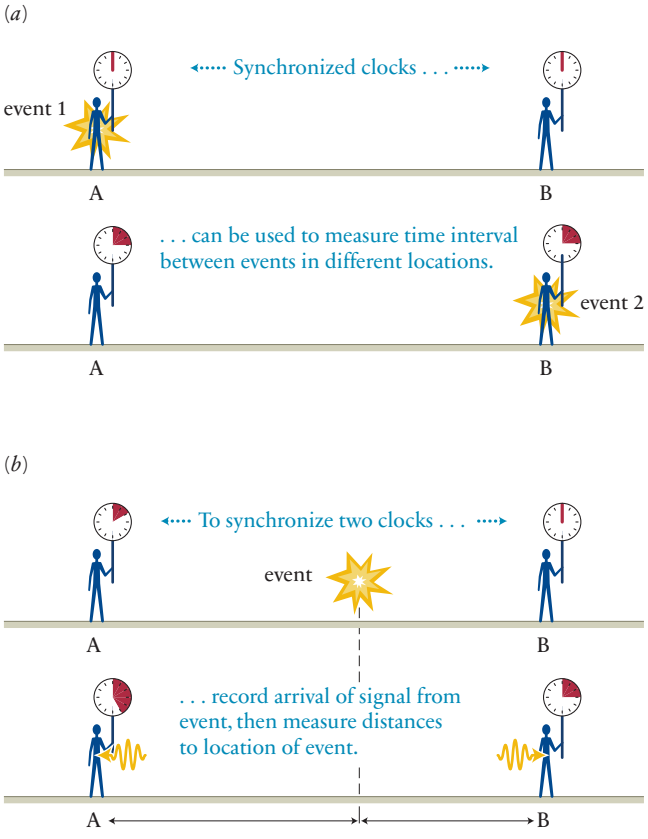
Because measuring a proper time interval is not always practical, another way to measure the time interval between events that occur in two locations is to place observers with identical clocks near each event, so that each observer can record the nearby event according to his clock (**Figure 14.5a**). Once the events are over, the two observers can communicate their clock readings and determine which event occurred first.

To synchronize the clocks, the observers can use the procedure illustrated in Figure 14.5*b*. An event sends out light signals to both observers, and each observer records the instant at which the signal reaches his clock. They then measure the distance from each clock to the location of the event and correct for the signal delay. If the clocks are synchronized, the observers obtain the same instant for the event after they subtract the signal delay from their recorded clock reading. If they don't obtain the same instant, they can use this procedure to adjust their clocks.

Because we don't always know where events are going to occur, it makes sense to construct a reference frame that has identical clocks arranged in a grid at regular fixed spacings, as shown in **Figure 14.6**. We can synchronize the clocks by sending a signal from the clock at the origin (the *reference clock*) to all the other clocks and correcting each clock's reading for the signal delay. We can then define the instant in that reference frame at which any event occurs as the reading on the clock whose position coincides with that event. From now on, when we say "measuring the instant at which an event occurs in a given reference frame," we shall understand this to mean that we are using this procedure and that *an observer* in this reference frame is the observer stationed at the clock nearest the event.

Now that we have established a procedure for determining the instant at which an event occurs in a certain reference frame, we can determine the order of events in that reference frame. Two events that occur at different positions in the reference frame are **simultaneous** when the readings of the two clocks at the two locations of the events are identical. When the events are not simultaneous, the clock readings at the locations of the events allow us to determine the sequence of the events.

Figure 14.5 Synchronized clocks can be used to measure the time interval between events that occur in different locations. (*a*) Each observer records the instant at which a nearby event occurs. (*b*) To synchronize their clocks, the two observers record the instant at which a single event occurs.



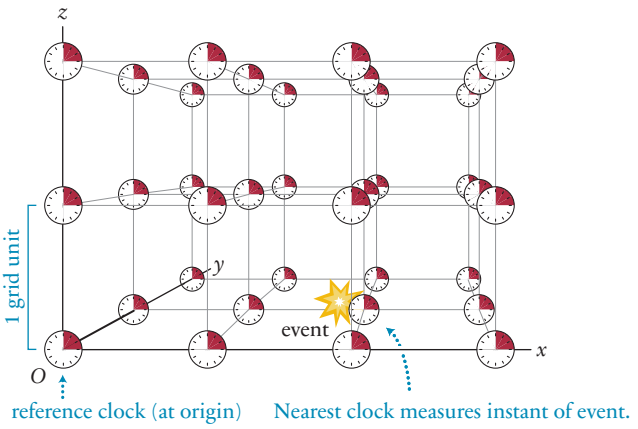


Figure 14.6 The scaffold of time: a reference frame made up of a grid of synchronized clocks. An event can occur anywhere in the grid, and the instant at which the event occurs is the instant shown on the clock nearest the event.

EXERCISE 14.2 Synchronizing clocks

Suppose you want to synchronize the network of clocks in Figure 14.6 by emitting a single light pulse at the origin. This signal triggers each clock to start running from some initial setting. If it takes the signal 1 s to travel along one grid unit and if the reference clock is set initially to 12 o'clock, what should the initial settings be for each clock (*a*) along the x axis and (*b*) along the diagonal in the $y = 0$ plane?

SOLUTION (*a*) Along the x axis, the signal arrives at the first clock to the right of the reference clock 1 s after the emission, when the reference clock reads 12:00:01, and so I set the first clock to 12:00:01. The next clock along the x axis starts running when the signal triggers it at 12:00:02, and so I set each clock on the x axis 1 s ahead of the clock immediately to its left. ✔

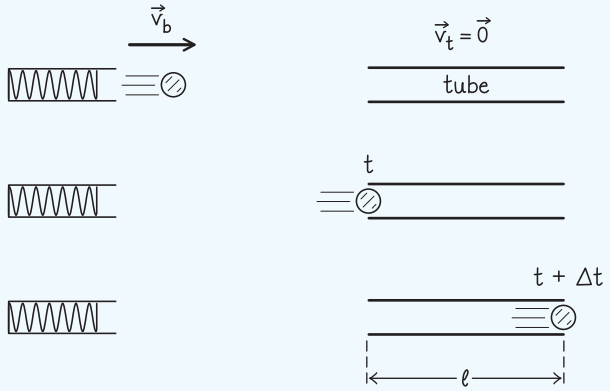
CONCEPTS

(*b*) The light must travel $\sqrt{2}$ grid units to reach the first clock along the diagonal. We must therefore set that clock ahead of the reference clock by $\sqrt{2}$ s = 1.4 s. The next clock along the diagonal is set ahead by $2\sqrt{2}$ s, and so on. ✔

14.2 Suppose an observer is standing at the origin in Figure 14.6 and all the clocks are synchronized. (*a*) Which of the following is true? The observer sees that (*i*) all the clocks read the same time, (*ii*) nearby clocks display later times than more distant clocks, (*iii*) nearby clocks display earlier times than more distant clocks. (*b*) Does the observer see all the clocks running at the same rate?

14.2 *Simultaneous* is a relative term

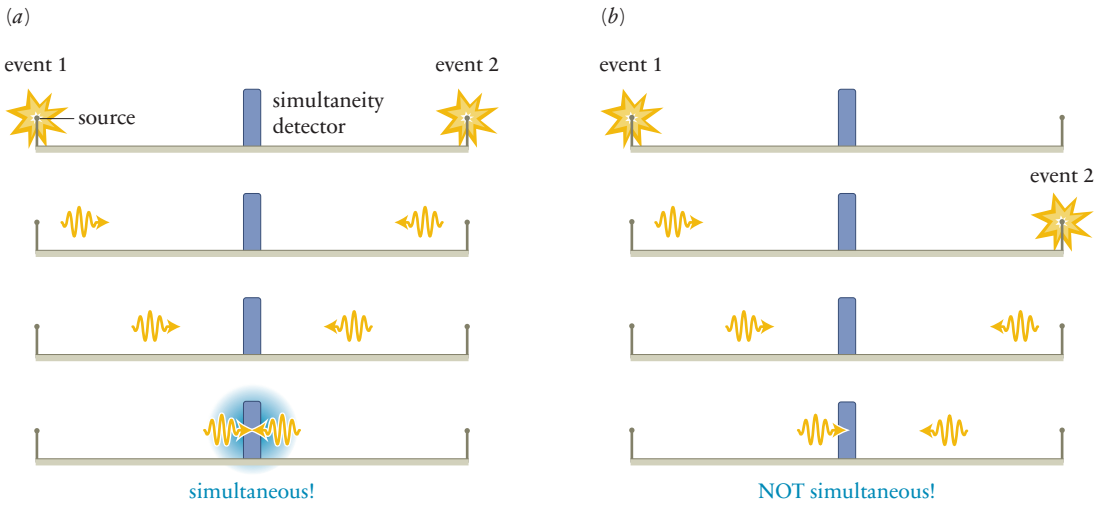
Suppose we determine that two events—for example, the emission of light signals by two sources—are simultaneous in a certain reference frame. Are these events also simultaneous in another reference frame that is in motion relative to the first? To help answer this question, we use a *simultaneity detector*: a device that emits a blue light when it receives two signals at the same instant.



When we position the detector midway between the positions where the two events take place, as illustrated in **Figure 14.7**, the time interval it takes to travel to the detector is the same for both signals. This means that, if the two signals reach the detector at the same instant and the blue light comes on, the events were simultaneous in the reference frame of the detector (Figure 14.7*a*). If the events occur at different instants, the two signals do not arrive at the detector at the same instant and the blue light does not come on (Figure 14.7*b*). The blue light thus tells us whether or not the two emission events were simultaneous *in the reference frame of the detector*. One advantage of this device is that we do not need to be in the reference frame of the detector to determine whether the two events are simultaneous in its reference frame. As long as the simultaneity detector is placed midway between the two events, the blue light tells us whether the events are simultaneous in the detector's reference frame.

Up to now we have discussed only measurements made by an observer (or detector) at rest with respect to the sources of the signals. What happens to the transmission of signals when the source and observer are moving relative to each other? To find out, let's start by reviewing the relativity of speeds for everyday objects that move much more slowly than light.

EXAMPLE 14.3 Fast ball



Consider a spring-loaded device that ejects a ball at some unknown everyday speed v_b. To measure this speed, you measure the time interval it takes the ball to pass through a stationary tube of known length ℓ (**Figure 14.8**). Now suppose the tube is moving at speed v_t toward the ejection device. What speed do you obtain by dividing the length ℓ of the tube by the time interval Δt it takes the ball to pass through the tube? Express your answer in terms of v_b and v_t.

Figure 14.8 Example 14.3.

(Continued)

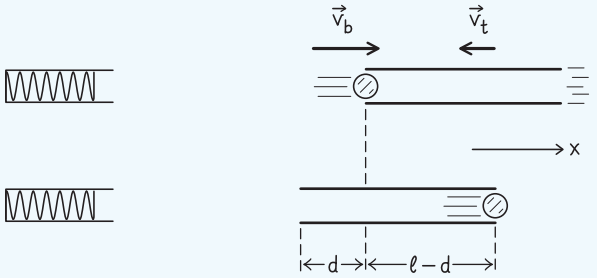


Figure 14.7 A detector located midway between two light sources can detect whether signals are emitted (*a*) simultaneously or (*b*) not simultaneously.

CONCEPTS

1 GETTING STARTED I begin by drawing the ball at the instant it enters and the instant it exits the moving tube (**Figure 14.9**). I choose my positive x axis to be in the direction of the ball's motion and use d to denote the distance the tube moves while the ball passes through. The distance the ball travels as it passes through the tube is thus $\ell - d$.

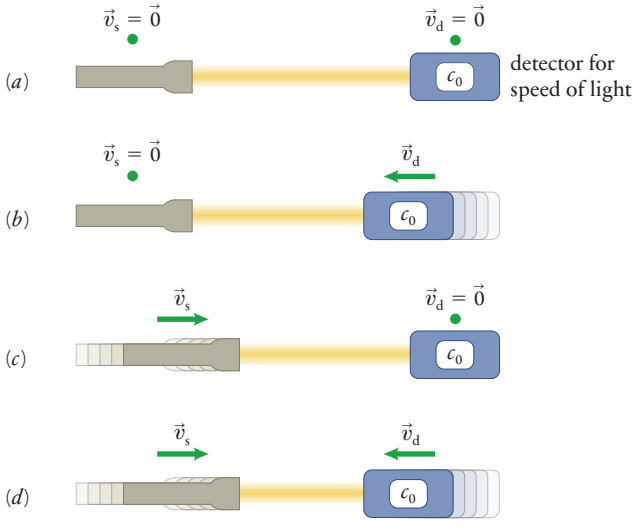
Figure 14.9

2 DEVISE PLAN From my sketch I see that during the time interval Δt, two things happen: The tube advances a distance d, and the ball travels a distance $\ell - d$. Because speed equals distance traveled divided by the time interval needed to travel this distance, I can relate these two distances to the speeds v_b and v_t. This gives me two equations, from which I can solve for the two unknowns d and Δt. I also note that dividing ℓ by Δt gives me the speed v_{Mb}, which is the speed of the ball measured by an observer M moving along with the tube.

3 EXECUTE PLAN Because the tube advances a distance d in the time interval Δt, I have $v_t = d/\Delta t$. Likewise, for the ball: $v_b = (\ell - d)/\Delta t = \ell/\Delta t - d/\Delta t$. The first term equals the speed v_{Mb} I am asked to determine. The second term is the speed of the tube v_t, and so $v_b = v_{Mb} - v_t$. Rearranging terms, I get $v_{Mb} = v_b + v_t$. The speed of the tube is added to that of the ball. ✔

4 EVALUATE RESULT Using the subscript cancellation rule (Eq. 6.14), I can write $\vec{v}_{Mb} = \vec{v}_{ME} + \vec{v}_{Eb}$. With my choice of positive x axis to the right in Figure 14.9, I get $v_{Mbx} = v_{MEx} + v_{Ebx}$. Because $\vec{v}_{ME}$ is the velocity of Earth relative to an observer moving with the tube, I have $v_{MEx} = v_t$. Likewise $\vec{v}_{Eb}$ is the velocity of the ball relative to Earth, and so $v_{Ebx} = v_b$. Therefore, $v_{Mbx} = v_{MEx} + v_{Ebx} = v_t + v_b$, which confirms the result I obtained.

14.3 In Example 14.3 what is the time interval Δt it takes the ball to pass through the moving tube if $v_b = v_t = v$? Express your answer in terms of ℓ and v.



Example 14.3 reaffirms what we learned in Chapter 6: The speed of an everyday object relative to an observer depends on the motion of both the object and the observer. Relative to an observer moving along with the tube in Figure 14.9, the ball moves not at speed v_b but at speed $v_b + v_t$. Measurements of the **speed of light in vacuum,** denoted by c_0, however, show something very different:*

> **The measured value of the speed of light propagating in vacuum is c_0, independent of the motion of the source relative to the observer making the measurement.**

This counterintuitive result was first suspected after an experiment done by A.A. Michelson and E.W. Morley in 1887. Many experiments since then have provided extensive confirmation of the Michelson-Morley results. To help you grasp the full meaning of this remarkable result, imagine that we shine a beam of light from a source into a device that is at rest relative to the source and that measures the speed of light in vacuum (**Figure 14.10a**; such an apparatus exists). The result is a value of 299,792,458 m/s (see Section 1.3), which we shall round off to 3.00×10^8 m/s. If we now move the measuring device toward the source at speed v_d and measure the speed of light, we obtain not $c_0 + v_d$ but again c_0 (Figure 14.10*b*)! This baffling result is like discovering that the speed of the ball with respect to the tube in Figure 14.8 is the same regardless of the motion of the tube relative to Earth.

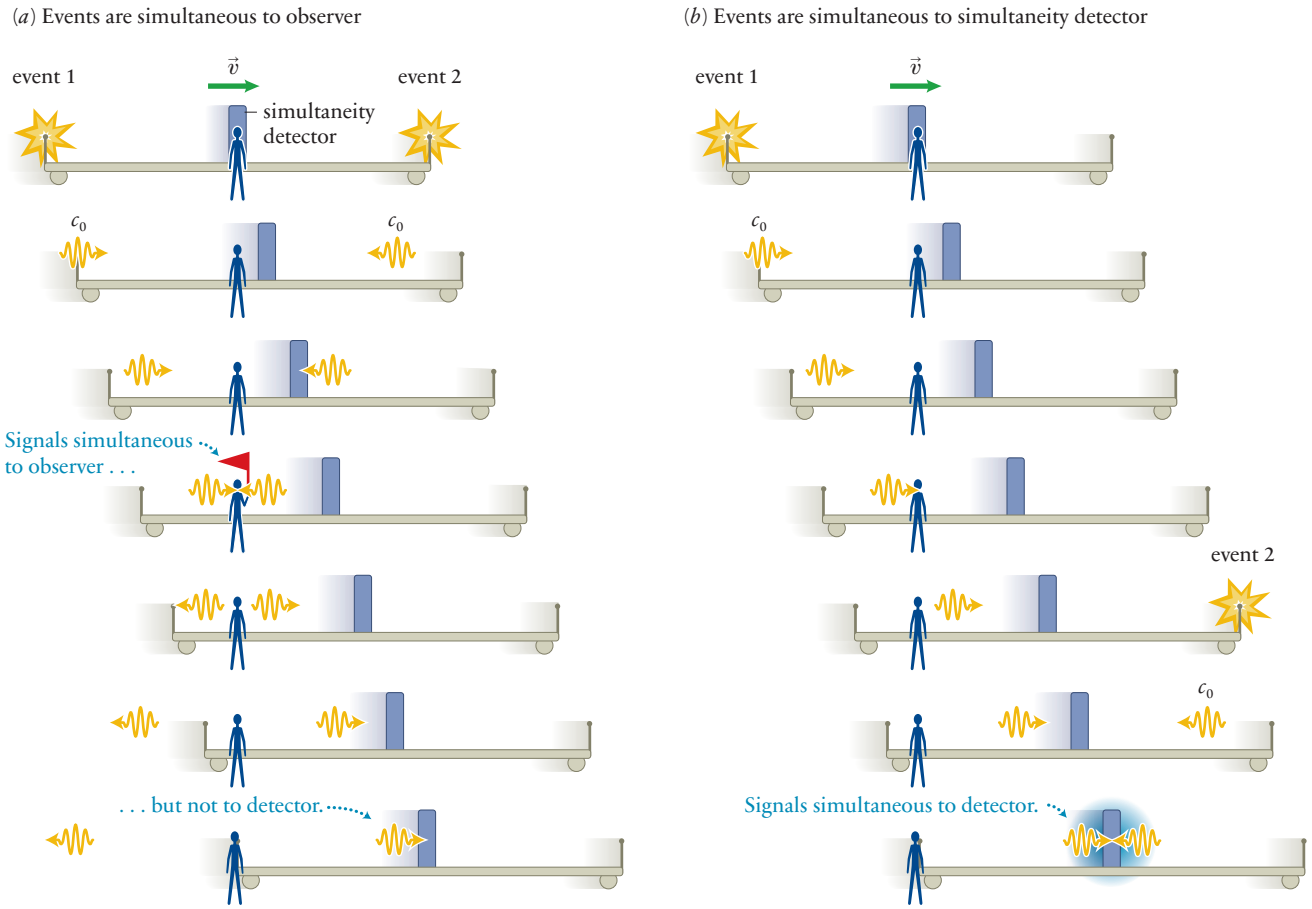
Experiments show that it makes no difference whether we move the source, move the measuring device, or move both. In all cases, the device measures the speed of light in vacuum to be c_0 (Figures 14.10*c* and *d*). This result holds even when the source or detector moves at a substantial fraction of c_0: If a source moves toward you at a speed of $0.2c_0$, you still measure the

Figure 14.10 The measured value of the speed of light in vacuum does not depend on the speeds of the source and the measuring device.

*The subscript zero on c_0 is there to remind us that this is the value obtained in vacuum. The zero indicates the absence of any medium (that is, substance) through which the light propagates.

CONCEPTS

light traveling toward you at c_0, not $c_0 + 0.2c_0 = 1.2c_0$. After more than 100 years of repeated experiments, we can most certainly rule out an error in measurement.



Any quantity whose value does not depend on the choice of reference frame is called an **invariant.** Because the speed of light is the same in all inertial reference frames, it is an invariant. Invariants play an important role in physics because we want to develop theories and laws that are the same in different reference frames. To construct these theories and laws, we first need to establish which physical quantities are invariants. The invariance of these quantities tells us something fundamental about the underlying laws of the universe.

Measuring the speed of light involves nothing more complicated than measuring the distance traveled by light in a certain time interval and dividing that distance by the time interval. The unsettling conclusion from Figure 14.10 is that measured values of distances and time intervals must somehow depend on the motions of the source and the reference frame. This conclusion forces us to reexamine what we mean by *distances* and *time intervals*, two of the most basic quantities we introduced back in Chapter 2.

Let us start with the experimental fact that the speed of light in vacuum is always exactly c_0 and examine the consequences this result has on the experiment of Figure 14.7*a*. Suppose the entire setup—the two light sources and the simultaneity detector midway between them—now moves at a very high speed v past an observer at rest on the ground, as in **Figure 14.11**. (By *very high* I mean a speed large enough for the detector to move an appreciable distance in the time interval it takes the light signals to reach the detector.) Suppose further that the observer sees the two emission events occur at the same instant; that is, he is midway between the two sources at the instant they emit a light signal, and so the two signals reach him at the same instant (middle panel in Figure 14.11*a*). In other words, *the events are simultaneous in the observer's reference frame.*

As you can see from Figure 14.11*a*, however, the simultaneity detector moves to the right as the signals travel toward it, and so it receives signal 2 before it receives signal 1. Therefore the blue light does not go on. In the reference frame of the detector, the two signals were *not* emitted simultaneously! Meanwhile, the observer is confused: In his reference frame, the two

Figure 14.11 If the sources and the simultaneity detector move together at high speed relative to an observer, then (*a*) events that are simultaneous to the observer will not be so to the detector. (*b*) To make the signals strike the simultaneity detector at the same instant, the source behind the detector must emit its signal before the source in front of the detector.

signals *were* emitted simultaneously, and so why didn't the blue detector light come on?

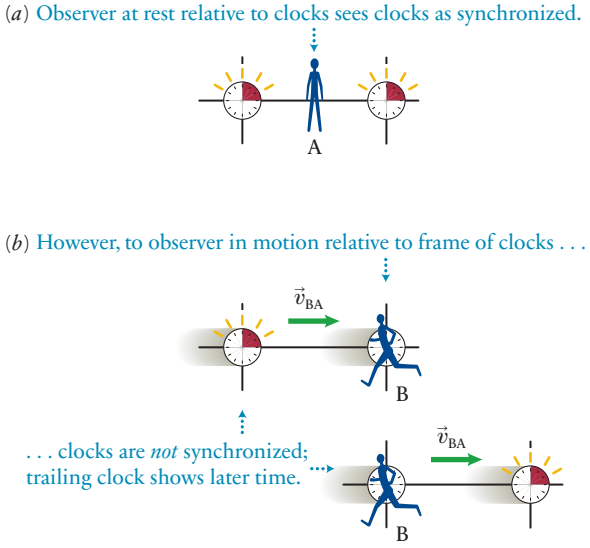
14.4 Suppose the observer in Figure 14.11*a*, at rest relative to the ground and standing midway between the two sources when they emit signals, is joined by another observer who moves along with the simultaneity detector. (*a*) Based on what the detector tells them, do the observers agree that the light signals do not reach the detector at the same instant? (*b*) How does each observer explain why the signals don't reach the detector at the same instant?

Suppose the sources in Figure 14.11 emit the signals in such a way that the fast-moving detector receives them at the same instant and the blue light turns on. To the observer at rest on the ground, source 1 must have emitted its light signal before source 2 emitted its signal because signal 1 has to catch up with the detector moving away from it (Figure 14.11*b*). In his reference frame, the two events are *not* simultaneous, and so he is once again confused by what the detector is "saying": Blue light on means the events were simultaneous. The blue light tells us that the detector sees exactly the situation depicted in Figure 14.7*a*, and so in the reference frame of the detector the emission events are simultaneous. From these experiments we infer that:

Events that are simultaneous in one reference frame need not be simultaneous in another reference frame that is moving relative to the first.

What does this relativity of simultaneity imply for the grid of synchronized clocks of Figure 14.6? To answer this question, consider a pair of synchronized clocks at rest relative to observer A midway between the two clocks in **Figure 14.12**. The clocks are mounted on opposite ends of a rod that is one grid unit long. Because the clocks are synchronized, they strike 3 o'clock at the same instant according to observer A. Now consider the situation from the point of view of observer B, who is moving to the left at constant speed relative to A.

Figure 14.12 Two synchronized clocks are unsynchronized in the reference frame of an observer moving relative to the clocks.



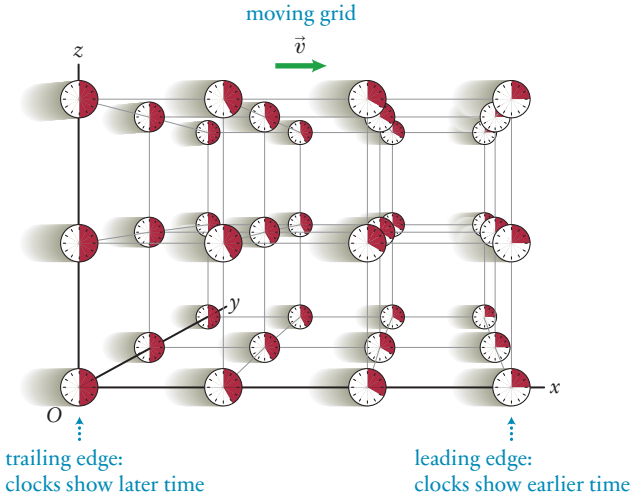


Figure 14.13 Desynchronization of time in a moving reference frame.

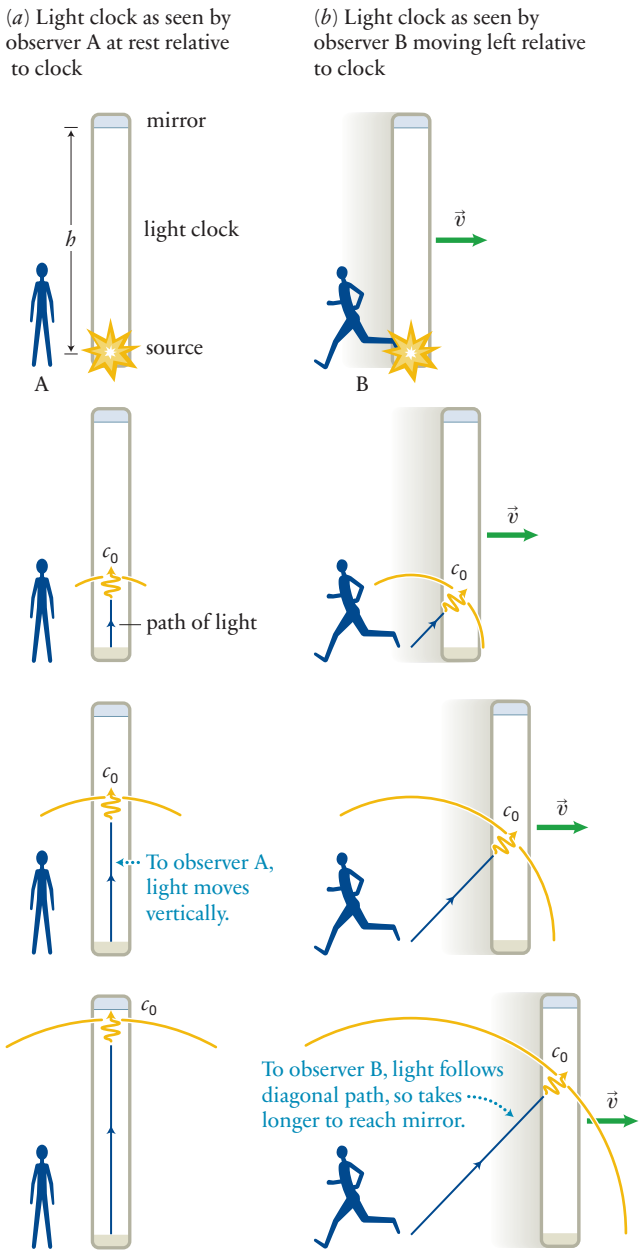
From B's perspective, the two-clock unit moves to the right, just like the simultaneity detector in Figure 14.11. Suppose events 1 and 2 in Figure 14.11 are our two clocks striking 3 o'clock. As Figure 14.11*b* shows, these two events occur at the same instant in the reference frame of the detector. Relative to observer B, however, the left clock strikes 3 o'clock (event 1) before the right clock does (event 2). So, in Figure 14.12*b*, too, the left clock strikes 3 o'clock *before* the right clock in the reference frame of observer B. In other words, the clock on the trailing end of the grid unit runs ahead of the clock on the leading end. This statement must hold true for any pair of neighboring clocks along the line of motion, which means that the clocks on a grid moving relative to an observer desynchronize as shown in **Figure 14.13**. If you were to move along with the grid, all clocks would strike, say, 3 o'clock at the same instant. If the grid moves relative to you, however, the clocks at the trailing end of the grid strike 3 o'clock before those at the leading end.

What is one instant in one reference frame is a multitude of different instants in a reference frame that is moving relative to the first reference frame. As we saw in analyzing Figures 14.11 and 14.12, events that are simultaneous in one reference frame are not simultaneous in a reference frame that is moving relative to the first one.* Simultaneity is a relative concept, and time intervals are therefore not invariants.

*The only events we consider here are ones that occur at different positions along the line of motion of two reference frames in motion relative to each other. Events occurring along an axis perpendicular to the line of motion can be simultaneous in both reference frames.

CONCEPTS

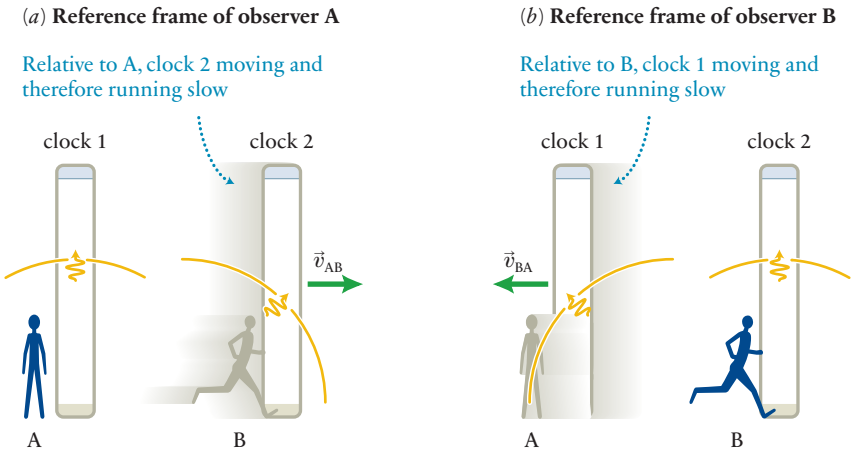
The reason this notion of the relative nature of simultaneity defies common sense is that these effects are observable only at speeds that are much greater than everyday speeds. In Figure 14.11*a*, for example, in the time interval it takes the light to travel half the distance between the two sources, the simultaneity detector travels one-fourth of that distance. In other words, the detector moves at half the speed of light, or 1.5×10^8 m/s, close to a million times faster than the speed of an airplane! Had it instead moved at the speed of an airplane, the displacement between the top and bottom pictures in Figure 14.11 would have been negligible, and so, for all practical purposes, the signals would have arrived simultaneously at the detector both according to an observer on the ground and according to one on the moving assembly. It is only when observers (or detectors) move at speeds close to c_0 relative to each other that deviations from our everyday experience cannot be ignored.



14.5 Suppose the setup in Figure 14.11 is 10 m long. (*a*) How long does it take a light signal to travel from source to detector? (*b*) If the setup moves at 20 m/s, how far does it travel in the time interval you calculated in part *a*? (*c*) By how much does the displacement of the detector shorten (or lengthen) the travel time of the light signals? (*d*) Do you expect the time interval you calculated in part *c* to be measurable? (*e*) Repeat parts *b*–*d* for a detector moving at 1.0×10^8 m/s.

14.3 Space-time

The fact that simultaneity is relative rather than absolute makes us rethink the whole concept of time. If simultaneity depends on the motion of observers relative to each other, shouldn't the rate at which a clock is observed to tick depend on the motion of the observer relative to the clock? The answer is yes, and here is the easiest way to see that. Consider the device shown in **Figure 14.14**, called a *light clock*. At the bottom is a source that emits a very short light signal; at the top is a mirror that reflects the signal back down. At the instant the reflected signal reaches the bottom, the source is triggered to emit a new light signal. The up-and-down motion of the signals determines the period of this clock. If the mirror is a distance h away from the source, it takes each light signal a time interval h/c_0 to travel from the source up to the mirror and the same time interval to travel back down to the source. The period of this clock is thus $2h/c_0$. Just as the ticking of a mechanical clock defines the unit of time for the clock, this period defines the unit of time for the light clock.



Consider this clock from the perspective of two observers: one at rest relative to the clock (observer A, Figure 14.14*a*) and one moving to the left at very high speed v relative to the clock (observer B, Figure 14.14*b*). To observer A the clock signals move straight up and down. To observer B, however, the signals move along a longer diagonal path. Because the signals travel at exactly c_0 according to both observers, observer B sees the signals take longer to travel from source to mirror and from mirror to source.

Figure 14.14 Because the speed of light in vacuum is always c_0, the light signal in a light clock takes longer to reach the mirror according to an observer moving relative to the clock than to an observer at rest relative to the clock.

CONCEPTS

Figure 14.15 Each observer sees the other observer's clock run more slowly.

14.6 (*a*) In Figure 14.14, is the period of the clock according to observer B greater than, equal to, or less than the period according to A? (*b*) Does the period of the clock according to B increase, decrease, or stay the same if we increase v?

Because the distance the signal travels from source to mirror and back to source is greater according to B than according to A, it takes longer for the clock to complete a cycle according to observer B. Therefore, the clock period is longer for B than it is for A. Observer B sees the clock as running more slowly than observer A. The greater the speed at which the clock moves relative to B, the more slowly she observes it ticking off its units of time. This effect is called **time dilation** because the units of time appear stretched out (dilated):

When a clock is in motion relative to an observer, that observer sees the time units of the clock as being longer than the time units of an identical clock at rest relative to her. Consequently, she measures the clock in motion as running slow relative to the clock at rest.

14.7 On your desk in front of you are two watches, one mechanical and one electronic. For each minute on the electronic watch, the mechanical watch advances by only 59 s. (*a*) Is the mechanical watch fast or slow relative to the electronic one? (*b*) Using the mechanical watch as the standard, is the electronic one fast or slow?

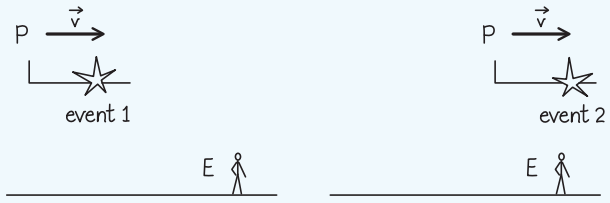
Ordinarily, if your watch runs slow relative to some clock, that clock runs fast relative to your watch, as you just saw in Checkpoint 14.7. Things are different when dealing with time dilation. Consider, for example, two identical clocks: clock 1, which is at rest relative to observer A, and clock 2, which is traveling along with observer B. To observer A, clock 2 is in motion and therefore running slow compared to clock 1 (**Figure 14.15*a***). To observer B, however, clock 2 is at rest and clock 1 is moving (Figure 14.15*b*). From B's perspective, it is now the signal in clock 1 that takes longer to reach its mirror. So to B, clock 1 appears to run slowly relative to clock 2. The effect of time dilation is thus symmetrical, as required by the principle of relativity: Each observer sees the other observer's clock run more slowly.

Note that in Figure 14.14*b* the light signal leaves the source when the clock is at one position and returns to the source when the clock is at a different position. This means that the time interval between these events measured in B's reference frame is not the proper time interval. Observer A measures the proper time interval because the emission and return take place at the same position relative to A. This means that the proper time interval between the two events is the shortest, and we can say:

An observer who measures the proper time interval between two events (that is, an observer for whom the events occur at the same location) obtains the shortest time interval between those two events.

EXAMPLE 14.4 My nap was shorter

You are flying in a plane, and a friend is on the ground. Who measures a shorter duration of (*a*) a nap you take and (*b*) a nap your friend takes?



❶ **GETTING STARTED** Like Example 14.1, this problem involves two observers (my friend and I) and two pairs of events (the beginning and end of each person's nap). My friend is in the Earth reference frame (E); I am in the reference frame of the plane (P). To simplify the discussion, I denote the beginning and end of my nap as events 1 and 2, respectively, and the beginning and end of my friend's nap as events 3 and 4, respectively.

CONCEPTS

2 DEVISE PLAN The proper time interval between two events is the shortest time interval between them. Therefore this problem boils down to determining who measures the proper time interval for each nap. I should therefore make a sketch for each pair of events.

3 EXECUTE PLAN (*a*) **Figure 14.16** shows the beginning (event 1) and end (event 2) of my nap on the plane. To me, the two events take place at the same location, which means that the time interval I measure is the proper time interval. To my friend, the two events take place at different locations (I fall asleep far to his left and wake up directly overhead), so the interval he measures is not the proper one. Thus I measure the shorter duration for my nap. ✔

Figure 14.16

(*b*) **Figure 14.17** shows the beginning (event 3) and end (event 4) of my friend's nap on the ground. To my friend, the two events take place at the same location, which means that the time interval he measures is the proper time interval. To me, the two events take place at different locations (my friend falls asleep in front and below the plane and he wakes up directly underneath), so the interval I measure is not the proper one. Thus my friend measures the shorter duration for his nap. ✔

Figure 14.17

4 EVALUATE RESULT Each nap happens in the reference frame of the napper, and so it makes sense that each person measures the proper time interval of her or his nap.

You may ask yourself if this slowing down of moving clocks is just a peculiarity of the type of clock we have constructed. Who measures time with light clocks anyway? Suppose you have two identical mechanical clocks adjusted so that their periods are the same as those of a pair of identical light clocks. Now suppose you pair each mechanical clock with one of the light clocks and set one pair in motion. The stationary pair remains synchronized. Likewise, the moving pair must remain synchronized for this reason: If the motion of the clocks caused them to become unsynchronized, an observer moving along with them would note the difference in ticking rates and from this difference be able to determine his state of motion, which would violate the principle of relativity (see Section 6.3). Indeed, no one has ever observed a pair of initially synchronized clocks becoming unsynchronized because the pair's state of motion changes. So, we know that (1) moving light clocks run more slowly and (2) mechanical clocks behave just as light clocks do. We therefore conclude that moving mechanical clocks—or any other clock, for that matter, including your biological clock—must exhibit the same time-dilation effects as a light clock. It is time itself that dilates!

Even though time dilation is extremely small at everyday speeds, it has been measured by comparing two atomic clocks (which are not light clocks), one at rest on the surface of Earth and the other aboard an aircraft (see the box "Desynchronized twins" on page 472).

Direct evidence that the time interval between two events depends on the motion of the observer is provided by cosmic-ray muons, fast-moving elementary particles created when highly energetic protons from deep space collide with atoms some 10 km up in Earth's atmosphere. Laboratory experiments show that muons at rest have a *half-life* of 1.5×10^{-6} s. That is, if you have 100 muons at some instant $t = 0$, half of them will decay into some other type of particle during one half-life. Thus you will have only 50 muons left at $t = 1.5\ \mu$s, 25 left at $t = 3.0\ \mu$s, and so on.

Traveling at a speed nearly equal to c_0, a muon travels 450 m in 1.5×10^{-6} s, and so the number of muons should decrease by a factor of 2 each 450 m they travel through the atmosphere. Experiments done at the top of Mt. Washington at an altitude of 1900 m showed that 568 muons strike a certain detector per hour. At sea level the muons have traveled an additional 1900 m, or about four times 450 m, and so the count should be diminished by a factor of $\left(\frac{1}{2}\right)^4$, yielding approximately 35 muons per hour. When the same detector is placed at sea level, however, not 35 but 412 muons per hour are detected—more than ten times as many as expected. How can this be?

Because of the time dilation that occurs at the speed they travel, the muons' half-life of 1.5×10^{-6} s is stretched to 1.4×10^{-5} s in our reference frame at rest on the ground. So, in the Earth reference frame the muons exist long enough for a substantial fraction of them to reach the ground before disintegrating.

14.8 Could you lengthen your life by traveling at high speed?

Motion is a relationship between time and distance. Thus, now that we understand how relative motion

CONCEPTS

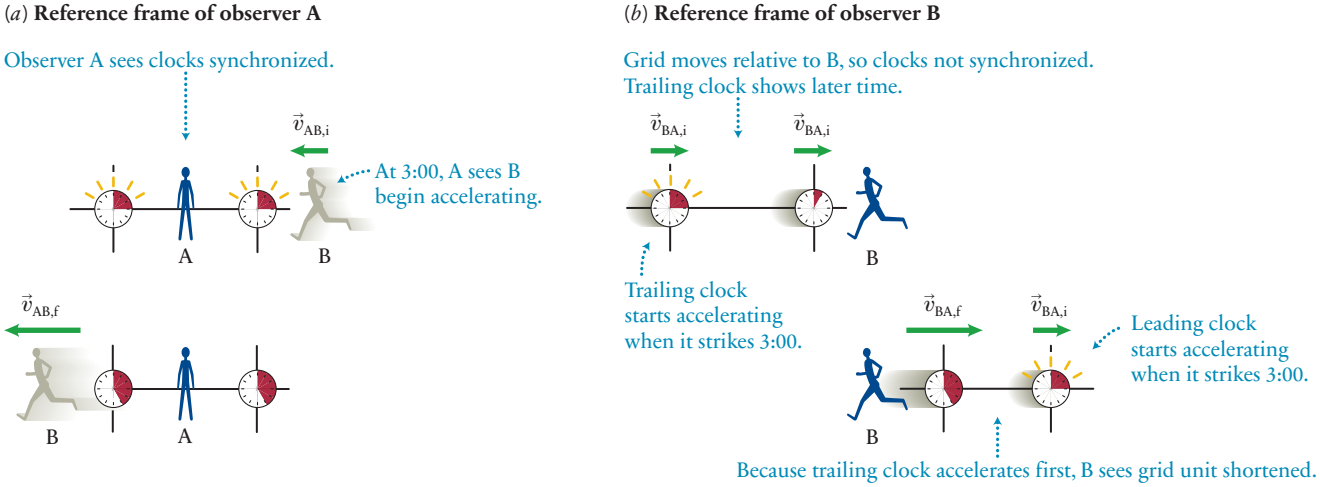
Desynchronized twins

Suppose one member of a set of twins embarks on a space trip, flying away from Earth at a speed of $0.98c_0$. Ten years after her departure, she turns around and returns to Earth, again traveling at speed $0.98c_0$. To observers on Earth monitoring the trip, clocks on the space ship run five times more slowly than clocks on Earth. Likewise, the twin's heart—a clock—beats five times more slowly. Consequently, by the time she returns to Earth, she has aged not 20 years but 4 years (20 years/5)! When she meets her twin brother again, who has remained Earthbound this whole time interval, he's 16 years older than she is. According to him, she's been gone 20 years, but to her, the trip lasted only 4 years.

This scenario is disturbing because it defies our commonsense notion of time. The experiment has been carried out with a pair of identical ("twin") atomic clocks, one flown Eastward twice around the world while the other sat at the airport. Upon its return, the flown clock was behind the airport clock, and the time difference matched what theory predicts.

This desynchronization of twins (or twin clocks) is sometimes called the *twin paradox* because viewing the situation from the perspective of the traveling twin appears to yield a contradiction: To her it is her brother on Earth who is moving at $0.98c_0$, and so *he* should be the one aging more slowly! The paradox is that, as explained earlier, she does not see him as being 16 years younger—both agree that she is the younger one once the trip is over. In other words, even though she sees Earth/brother moving at $0.98c_0$ and so should see Earth clocks running *slow,* these Earth clocks measure a *longer* duration for her trip than her own clocks. How can this be?

The key to resolving this paradox is to remember that the brother remains in an inertial reference frame during the entire trip, but the sister doesn't. The spaceship has to turn around to return to Earth, and this change in direction means acceleration. During this acceleration, a marble initially at rest on the floor of the spaceship does not remain at rest, and thus there is a time interval during the trip when she is in a noninertial reference frame. In contrast, a marble initially at rest on Earth's surface is not affected by the spaceship's acceleration: in other words, the Earth remains an inertial reference frame all the while the traveling twin is away. Thus the physical situation is different in the two reference frames: the Earth reference frame always inertial, the reference frame of the spaceship not always inertial. The theory of special relativity shows that during the time interval in which she is accelerating, the sister would see Earth clocks speed *up,* so that when she gets back to Earth, she is not at all surprised to see that her brother has aged much more than she has.



changes our ideas about time measurements, a logical next question to investigate might be whether motion changes the measurement of *distance*. In other words, is there a length change analogous to time dilation? An intriguing thought experiment shows us that the answer is yes. Picture yourself traveling along with some muons as they move from the summit of Mt. Washington to sea level. They are at rest relative to you, and so there is no time dilation in your reference frame: According to your clock, the muons have a (proper) half-life of 1.5×10^{-6} s. If you are traveling with the muons (at rest in their reference frame), you see the ground rushing toward you at a speed of nearly c_0. Thus it should still take 4 half-lives for the surface of the sea to travel the 1900 m toward you, and as a result you should again see about 35 muons by the time sea level reaches you. You see 412, though, just as before. Because you "know" that the muon half-life is 1.5×10^{-6} s, you are forced to conclude that the height of Mt. Washington has somehow shrunk!

Another way to see that length measurements are affected by motion is to imagine measuring the length of a *moving* car. One way would be to record the positions of the front and back of the car on the pavement and then measure the distance between those marks. You need to make sure that you record the two positions simultaneously, however, because the car is moving relative to you. If you record the back position at one instant and the front position some time later, you won't get a correct result. Remember, however, that simultaneity is a relative concept, and therefore we can expect length measurements also to depend on the motion of an observer relative to the object whose length the observer is measuring.

To see how length measurements are affected by motion, consider again a grid unit with a pair of clocks. The unit is at rest and the clocks are synchronized in the reference frame of observer A (**Figure 14.18*a***). Suppose a second observer B speeds up leftward when the clocks read 3 o'clock in A's reference frame. Because the clocks are synchronized, both of them read 3 o'clock in A's reference frame when observer B begins speeding up. From observer B's perspective, observer A and the clocks speed up to the right (Figure 14.18*b*). Because observer B is moving relative to the grid unit, the clocks are desynchronized, with the clock on the

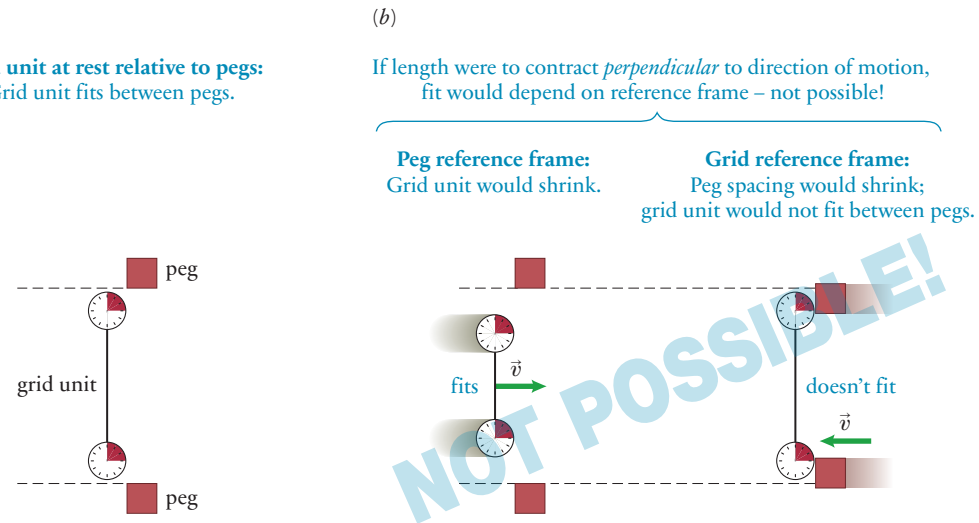
CONCEPTS

Figure 14.18 Length contraction of an accelerating grid.

trailing end being ahead of the clock on the leading end (see Figure 14.13). In observer B's reference frame, therefore, the clock on the trailing end strikes 3 o'clock and begins speeding up *before* the clock on the leading end does. Consequently B sees the distance between the clocks (and the length of the rod between them) decrease. Whenever the unit speeds up in B's reference frame, B sees the length of the rod decrease. The faster the unit moves, the shorter the rod appears to B.

When the unit slows down relative to observer B, the opposite happens: The clock on the trailing end begins slowing down *before* the clock on the leading end begins slowing down, and so B sees the rod become longer again. When the unit is at rest relative to B, she measures the rod to have its **proper length:**

> **The length of an object measured by an observer at rest relative to the object is called the object's proper length.**



An observer measuring the length of an object moving relative to the observer always measures a value that is shorter than the object's proper length.

> **14.9** Suppose observer B in Figure 14.18 carries a unit of two synchronized clocks that is identical to the unit that is at rest relative to A. Observer B begins speeding up when the clocks in her reference frame read 3 o'clock. What happens to the length of B's unit according to observer A?

As this checkpoint shows, the shortening of the rod's length, like time dilation, is symmetrical, in agreement with the principle of relativity. Each observer sees the other observer's grid move at the same relative speed and therefore shortened by the same amount.

Note that the shortening occurs only in the direction of motion. To see why, consider our clock grid unit aligned as in **Figure 14.19**. With the unit at rest, pegs are

Figure 14.19 Length contraction cannot occur in a direction perpendicular to the direction of motion.

CONCEPTS

Common sense and special relativity

That observers who are in motion relative to each other assign different values to the length of an object and to the time interval between two events clashes with common sense. Even though experiments confirm the predictions of special relativity, it is hard to believe that, say, the length of a rod and the time interval between your lunch and dinner do not have fixed, absolute values. This difficulty arises from the fact that in everyday circumstances we can get away with treating lengths and time intervals as invariants.

How "real" then is length contraction or the slowing down of clocks? It is just as real as the pitch of an approaching car horn sounding higher than that of a stationary or receding car. (This phenomenon is called the *Doppler effect;* see Section 17.7.) Riding along in a car with a stuck car horn, you measure the same pitch a roadside observer would measure when the car is at rest. Yet there is no denying that the pitch is perceived to change when car and observer are in motion relative to each other. These observations don't mean that the horn changes when it moves relative to an observer. What changes is the pitch *perceived by the observer*.

The same statements can be made about a moving rod. Any observer measuring the rod's length when the rod is at rest relative to him obtains the same value as you would (the proper length). Just as the pitch of a moving car horn is perceived to be changing, so is the measured length of a moving rod. The rod itself doesn't change—the *measurement of its length* yields a different value. In that sense relativistic effects are every bit as real as the changing pitch of a horn. For example, few muons would make it across what we measure to be 10 km of atmosphere if that length did not appear to be shortened to less than 1 km to them.

placed above and below it so that it fits snugly between them (Figure 14.19*a*). If the unit were to get shorter when it is in motion, it would fit more easily between the pegs (Figure 14.19*b*). Now imagine observing the same situation while traveling along with the unit. The unit is now at rest from your point of view and so does not shorten. The pegs, however, are in motion relative to you, and so the distance between them becomes smaller and the clocks hit the pegs. However, whether or not the clocks hit the pegs cannot depend on the reference frame of the observer, and so there cannot be any shortening in a direction perpendicular to the direction of motion.

When we discussed time dilation and considered the moving light clock in Figure 14.14*b*, we tacitly assumed its height to be fixed. Now we see that this assumption was justified.

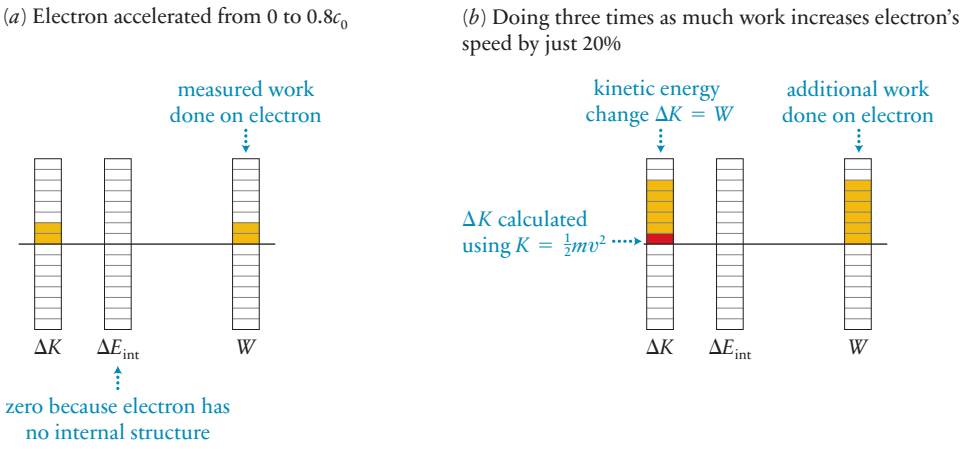
The shortening of objects in the direction of motion is called **length contraction:**

> **When an object moves relative to an observer, the observer measures the length of the object in the direction of its motion to be shorter than the proper length of the object.**

Length contraction is a direct consequence of the relativity of simultaneity. Returning to the cosmic-ray muons, we can now see why they reach Earth's surface. To them, Earth's atmosphere flies by at nearly the speed of light. Length contraction reduces the thickness of the atmosphere so much that the atmosphere passes by the muons before they decay. To us on the ground, time dilation lengthens the half-life of the muons, and so they can cross the proper length of the atmosphere. To them, length contraction decreases the distance to the ground, and so they reach the ground during their proper lifetime.

Time and space are connected. If we consider time and space to constitute a four-dimensional *space-time* entity, we see that, depending on the reference frame, the time dimension stretches (dilates) and one of the three spatial dimensions contracts. As we shall see in Section 14.5, a quantity called the *space-time interval* remains unaffected by this distortion of space-time geometry. At everyday speeds, these distortions are so small that they are not perceived. For motions at very high speeds, such as that of cosmic-ray muons, however, the consequences of these effects can be significant (see the box "Common sense and special relativity").

CONCEPTS



14.10 Consider a long pole moving through a tunnel, with the direction of motion being along the long axis of the pole. An observer on the ground determines that the moving pole has the same length as the tunnel. Does an observer moving along with the pole agree that the pole fits exactly in the tunnel?

14.4 Matter and energy

We developed the entire framework of mechanics from our everyday notions of space and time. In Chapters 2 and 3, we introduced the definitions of displacement, velocity, and acceleration. Then we introduced inertia, which depends on a ratio of changes in velocity (see Section 4.5). Many other quantities, such as momentum, energy, and force, in turn depend on inertia. So all the physics we have developed so far hinges on our concepts of space and time.

As we just saw in the preceding sections, however, everyday notions of space and time fail at very high

Figure 14.20 Simplified energy diagrams for accelerating an electron.

speed. Additionally, there is plenty of experimental evidence that our notion of energy fails at very high speeds. For example, experiments show that quadrupling the kinetic energy of an electron initially moving at $0.8c_0$ by doing work on it increases its speed by just 20% rather than doubling it as we would expect from the expression $K = \frac{1}{2}mv^2$.

Figure 14.20*a* shows the energy diagram for accelerating an electron from rest to $0.8c_0$. (The diagram is simplified by lumping all internal energy into one bar.) Because electrons have no known internal structure, $\Delta E_{int} = 0$, and so only their kinetic energy can change by doing work on them. The change in kinetic energy must thus be equal to the work done on the electron.

Now suppose we do additional work on the electron after it has attained a speed of $0.8c_0$. If the additional work is three times the amount of work done in accelerating the electron from rest to $0.8c_0$, our expression for kinetic energy, $K = \frac{1}{2}mv^2$, predicts a new speed that is twice the original speed: $v_f = 1.6c_0$. Experiments show, however, that the speed increases by just 20% and the value we obtain for ΔK using the expression $K = \frac{1}{2}mv^2$ is very much smaller than expected (Figure 14.20*b*). We must therefore conclude that our expression for kinetic energy is not valid at high speeds.

This experiment shows that it is more difficult to accelerate an electron when it is moving at $0.8c_0$ than when it is at rest. Now remember that an object's inertia is a measure of its resistance to acceleration (Section 4.2). We have so far assumed that an object's inertia is constant—an intrinsic property that is independent of the object's physical state or motion relative to an observer. Experimental data show that this assumption does not hold as an object's speed approaches c_0. In particular, as its kinetic energy increases, the object's inertia increases.

14.11 Do two observers, one moving at very high speed relative to the other, agree on the inertia of an object? Why or why not?

As Checkpoint 14.11 shows, inertia depends on the reference frame and therefore is not an invariant. In Chapter 13 we introduced mass—the property that determines the gravitational interaction of objects. The way in which objects interact gravitationally cannot depend on the motion of an observer relative to the interacting objects, which means that, in contrast to inertia, mass must be an invariant. That is to say, all observers should agree on the value of the mass of an object, regardless of their motion relative to the object. That mass is an invariant and inertia is not implies that there *is* a difference between mass and inertia, contrary to what we established in Chapter 13. As we shall see in Section 14.7, the difference between the two becomes apparent only at very high speeds.

Let us now turn to the nonkinetic part of energy: internal energy. Remember that the internal energy of an object or system is a quantitative measure of the state of that object or system. Because the state of an object cannot depend on the motion of the observer relative to the object, internal energy also must be an invariant.

So, we see that kinetic energy and inertia are not invariants, but internal energy and mass are. We also found that inertia depends on kinetic energy. Experiments show a similar connection between mass and internal energy. The primary example is provided by nuclear reactions, such as those taking place in the Sun. One of these reactions is the fusion of a proton and a deuteron D (the nucleus of a hydrogen isotope consisting of one neutron and one proton) to form a helium-3 nucleus (two protons and one neutron), while 8.80×10^{-13} J is released as radiation energy:

$$p + D \rightarrow {}^3He + \text{radiation}.$$

CONCEPTS

Figure 14.21 Simplified energy diagram for the fusion of a proton and a deuteron. During the reaction, nuclear energy is emitted in the form of radiation (identified as R). Experiments show that the amount of energy released is 8.80×10^{-13} J.

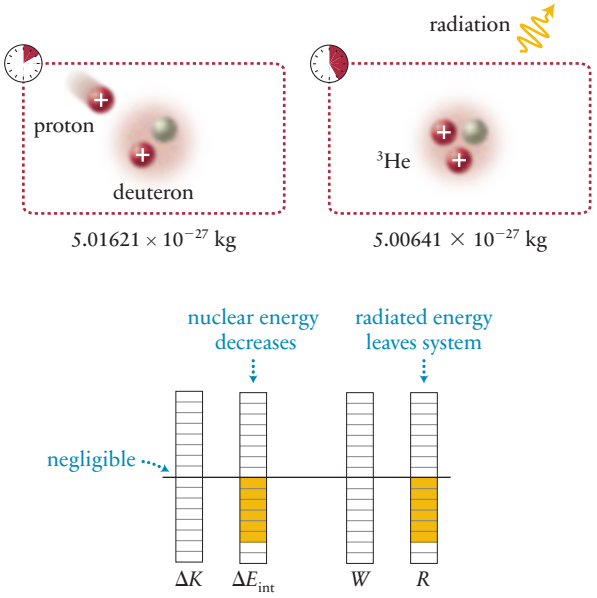


Figure 14.22 An ionized deuterium molecule and a helium ion contain the same elementary particles, yet have different masses. (Nuclei not to scale.)

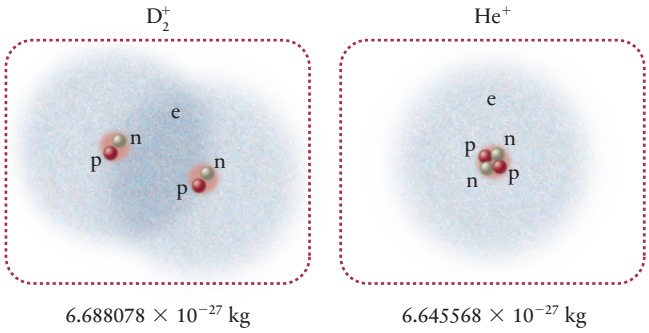

Figure 14.21 shows a simplified energy diagram for this reaction. Given that this is a nuclear reaction, nuclear energy (a form of internal energy) must be converted to radiation energy. Because the radiation energy leaves the system, the internal energy decreases.

Measurements show that the sum of the mass of the proton and the mass of the deuteron ($m_p + m_D = 5.01621 \times 10^{-27}$ kg) is greater than the mass of the helium-3 nucleus (5.00641×10^{-27} kg). In other words, the mass of the system decreases as its internal energy decreases.

Another example of the connection between mass and internal energy is provided by comparing the masses of an ionized deuterium molecule and an ionized helium atom (**Figure 14.22**). Both consist of two protons, two neutrons, and an electron, but the two particles have different configurations. Accurate measurements show that this different in configuration—which means a difference in internal energy—results in a small mass difference.

These observations indicate a relationship between mass and internal energy that is parallel to the one between inertia and kinetic energy:

Increasing the internal energy of a system increases the mass of the system.

Mass is a property we associate with particles or objects that have physical substance—made of what we call "matter." Internal energy is a quantitative measure of the object's state. Now we see that the two are proportional to each other and that whenever a system's state changes, both its internal energy and its mass change.

14.12 In each of the following situations, does the mass of the system increase, decrease, or stay the same? (*a*) A spring is compressed (system: spring). (*b*) A cup of coffee cools down (system: coffee).

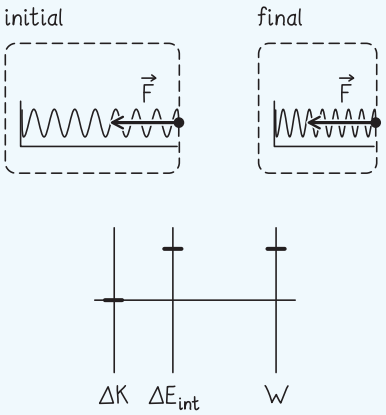
EXERCISE 14.5 The mass of energy

(*a*) In the nuclear reaction illustrated in Figure 14.21, what amount of mass is "lost"? (*b*) What is the ratio of energy decrease to mass loss as a result of the reaction? (*c*) Show that the units of your answer to part *b* are equivalent to m^2/s^2.

SOLUTION (*a*) The mass decreases by $(5.00641 \times 10^{-27}\ \text{kg}) - (5.01621 \times 10^{-27}\ \text{kg}) = -9.80 \times 10^{-30}$ kg. ✔

(*b*) The text states that the energy released in the reaction is 8.80×10^{-13} J. Therefore the ratio of energy decrease to mass loss is $(8.80 \times 10^{-13}\ \text{J})/(9.80 \times 10^{-30}\ \text{kg}) = 8.98 \times 10^{16}$ J/kg. ✔

(*c*) $\text{J/kg} = (\text{kg} \cdot \text{m}^2/\text{s}^2)/\text{kg} = \text{m}^2/\text{s}^2$. ✔



EXAMPLE 14.6 Spring mass

A spring of spring constant $k = 0.16$ N/m is compressed to half its 50-mm relaxed length. Using the result of Exercise 14.5, determine the change in the spring's mass.

❶ **GETTING STARTED** I begin by drawing a simplified energy diagram for the compressed spring (**Figure 14.23**). The work done on the spring during the compression increases the spring's potential energy and therefore the spring's internal energy. I need to determine the increase in mass corresponding to this energy increase.

CONCEPTS

Figure 14.23

2 DEVISE PLAN To calculate the increase in the spring's potential energy, I can use Eq. 9.23, $\Delta U_{\text{spring}} = \frac{1}{2}k(x - x_0)^2$. In part *b* of Exercise 14.5, I determined the ratio of energy change to mass change. I can use this ratio to convert the spring's energy change to a mass change.

3 EXECUTE PLAN The spring has been compressed by an amount $x - x_0 = 50\text{ mm} - 25\text{ mm} = 2.5 \times 10^{-2}\text{ m}$. From Eq. 9.23, I get $\Delta U_{\text{spring}} = \frac{1}{2}(0.16\text{ N/m})(2.5 \times 10^{-2}\text{ m})^2 = 5.0 \times 10^{-5}\text{ J}$. In Exercise 14.5*b*, I found that the ratio of energy change to mass change is $8.98 \times 10^{16}\text{ J/kg}$, so the change in the spring's mass is $(5.0 \times 10^{-5}\text{ J})/(8.98 \times 10^{16}\text{ J/kg}) = 5.6 \times 10^{-22}\text{ kg}$. ✔

4 EVALUATE RESULT The change in the spring's mass is much too small to be measured. That is reassuring because in my experience I've never been able to observe any change in mass when compressing springs.

Exercise 14.5 and Example 14.6 show that the ratio of mass change to energy change is very small; that is, a tiny amount of mass corresponds to an enormous amount of energy. Table 14.1 lists the fractional changes in mass for a number of changes in state (corresponding to changes in energy). As a rule of thumb, nuclear reactions release an amount of energy corresponding to about 10^{-3} of the mass; chemical reactions release an amount of energy corresponding to about 10^{-9} of the mass. As you can see from the table, other processes cause even smaller fractional changes in mass. For example, no one has been able to observe the change in mass that occurs when we heat a cup of tea because this change is on the order of 10^{-13} kg, much too small to measure.

In Chapter 13 we established that mass and inertia are equivalent at everyday speeds. Consequently increasing the internal energy of an object at rest must increase not only the object's mass but also its inertia. So, whereas mass depends on internal energy only, inertia depends on both internal energy and kinetic energy:

> **Increasing the energy $E = K + E_{\text{int}}$ of a system increases its inertia. The increase in inertia is the same whether the added energy goes into kinetic energy K, internal energy E_{int}, or a combination of the two.**

Table 14.2 summarizes the correspondence between matter and energy. The mass and internal energy of a system are invariants—that is, independent of the motion of observer and system relative to each other. Inertia and energy are not invariants. In addition, energy is a conserved quantity. In the second part of this chapter, we'll use the conservation principles to derive quantitative expressions for the relationships between mass and internal energy and between inertia and energy.

Table 14.1 Changes in energy and fractional mass changes due to changes in state

System before	System after	Energy change (J)	Fractional change in system's mass
1-kg book and Earth	1-kg book and Earth separated by an additional 1 m	10	2×10^{-41}
cup of tea	cup of tea heated by 10 °C	4000	5×10^{-13}
1 mole of H_2 molecules	2 moles of H atoms	5×10^{5}	3×10^{-9}
p + D	^{3}He	9×10^{-13}	2×10^{-3}

Table 14.2 Matter and energy

Quantity	Invariant?	Conserved?	Related to
E_{int}	yes	no	mass
E	no	yes	inertia

14.13 Do the inertia and mass of the system increase, decrease, or remain the same when (*a*) an elementary particle is accelerated (system: particle) and (*b*) an elementary particle slams into a metal target (system: particle and target)?

CONCEPTS

Self-quiz

1. Imagine you are at the origin of Figure 14.6, where, as in Exercise 14.2, a light pulse takes 1 s to travel one grid unit. When your clock reads 12:00:05, what do you observe as the reading on the clocks at positions (3, 0) and (0, 2)?
2. Which of the following statements are true when we compare a moving light clock and one at rest in the Earth reference frame? (*i*) The signal in the moving clock travels a greater distance during one cycle. (*ii*) The signal in the moving clock takes more time to complete one cycle. (*iii*) The cycle on the moving clock is longer. (*iv*) Time on the moving clock runs more slowly. (*v*) The moving clock completes an hour first.
3. Standing near the finish line at a race track, you measure the time interval between two cars as they cross the finish line. Is the time interval between these events as measured by the driver in the second car the same as, greater than, or less than the time interval you measure?
4. A particle of mass m is moving at speed v toward an identical particle that is at rest in the Earth reference frame. Is the inertia of the particles in their zero-momentum reference frame greater than, equal to, or less than m?
5. An observer on the ground observes a car moving past a gate and notes that the car is longer than the gate. For an observer in the car, which of the following are possibilities? (*i*) The gate is longer than the car. (*ii*) The gate is the same length as the car. (*iii*) The gate is shorter than the car.

Answers

1. Because it takes 1 s for light to travel one grid unit, it takes 3 s for the clock at (3, 0) to be seen by you. Its time is thus 3 s earlier than that of the origin clock, or 12:00:02. The light from the clock at (0, 2) takes 2 s to reach you, and so that clock reads 12:00:03.
2. All but (*v*) are true. Because the signal in the moving clock travels an equal vertical distance but a greater horizontal distance, the overall distance is greater. At constant speed, a greater distance requires a longer time interval. This longer time interval makes the duration of the clock's cycle longer, and the clock runs slow. If the clock runs slow, the hour passes less quickly.
3. Because you measure both events at the same position, you obtain the proper time interval between them. The driver in the second car moves relative to you, and so, according to the argument used in the solution to Example 14.4, measures a longer time interval.
4. In the zero-momentum reference frame both particles are moving, and therefore each particle has an inertia that is greater than the mass m.
5. Because moving objects contract in the direction of motion, the gate gets shorter to the observer in the car. Because the gate is shorter than the car in the Earth reference frame, it is also shorter in the car's reference frame. Thus only (*iii*) is possible.

14.5 Time dilation

Let us determine how the period of a light clock depends on the motion of the clock relative to the observer. The time interval between the instant a light signal is emitted at the bottom of a light clock and the instant the signal returns to the bottom is the period of that clock. In the reference frame of observer A in **Figure 14.24*a***, the clock of height h is at rest, and so the period measured by observer A is $T_A = 2h/c_0$. In the reference frame of observer B, the clock is in motion and the signal follows the inverted-V path shown in Figure 14.24*b*. Because this path is longer than $2h$, the period T_B measured by observer B is longer than T_A.

During one round trip of its light signal, the clock moves a distance vT_B to the right in B's reference frame. From the right triangle in Figure 14.24*b*, we see that the distance d traveled by the signal during that time interval must satisfy

$$\left(\frac{d}{2}\right)^2 = h^2 + \left(v\frac{T_B}{2}\right)^2. \tag{14.1}$$

Because the signal travels at speed c_0, we have $d = c_0T_B$. Substituting this relationship into Eq. 14.1 and multiplying the result by 4 to remove any fractions, we get

$$(c_0T_B)^2 = 4h^2 + (vT_B)^2 \tag{14.2}$$

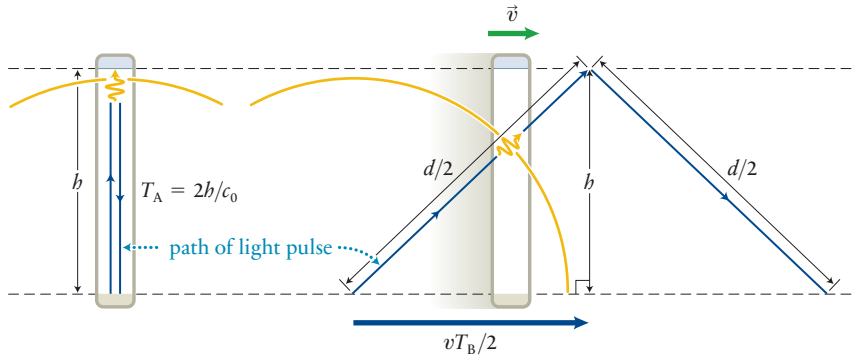
or

$$(c_0^2 - v^2)T_B^2 = 4h^2. \tag{14.3}$$

Dividing both sides of this equation by c_0^2 gives

$$\frac{c_0^2 - v^2}{c_0^2}T_B^2 = \frac{4h^2}{c_0^2} = T_A^2, \tag{14.4}$$

where we have used $T_A = 2h/c_0$. Rearranging terms, we get



$$T_B = \sqrt{\frac{c_0^2}{c_0^2 - v^2}}T_A = \frac{1}{\sqrt{1 - v^2/c_0^2}}T_A. \tag{14.5}$$

Because the factor in front of T_A is greater than 1 for $0 < v < c_0$, we see that $T_B > T_A$, as expected.

Figure 14.24 The period of a light clock moving relative to an observer is determined by the time interval it takes the light signal to travel the two diagonal distances $d/2$.

(*a*) **Reference frame of observer A:** clock at rest relative to observer

(*b*) **Reference frame of observer B:** clock moving relative to observer

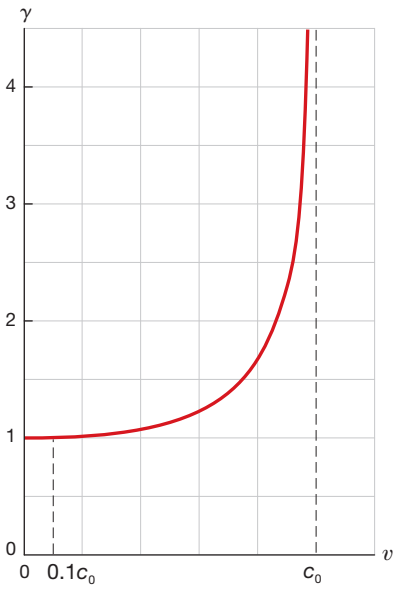


Figure 14.25 As the speed v at which any object travels approaches c_0, the Lorentz factor γ approaches infinity. Up to a speed of about $0.1c_0$, γ is very close to 1.

Table 14.3 Gamma factor

v/c_0	γ
0	1
0.1	1.005
0.5	1.15
0.9	2.3
0.98	5.0
0.99	7.1
0.999	22
0.9999	71
0.99999	220
0.999999	710

The factor on the right side of Eq. 14.5 is often represented by the Greek letter gamma, γ, and called the **Lorentz factor:**

$$\gamma \equiv \frac{1}{\sqrt{1 - v^2/c_0^2}}. \tag{14.6}$$

This factor is a measure of how pronounced relativistic deviations are from our everyday notions of time and space. At ordinary speeds, $v \ll c_0$, and so $\gamma \approx 1$; at high speeds, γ approaches infinity, as shown in **Figure 14.25**.

Table 14.3 lists values of γ for some values of v/c_0. Note that γ remains very close to 1 even up to very high speeds. For example, an object traveling at $0.1c_0$ could circle Earth in about 1 s, and yet the deviation of γ from 1 is less than 1%, meaning that the effects of time dilation are very small. As a rule of thumb, we can say that for speeds less than $0.1c_0$ the deviation of γ from 1 is negligible. We'll refer to speeds less than $0.1c_0$ as *nonrelativistic speeds* and speeds greater than $0.1c_0$ as *relativistic speeds*.

Conversely, we can obtain the ratio v^2/c_0^2 from γ by first squaring Eq. 14.6:

$$\gamma^2 = \frac{1}{1 - v^2/c_0^2} \tag{14.7}$$

and then inverting this equation:

$$\frac{1}{\gamma^2} = 1 - \frac{v^2}{c_0^2}, \tag{14.8}$$

so

$$\frac{v^2}{c_0^2} = 1 - \frac{1}{\gamma^2}. \tag{14.9}$$

For nonrelativistic speeds, we can approximate γ as*

$$\gamma = \frac{1}{\sqrt{1 - v^2/c_0^2}} \approx 1 + \tfrac{1}{2}\frac{v^2}{c_0^2} \quad (v/c_0 \ll 1), \tag{14.10}$$

so

$$\gamma - 1 \approx \tfrac{1}{2}\frac{v^2}{c_0^2} \quad \text{(within two significant digits when } v < 0.1c_0\text{)}. \tag{14.11}$$

As you will see shortly, this equation is useful for calculating γ when $v < 0.1c_0$.

14.14 Taking each motion to be relative to the Earth reference frame, calculate γ for (*a*) a car moving at 30 m/s, (*b*) an airplane moving at 250 m/s, (*c*) a spacecraft moving at 10,000 m/s, and (*d*) an electron moving at $0.60c_0$.

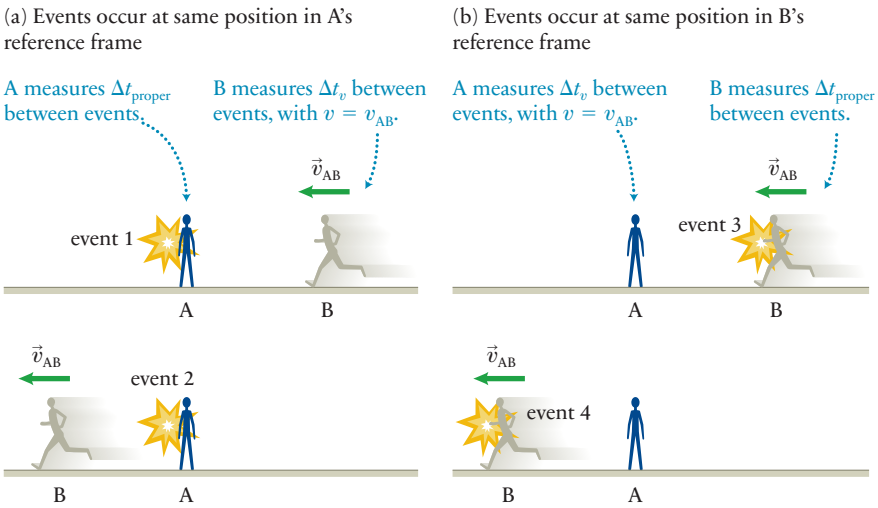
Using the factor γ, we can simplify Eq. 14.5 to

$$T_B = \gamma T_A. \tag{14.12}$$

*From the binomial expansion $[\sqrt{1+\epsilon}\,]^{-1} = 1 - \frac{1}{2}\epsilon + \frac{3}{8}\epsilon^2 + \cdots$ (see Appendix B). For small ϵ, we can ignore terms of order ϵ^2 and higher.

QUANTITATIVE TOOLS

This equation provides an exact quantitative expression for time dilation. In words, the period T_B measured by an observer in motion relative to the clock is lengthened by a factor γ relative to the period T_A measured by an observer at rest relative to the clock. Note that T_B is not a proper time interval between the emission of successive light signals because these events occur at different positions in the reference frame of the observer. Only an observer at rest relative to the clock can measure the proper time interval between the emission of successive light signals. To this observer, the clock is at rest, and so the light signal travels a distance $2h$ between successive emission events. The proper time interval between the emission of successive signals in the clock is thus $2h/c_0$.



Time dilation does not occur in light clocks only. As we pointed out in Section 14.3, the principle of relativity tells us that any clock should exhibit the same effects. Time dilation affects the measurement of the time interval between any two events and therefore time itself. Generalizing Eq. 14.12, we can say that the time intervals between two events as measured by two observers in motion relative to each other are related by

$$\Delta t_v = \gamma \Delta t_{\text{proper}}, \tag{14.13}$$

where Δt_{proper} is the time interval measured by an observer for whom both events occur at the same position, Δt_v is the time interval between the same two events measured by a second observer moving at speed v relative to the first observer, and γ is the factor given by Eq. 14.6.

Note that Eq. 14.13 involves two observers measuring the time interval Δt between two events. When applying this equation, you must therefore always begin by identifying the two events and the two observers. Next you should determine which observer measures the proper time interval and what speed v to use in Eq. 14.13. As an example, consider **Figure 14.26**. In Figure 14.26*a* two events occur at the same position relative to observer A, and so A measures the proper time interval Δt_{proper}. Observer B moves at speed v_{AB} relative to A, and so she measures a time interval $\Delta t_v = \gamma \Delta t_{\text{proper}}$, where the v in γ is equal to v_{AB}. In Figure 14.26*b* two events occur at the same position relative to B, and so B measures the proper time interval Δt_{proper}. Observer A moves at speed $v_{BA} = v_{AB}$ relative to B and so he measures a time interval $\Delta t_v = \gamma \Delta t_{\text{proper}}$, where the v in γ is equal to v_{AB}.

Figure 14.26 Proper time measurements.

EXAMPLE 14.7 Flight delay

You are on an airplane flying at a steady 250 m/s at cruising altitude. At noon the pilot announces that you are passing over the center of London and exactly 6.0 h later, according to your watch, comes on the address system to say that you are passing over Abu-Dhabi. (*a*) Do observers on the ground measure a longer, equal, or shorter time interval between these two events? (*b*) Is the difference between the time interval measured on the ground and that measured by your watch detectable?

❶ **GETTING STARTED** This problem involves two reference frames (the Earth reference frame and the reference frame of the plane) and two events (plane passing over London and plane passing over Abu-Dhabi). I denote the plane passing over London as event 1 and the plane passing over Abu-Dhabi as event 2. The time interval between these events is 6.0 h in the reference frame of the plane.

❷ **DEVISE PLAN** The proper time interval is the shortest time interval between the events, and so this problem boils down to determining who measures the proper time interval. Once I have determined that, I can use Eq. 14.13 to determine the time interval measured by the ground observers and determine the difference between the two intervals.

❸ **EXECUTE PLAN** (*a*) Relative to the plane, events 1 and 2 occur at the same position. Therefore the 6.0-h time interval I measure is the proper time interval in the plane reference frame. The ground observers move at 250 m/s relative to my reference frame, and so, according to Eq. 14.13, they measure a longer time interval. ✔

(*b*) To determine the difference, I subtract the proper time interval from both sides of Eq. 14.13:

$$\Delta t_v - \Delta t_{\text{proper}} = \gamma \Delta t_{\text{proper}} - \Delta t_{\text{proper}} = (\gamma - 1)\Delta t_{\text{proper}}.$$

From Eq. 14.11 I have

$$\gamma - 1 \approx \tfrac{1}{2}\frac{v^2}{c_0^2} = \frac{(250\ \text{m/s})^2}{2(3.00 \times 10^8\ \text{m/s})^2} = 3.47 \times 10^{-13}.$$

The difference in the time intervals is thus $(3.47 \times 10^{-13})(6.0\ \text{h})(3600\ \text{s}/1\ \text{h}) = 7.5 \times 10^{-9}$ s, which is orders of magnitude smaller than can be detected with ordinary clocks. ✔

❹ **EVALUATE RESULT** That the difference in time intervals is too small to be easily measured is reassuring in two ways. First, from experience I know that my watch doesn't stop telling the correct time while flying (other than time zone adjustments). Second, the speed of the airplane is just a small fraction of the speed of light $(250\ \text{m/s})/(3.00 \times 10^8\ \text{m/s}) \approx 10^{-6}$, and so, for all practical purposes, $\gamma = 1$.

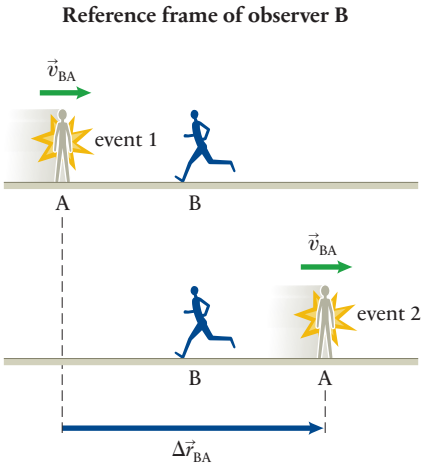


Figure 14.27 Observer B can determine the proper time interval between any pair of events by measuring the time interval between them and the distance separating them.

Let's examine Figure 14.26*a* from observer B's point of view and see if there is any way that B can determine the proper time interval between the two events without the need to refer to observer A's reference frame. In B's reference frame, the events occur at two locations (**Figure 14.27**). Let's choose the x axis such that we can denote A's displacement in B's reference frame by Δx. Relative to B, A moves at velocity $\vec{v}_{BA}$. If B measures a time interval Δt between the two events, then the x component of A's displacement is

$$\Delta x = v_{BAx}\Delta t = v_{BAx}\gamma \Delta t_{\text{proper}}, \tag{14.14}$$

where we have used Eq. 14.13 to convert Δt to the proper time interval between the events. Equation 14.14 relates the proper time interval to measurements taken entirely in B's reference frame (Δx and Δt), but the equation also contains the velocity of A's reference frame relative to B. To obtain an expression that does not contain this velocity requires a bit of algebraic manipulation on the expression $(c_0\Delta t_{\text{proper}})^2$. We begin by multiplying and dividing this quantity by γ^2, substituting Eq. 14.8 for $1/\gamma^2$:

$$(c_0\Delta t_{\text{proper}})^2 = \gamma^2(c_0\Delta t_{\text{proper}})^2\left(1 - \frac{v^2}{c_0^2}\right). \tag{14.15}$$

Multiplying out the term in parentheses, we get

$$(c_0\Delta t_{\text{proper}})^2 = c_0^2\gamma^2(\Delta t_{\text{proper}})^2 - v^2\gamma^2(\Delta t_{\text{proper}})^2. \tag{14.16}$$

Because $\Delta t = \gamma \Delta t_{\text{proper}}$ (Eq. 14.13), the first term on the right is equal to $(c_0\Delta t)^2$. The magnitude of velocity $\vec{v}_{BA}$ is equal to the speed v that appears in the Lorentz factor, and so we can write $v_{BAx}^2 = v^2$. Equation 14.14

then tells us that the second term on the right in Eq. 14.16 is equal to $(\Delta x)^2$, and so we can rewrite this equation as

$$(c_0\Delta t_{\text{proper}})^2 = (c_0\Delta t)^2 - (\Delta x)^2. \tag{14.17}$$

Note that the right side of this expression contains only measurements made in B's reference frame: the time interval Δt and the spatial separation Δx of the events. The quantity $c_0\Delta t$ represents the distance traveled by a light signal in the time interval between the events. The quantity

$$s^2 \equiv (c_0\Delta t)^2 - (\Delta x)^2 \tag{14.18}$$

is called the **space-time interval** between two events. Because both terms on the right in Eq. 14.18 have units m^2, we see that s^2 represents a distance squared.

Depending on how $c_0\Delta t$ compares to Δx, we can distinguish between different types of event pairs. When the distance $c_0\Delta t$ traveled by a light signal in the time interval between the events is greater than the distance between the events, $(c_0\Delta t)^2 > (\Delta x)^2$, and Eq. 14.18 tells us that $s^2 > 0$. For such a pair of events, there is an inertial reference frame for which the two events occur at the same position ($\Delta x = 0$) and the events are separated in time only. For this reason the space-time interval of a pair of events for which $s^2 > 0$ is said to be *timelike*. A clock in the reference frame in which the two events occur at the same position measures the proper time interval Δt_{proper} between the events and uniquely determines their sequence in time. Because the speed of light c_0 and the proper time interval Δt_{proper} between two events have definite values, any observer who measures the distance and time interval between the two events must obtain the same space-time interval $s^2 = (c_0\Delta t_{\text{proper}})^2$ between them. In other words, the space-time interval is an invariant, even though neither Δx nor Δt is an invariant.

In a reference frame where the two events do not occur at the same position, $\Delta x > 0$. When $s^2 > 0$, Eq. 14.17 tells us that, for any reference frame in which $\Delta x > 0$, the time interval Δt between the events is greater than Δt_{proper}, as we concluded earlier. When Δt_{proper} is positive, Δt must be positive in all reference frames, and so a sequence of events that has a timelike space-time interval is the same in all inertial reference frames.

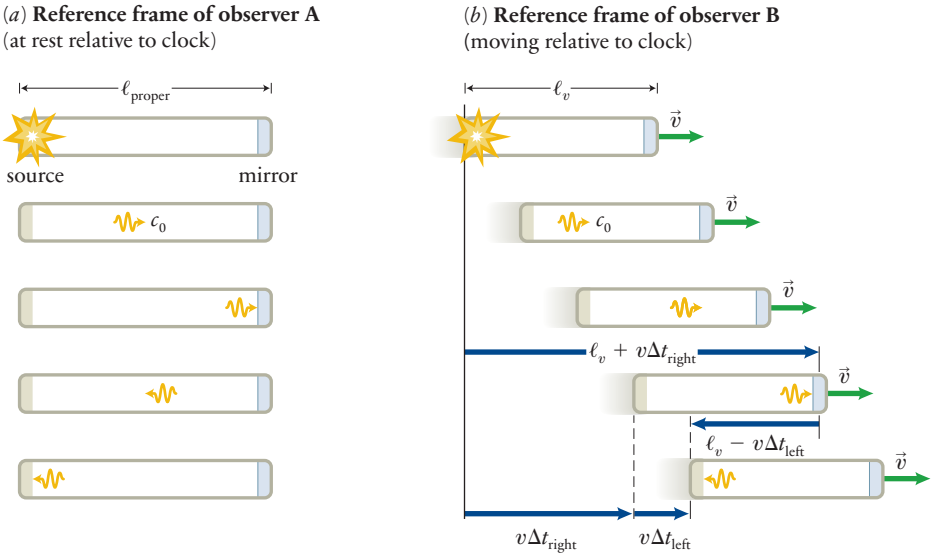
When the distance $c_0\Delta t$ traveled by a light signal in the time interval between the events is less than the distance Δx between them, Eq. 14.18 tells us that $s^2 < 0$. For such a pair of events, there is no inertial reference frame for which the two events occur at the same position and therefore the events have no proper time interval. There is, however, a reference frame for which the events are simultaneous ($\Delta t = 0$) and separated in space only: $(\Delta x)^2 = -s^2$. The space-time interval for a pair of events for which $s^2 < 0$ is therefore said to be *spacelike*. In any other reference frame, the events are not simultaneous, and we cannot uniquely determine their sequence. Depending on the reference frame, Δt can be positive, zero, or negative, and so either event may precede the other.

When two events are exactly separated by the distance that light travels in the time interval between them, $s^2 = 0$ and the space-time interval is said to be *lightlike*. When you look at a source of light (your desk lamp or a star, say), the emission of the light and your observation of that light are separated by a lightlike space-time interval.

Because the space-time interval s^2 is an invariant, it is timelike, spacelike, or lightlike regardless of the reference frame. How does the nature of the space-time interval affect the principle of causality we discussed in Chapter 1? To distinguish cause and effect, it is necessary to determine the

sequence of events. For a pair of events that have a timelike space-time interval ($s^2 > 0$), there is a reference frame in which we can study both events at the same position, and so we can determine their sequence with certainty and establish their causal relationship. For a pair of events that has a spacelike space-time interval ($s^2 < 0$), we cannot ascertain the time order of events and therefore cannot determine any causal relationship. For two events to be causally related, they must be able to interact physically. When $s^2 < 0$, the events occur in such rapid succession that a light signal cannot travel from one event to the other in the time interval between them. Because no information can travel faster than the speed of light, such events cannot interact and so cannot be causally related. Only events that have a timelike space-time interval can be causally related, and for such events the time sequence can be uniquely determined.

14.15 An elementary particle is observed to disintegrate after traveling 120 m in 5.0×10^{-7} s from the location where it was created. How long does the particle exist before disintegrating according to an observer at rest relative to the particle?



14.6 Length contraction

In Section 14.3 we saw that the length of an object measured by an observer moving relative to the object is shortened. Remember also that time dilation and length contraction are two manifestations of the same effect. To work out the amount of shortening, we now turn the clocks from Figure 14.24 on their side as in **Figure 14.28**, which shows the clock from the perspective of an observer A at rest relative to the clock and from the perspective of an observer B in motion relative to the clock.

We denote the proper length of the clocks by ℓ_{proper}. Our goal is to see what shortened length ℓ_v observer B obtains. According to A, the period of the clock is

$$T_{\text{A}} = \frac{2\ell_{\text{proper}}}{c_0}. \tag{14.19}$$

Figure 14.28 By calculating the distance traveled by the light pulse in the reference frame of the observer moving relative to the clock, we can work out by how much the length of the clock is shortened.

The period of the clock measured by B is given by Eq. 14.12: $T_B = \gamma T_A$. This period is the sum of two time intervals: the time interval Δt_{right} during which the light signal travels to the right from source to mirror and the time interval Δt_{left} during which the signal travels from mirror to source. During Δt_{right}, the clock moves a distance $v\Delta t_{right}$ as measured by B. The distance traveled by the signal during that time interval is thus $d_{right} = \ell_v + v\Delta t_{right}$. Because the signal travels at speed c_0 independent of the motion of the source or the motion of the observer, the distance traveled by the signal in the time interval Δt_{right} must be $d_{right} = c_0\Delta t_{right}$. Equating the two expressions for d_{right}, we have

$$c_0\Delta t_{right} = \ell_v + v\Delta t_{right}. \tag{14.20}$$

Solving for Δt_{right} yields

$$\Delta t_{right} = \frac{\ell_v}{c_0 - v}. \tag{14.21}$$

While the signal in the clock returns from the mirror to the source, the clock moves an additional distance $v\Delta t_{left}$.* The signal therefore travels a distance $d_{left} = \ell_v - v\Delta t_{left}$ again as measured by observer B. Because the signal travels at speed c_0 independent of the motion of the source or observer, the distance traveled by the signal in the time interval Δt_{left} must be $d_{left} = c_0\Delta t_{left}$. Equating the two expressions for d_{left}, we have

$$c_0\Delta t_{left} = \ell_v - v\Delta t_{left}. \tag{14.22}$$

Solving for Δt_{left} yields

$$\Delta t_{left} = \frac{\ell_v}{c_0 + v}. \tag{14.23}$$

Combining this result with Eq. 14.21, we get for the sum of the two time intervals

$$\begin{aligned} T_B &= \Delta t_{right} + \Delta t_{left} \\ &= \ell_v\left(\frac{1}{c_0 - v} + \frac{1}{c_0 + v}\right). \end{aligned} \tag{14.24}$$

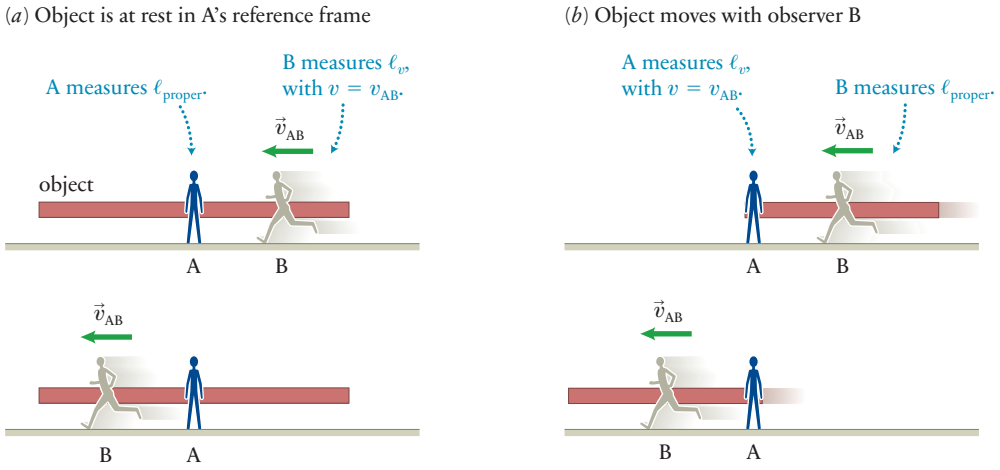
Combining terms, we obtain

$$T_B = \frac{2\ell_v c_0}{c_0^2 - v^2}. \tag{14.25}$$

Dividing the numerator and denominator on the right by c_0^2, we get

$$T_B = \frac{2\ell_v}{c_0}\left(\frac{1}{1 - v^2/c_0^2}\right) = \frac{2\ell_v}{c_0}\gamma^2, \tag{14.26}$$

where we have substituted γ^2 from Eq. 14.7. Substituting this expression for T_B and Eq. 14.19 for T_A into Eq. 14.12, we get



$$\frac{2\ell_v}{c_0}\gamma^2 = \gamma\frac{2\ell_{proper}}{c_0} \tag{14.27}$$

or

$$\ell_v = \frac{\ell_{proper}}{\gamma}. \tag{14.28}$$

*The subscript *left* refers to the motion of the light, not the motion of the clock.

Figure 14.29 Length measurements.

Because $\gamma > 1$, the measured length ℓ_v of the clock moving relative to us (or any other object moving relative to us) is shorter than its proper length ℓ_{proper}.

Note that Eq. 14.28 involves two observers measuring the length of an object: observer A at rest relative to the object and observer B in motion relative to it. When applying this equation, you must therefore always begin by identifying (1) the observers and (2) the observer's reference frame, if any, in which the object is at rest. The observer in this reference frame measures the object's proper length. As an example, consider the two observers in **Figure 14.29**. In Figure 14.29*a* the object is at rest in A's reference frame, and so A measures the proper length ℓ_{proper}. Observer B moves at speed v_{AB} relative to A, and so he measures a length $\ell_v = \ell_{proper}/\gamma$, where the v in γ is equal to v_{AB}. In Figure 14.29*b* the object is at rest relative to B, and so B measures the proper length ℓ_{proper}. Observer A moves at speed $v_{BA} = v_{AB}$ relative to B, and so she measures a length $\ell_v = \ell_{proper}/\gamma$, where the v in γ is equal to v_{AB}.

The Procedure box "Time and length measurements at very high speeds" summarizes how to treat time intervals and distances when dealing with motion at very high speeds.

PROCEDURE: Time and length measurements at very high speeds

At very high speeds, measurements of lengths and time intervals depend on the reference frame. Problems involving objects or observers moving at very high speeds therefore require extra care when we consider lengths and time intervals.

1. Identify each observer or reference frame with a letter and determine in which reference frame each numerical quantity given in the problem statement is measured.
2. If the problem involves any time intervals, identify the events that define that time interval. Determine in which observer's reference frame, if any, the two events occur at the same position. This observer measures the proper time interval between the events (Figure 14.26).
3. Identify any distances or lengths mentioned in the problem. Determine for which observer, if any, the object defining that distance or length remains at rest. This observer measures the proper length (Figure 14.29).
4. Use Eqs. 14.13 and 14.28 to determine the time intervals and lengths in reference frames other than the ones in which the intervals and lengths are given.

QUANTITATIVE TOOLS

EXAMPLE 14.8 Electron dash

An electron moving at $0.80c_0$ relative to the Earth reference frame travels the 100-m length of a building. What is the length of the building according to an observer moving along with the electron?

❶ **GETTING STARTED** This problem involves two reference frames: the reference frame of the building (which is the Earth reference frame) and the reference frame of the electron. Although the problem doesn't mention this explicitly, the 100-m length of the building is likely to be the length measured in Earth's reference frame, and so it is the building's proper length. I summarize this information in a table:

	Electron reference frame	Earth reference frame
v_{electron}	0	$0.8c_0$
ℓ_{building}	?	100 m

❷ **DEVISE PLAN** Equation 14.28 relates the building length measured by the observer in the electron's reference frame to the proper length. I know the building's proper length (100 m) and the speed of the observer relative to the reference frame in which the proper length is measured ($0.80c_0$). I can calculate γ from Eq. 14.6 and then use Eq. 14.28 to obtain the length of the building in the electron's reference frame.

❸ **EXECUTE PLAN** $\gamma = 1/\sqrt{1 - v^2/c_0^2} = 1/\sqrt{1 - (0.80)^2} = 1.67$, and so $\ell_v = \ell_{\text{building}} = (100\text{ m})/1.67 = 60\text{ m}$. ✔

❹ **EVALUATE RESULT** From our length contraction discussion in Section 14.3, I know that an observer measuring the length of an object that is moving relative to her measures a length shorter than the proper length. In this example, the observer is in the electron's reference frame, and the building being measured is moving relative to that reference frame. Therefore I expect the measured length to be shorter than the proper length.

EXAMPLE 14.9 Cosmic ray longevity

A proton strikes an air molecule in Earth's atmosphere, creating a muon 6.0 km above the ground. The muon travels toward Earth at nearly c_0 and decays just before reaching the ground. An observer traveling along with the muon determines that it lives for 2.2×10^{-6} s. According to this observer, what is the distance between the ground and the muon at the instant the muon is created?

❶ **GETTING STARTED** The problem mentions two reference frames: the Earth reference frame and the reference frame of the muon. The altitude is measured in the Earth reference frame, whereas the muon's lifetime is measured in the reference frame of the muon. The muon's lifetime is the time interval between its creation at an altitude of 6.0 km (event 1) and its decay at the ground (event 2). The speed of the muon in the Earth reference frame is (nearly) c_0. I summarize this information in tabular form:

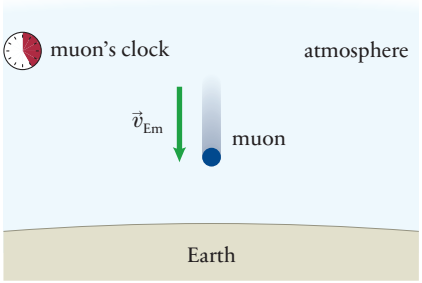
	Earth reference frame	Muon reference frame
Δt		2.2×10^{-6} s (proper time interval)
h_{atm}	6.0 km (proper length)	?
v_{muon}	c_0	

❷ **DEVISE PLAN** The 6.0-km distance traveled by the muon in the Earth reference frame is the proper length of the atmosphere. To calculate the (contracted) distance traveled by the muon in the muon reference frame, I can use Eq. 14.28, but I first need to determine γ for the motion of the muon. I can determine the time interval between events 1 and 2 in the Earth reference frame by dividing the distance traveled in the Earth reference frame (6.0 km) by the muon speed, which I take to be c_0. This time interval is the lifetime of the muon in the Earth reference frame. Because I know the muon lifetime in the reference frame of the muon (2.2×10^{-6} s), which is the proper time interval, I can use Eq. 14.13 to determine γ.

❸ **EXECUTE PLAN** The distance traveled in the Earth reference frame is 6.0×10^3 m, and so in this reference frame the time interval between events 1 and 2 is $\Delta t_v = (6.0 \times 10^3\text{ m})/(3.00 \times 10^8\text{ m/s}) = 2.0 \times 10^{-5}$ s. In the muon reference frame, the muon is at rest and exists for the proper time interval $\Delta t_{\text{proper}} = 2.2 \times 10^{-6}$ s. I can obtain γ from Eq. 14.13:

$$\gamma = \frac{\Delta t_v}{\Delta t_{\text{proper}}} = \frac{2.0 \times 10^{-5}\text{ s}}{2.2 \times 10^{-6}\text{ s}} = 9.1.$$

Using this value for γ, I determine the distance ℓ_v traveled by the muon in its reference frame from Eq. 14.28:



$$\ell_v = \frac{\ell_{\text{proper}}}{\gamma} = \frac{6.0 \times 10^3\text{ m}}{9.1} = 6.6 \times 10^2\text{ m}. \checkmark$$

❹ **EVALUATE RESULT** The muon lifetime in the Earth reference frame is longer than the muon's proper lifetime, as it should be. Because the muon lives longer in the Earth reference frame, it can travel a greater distance (6.0 km instead of 660 m). I can also check my result by considering the situation from the muon's reference frame. In that reference frame, the atmosphere flies by at nearly the speed of light for a time interval corresponding to the muon's proper lifetime, and so $\ell_v = c_0 \Delta t_{\text{proper}} = (3.00 \times 10^8\text{ m/s})(2.2 \times 10^{-6}\text{ s}) = 6.6 \times 10^2$ m, which is the result I got.

Figure 14.30 A muon created at the top of the atmosphere is able to reach the ground before decaying—but observers in the Earth reference frame and the muon reference frame would explain this result differently.

(*a*) **Earth reference frame**

Muon reaches ground because its clock runs slow.

(*b*) **Muon reference frame**

Muon reaches ground because atmosphere moves relative to it and hence is contracted.

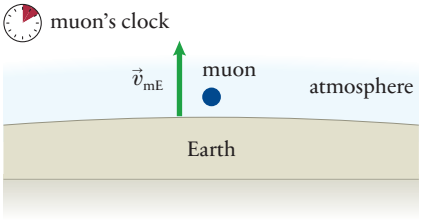


Table 14.4 Muon math

Reference frame	ℓ (km)	Δt (s)
Earth	6.0	2.0×10^{-5}
muon	0.66	2.2×10^{-6}

Figure 14.30 is a graphical representation of Example 14.9. To the observer in the Earth reference frame, the length of the muon's path is equal to the thickness (proper length) of the atmosphere, but the particle's lifetime is lengthened by time dilation (Figure 14.30*a*). Figure 14.30*b* shows the same decay viewed by the observer attached to the muon. To this observer, the muon is at rest and decays in the proper time interval, but the moving atmosphere is contracted. What appears as time dilation of the muon's lifetime to one observer appears as length contraction of the atmosphere to the other (**Table 14.4**). Time dilation and length contraction are thus two manifestations of the same effect.

In Chapter 6 we derived the Galilean transformation equations (Eqs. 6.4 and 6.5) to relate the coordinates of an event e in any two inertial reference frames A and B moving at constant velocity relative to each other. At very high speeds, these equations have to be replaced with equations that take into account the effects of time dilation and length contraction. For two reference frames A and B that have origins that coincide at $t_A = t_B = 0$ and that are moving at constant velocity in the x direction relative to each other, the new equations, called the **Lorentz transformation equations,** are (see Appendix E):

$$t_{Be} = \gamma\left(t_{Ae} - \frac{v_{ABx}}{c_0^2}x_{Ae}\right) \tag{14.29}$$

$$x_{Be} = \gamma(x_{Ae} - v_{ABx}t_{Ae}) \tag{14.30}$$

$$y_{Be} = y_{Ae} \tag{14.31}$$

$$z_{Be} = z_{Ae}. \tag{14.32}$$

At nonrelativistic speeds, these equations reduce to the Galilean transformation equations.

From the Lorentz transformation equations, we obtain that the x component of the velocity of an object o in reference frame A, v_{Aox}, is related to that in reference frame B, v_{Box}, by the expression (see Appendix E)

$$v_{Box} = \frac{v_{Aox} - v_{ABx}}{1 - \dfrac{v_{ABx}}{c_0^2}v_{Aox}}. \tag{14.33}$$

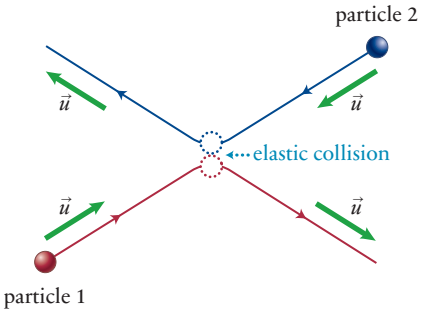
For nonrelativistic speeds, the denominator is approximately equal to 1 and we obtain the usual addition of velocities: $v_{Box} = v_{Aox} - v_{ABx}$ (see Eq. 6.9).

14.16 A car travels 1.0 km down a straight road at 100 km/h. How much shorter is the road in the car's reference frame?

14.7 Conservation of momentum

In Chapter 4 we introduced inertia to account for velocity changes in collisions and took the momentum of a particle to be the product of its inertia and its velocity. This approach led us to conservation of momentum, one of the fundamental principles that we have used throughout this text. In Section 14.4 we found that inertia depends on energy and therefore on speed. Because conservation principles are fundamental and because they embody an appealing simplicity, we would like to preserve them in light of the modifications required by special relativity. To this end, we begin again by taking the momentum of a particle as the product of its inertia and its velocity but this time allowing the inertia to depend on velocity:

$$\vec{p} \equiv m_v\vec{v}. \tag{14.34}$$



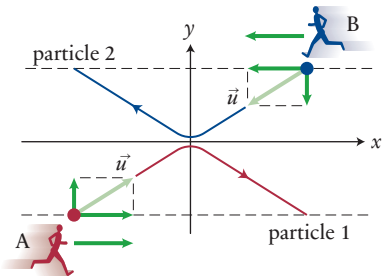
The subscript v on the inertia symbol m_v is there to remind us that inertia is no longer an invariant. We now examine what modifications are needed to our concept of inertia to preserve conservation of momentum.

To obtain an expression for m_v, let us look at an elastic collision between two identical particles and require the system to be isolated so that the momentum of the two particles remains constant. The particles are projected at each other at speed u (**Figure 14.31**). Their velocities are equal in magnitude but opposite in direction, both before and after the collision. The position of the center of mass of this system is at the location where the particles collide and it remains at rest. In other words, Figure 14.31 represents the collision viewed from the zero-momentum reference frame. We begin our analysis of this collision by choosing our axes as shown in **Figure 14.32*a***.

In the zero-momentum reference frame, the speeds of the particles are the same before and after the collision, and so we gain no information on how inertia depends on speed. Let us therefore consider the same collision from the point of view of an observer A moving parallel to the x axis of Figure 14.32 with a velocity equal to the component of the velocity of particle 1 along the x axis. To this observer, particle 1 moves up and down parallel to the y axis (Figure 14.32*b*). For convenience, let's denote the event when particle 1 leaves observer A as the *throw* and its return to observer A as the *catch*.

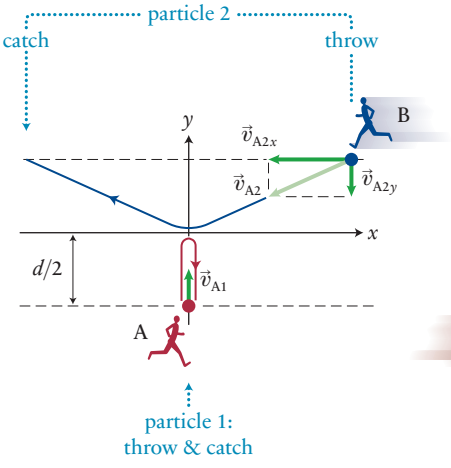
To an observer B moving along the x axis with a velocity equal to the component of the velocity of particle 2 along the x axis, the collision looks exactly the same except that particles 1 and 2 are interchanged (Figure 14.32*c*).

Figure 14.31 Collision between two identical particles as seen in the zero-momentum reference frame.



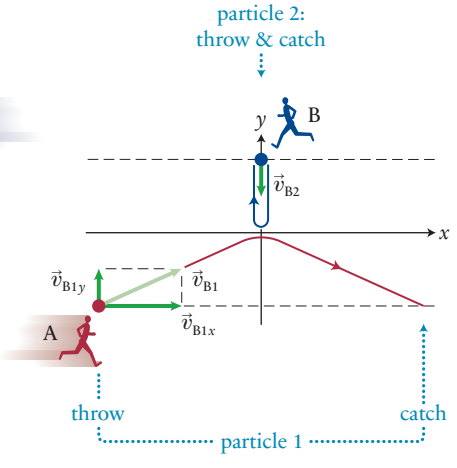
14.17 In Figure 14.32, is the time interval between the throw and the catch of particle 1 in reference frame A greater than, equal to, or less than the time interval between the throw and the catch of particle 2 in reference frame B?

Note that in all three reference frames only the y components of $\vec{v}_1$ and $\vec{v}_2$ change. Because the observers' motion is always in the x direction, there is no length contraction in the y direction, and so to both observers the particles travel the same distance d in the y direction between throw and catch.



In reference frame A, the y component of the velocities of the two particles have the same magnitudes, but the x components are different. Therefore particles 1 and 2 move at different speeds v_1 and v_2, respectively, and so even though we began by declaring the two particles to be identical, the inertia m_{v1} of particle 1 measured in reference frame A must

Figure 14.32 Analysis of the trajectories in Figure 14.31 from three reference frames, showing our choice of axes.



(*a*) **Zero-momentum reference frame**

(*b*) **Observer A's reference frame**

(*c*) **Observer B's reference frame**

be different from the inertia m_{v2} of particle 2 measured in this frame. We can obtain the ratio of these inertias by requiring the momentum of the two-particle system to remain constant. To this end, let us evaluate the velocity changes caused by the collision in reference frame A. Let the time intervals between the throw and catch of particles 1 and 2 in reference frame A be Δt_{A1} and Δt_{A2}, respectively. The changes in the y component of the velocities in reference frame A are thus

$$\Delta v_{A1y} = -\frac{d}{\Delta t_{A1}} \quad \text{and} \quad \Delta v_{A2y} = \frac{d}{\Delta t_{A2}}. \tag{14.35}$$

The time interval Δt_{A1} measured by observer A between the throw and catch of particle 1 in reference frame A is the proper time interval between these two events because they occur at the same position according to observer A: $\Delta t_{A1} = \Delta t_{\text{proper}}$. The time interval Δt_{A2} observer A measures between the throw and catch of particle 2, however, is not a proper time interval because for observer A these two events occur at different positions (Figure 14.32*b*).

Relative to observer B, the throw and catch of particle 2 occur at the same position (Figure 14.32*c*), and so the time interval measured by B is the proper time interval. Because of symmetry, the collision seen by observer A is identical to that seen by observer B, and so the proper time interval measured by A between the throw and catch of particle 1 is equal to the proper time interval measured by B between the throw and catch of particle 2, as you saw in Checkpoint 14.17:

$$\Delta t_{A1} = \Delta t_{B2} = \Delta t_{\text{proper}}. \tag{14.36}$$

Equation 14.13, $\Delta t_v = \gamma \Delta t_{\text{proper}}$, tells us that if observer B measures the proper time interval between the throw and catch of particle 2, observer A moving relative to B obtains that the time interval between those events is $\gamma \Delta t_{\text{proper}}$, where γ depends on the relative velocity of A and B. Therefore

$$\Delta t_{A2} = \gamma \Delta t_{\text{proper}}, \tag{14.37}$$

where v in $\gamma = 1/\sqrt{1 - v^2/c_0^2}$ is the speed of B relative to A: $v = |\vec{v}_{A2x}|$. Substituting Eq. 14.36 into Eq. 14.37 yields $\Delta t_{A2} = \gamma \Delta t_{A1}$, and so Eq. 14.35 becomes

$$\Delta v_{A1y} = -\frac{d}{\Delta t_{A1}} \quad \text{and} \quad \Delta v_{A2y} = \frac{d}{\gamma \Delta t_{A1}}. \tag{14.38}$$

Because the two-particle system is isolated, the sum of the particles' momentum changes in reference frame A must add to zero:

$$\begin{aligned} \Delta p_{A1y} + \Delta p_{A2y} &= m_{v1} \Delta v_{A1y} + m_{v2} \Delta v_{A2y} \\ &= -m_{v1} \frac{d}{\Delta t_{A1}} + m_{v2} \frac{d}{\gamma \Delta t_{A1}} = 0, \end{aligned} \tag{14.39}$$

which means that in reference frame A,

$$m_{v2} = \gamma m_{v1}. \tag{14.40}$$

According to observer A, the inertia of particle 2 is greater than the inertia of particle 1.

14.18 (*a*) According to observer A in Figure 14.32, which particle is moving faster? (*b*) Does A conclude that the inertia of a particle increases or decreases with speed? (*c*) Answer these two questions for observer B.

QUANTITATIVE TOOLS

Equation 14.40 gives us the relationship between the inertias of two particles moving relative to each other and relative to us. To determine the relationship between the inertia of a particle moving relative to us and that of an identical particle at rest relative to us, consider the limit in which the y components of the velocities are very small. In that case, particle 1 in Figure 14.32*b* is virtually at rest in reference frame A, $v_{A1} \approx 0$, and particle 2 moves horizontally along with observer B at speed $v_{A2} \approx |\vec{v}_{A2x}| = v$. When the particle is at rest relative to us, its inertia and mass are equivalent and so $m_v \approx m$, where m is the mass of the particle. If we denote the inertia of the moving particle by m_v, Eq. 14.40 shows us how a particle's **inertia** m_v, which depends on speed, is related to its mass m, which is an invariant:

$$m_v = \gamma m. \tag{14.41}$$

The first thing to note is that for speeds up to about $0.1c_0$, $\gamma \approx 1$, and so mass and inertia are virtually indistinguishable, in agreement with what we established in Chapter 13. As the speed approaches c_0, however, m_v increases to infinity. Because inertia is a measure of an object's resistance to being accelerated, m_v approaching infinity means it becomes more and more difficult to speed up the particle as its speed approaches c_0. We therefore must conclude that no object or particle that has mass can be accelerated to speed c_0.

EXERCISE 14.10 Sluggish electron

By what factor does the inertia of an electron increase (*a*) as the electron is accelerated from rest to $\frac{1}{3}c_0$ and (*b*) as its speed is increased by another 20%? (*c*) Does the mass of the electron change as it is accelerated?

SOLUTION From Eq. 14.41, I know that the factor by which the inertia increases is $m_v/m = \gamma$. (*a*) At $\frac{1}{3}c_0$, $\gamma = 1/\sqrt{1-\left(\frac{1}{3}\right)^2} = 1.06$. The inertia increases by 6%. ✔

(*b*) Increasing the speed by another 20% means adding

$$\tfrac{1}{5}\left(\tfrac{1}{3}c_0\right) = \tfrac{1}{15}c_0$$

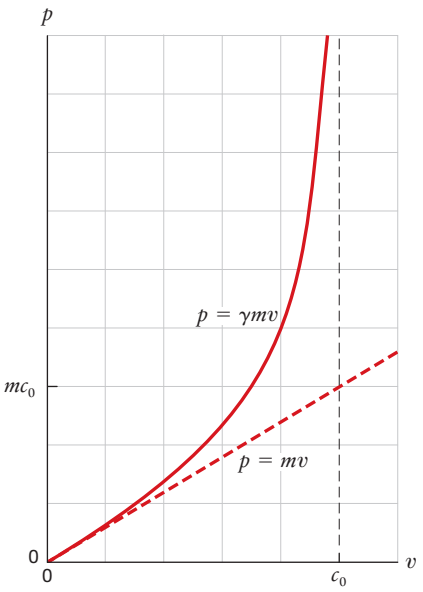
to the speed $\frac{1}{3}c_0$, giving

$$v = \tfrac{1}{3}c_0 + \tfrac{1}{15}c_0 = \tfrac{2}{5}c_0$$

$$\gamma = \frac{1}{\sqrt{1-\left(\frac{2}{5}\right)^2}} = 1.09.$$

The inertia of the electron increases by another 3%. ✔

(*c*) No. Mass is an invariant. Thus the mass of an object is independent of the motion of either the observer or the object. ✔



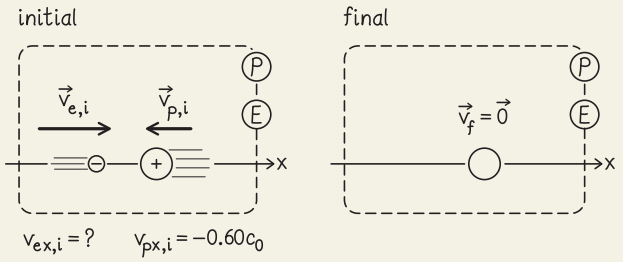
14.19 To what fraction of c_0 must an electron at rest in the Earth reference frame be accelerated in order for its inertia to increase by a factor of 1000?

Now that we have an expression for the inertia of a moving particle (Eq. 14.41), we can obtain an expression for the particle's momentum in terms of its mass and velocity. Substituting Eq. 14.41 into Eq. 14.34 gives

$$\vec{p} = \gamma m\vec{v}. \tag{14.42}$$

Unlike the expression for momentum you learned in Chapter 4, $\vec{p} = m\vec{v}$, Eq. 14.42 does not show the momentum increasing linearly with increasing velocity. At ordinary speeds, Eq. 14.42 reduces to the familiar form $\vec{p} = m\vec{v}$. As the speed approaches c_0, the momentum increases rapidly to infinity (**Figure 14.33**). Experiments such as the one described in the next example have conclusively shown that Eq. 14.42 correctly accounts for the momentum of a particle at all speeds up to c_0.

Figure 14.33 As the speed of a particle approaches c_0, the magnitude of its momentum approaches infinity. Up to a speed of about $0.1c_0$, the magnitude of the momentum is very close to mv.



EXAMPLE 14.11 Fast collision

A fast-moving electron collides head-on with a proton moving at $0.60c_0$ as measured in the Earth reference frame. What is the electron's initial speed if the two particles combine to form a system that after the collision is at rest in the Earth reference frame? The mass of the proton is 1836 times that of the electron.

1 GETTING STARTED I begin by making a sketch showing the electron-proton system before and after the collision (**Figure 14.34**). I choose the positive x axis to be in the initial direction of motion of the electron. I can consider the electron-proton system to be isolated, and so the initial momentum of the system must be equal to the final momentum (which is zero).

Figure 14.34

2 DEVISE PLAN I can use Eq. 14.42 to calculate the initial momentum of each particle and then set the sum of these momenta equal to zero. The resulting expression contains four quantities: the unknown initial velocity component $v_{ex,i}$ of the electron, the initial velocity component $v_{px,i}$ of the proton ($-0.60c_0$), the mass m_p of the proton, and the mass m_e of the electron. Because I am given that $m_p/m_e = 1836$, I can solve for the unknown initial velocity of the electron.

3 EXECUTE PLAN The initial momentum of the system must be zero, so

$$p_{px,i} + p_{ex,i} = \gamma_{p,i} m_p v_{px,i} + \gamma_{e,i} m_e v_{ex,i} = 0, \qquad (1)$$

where I have added subscripts to the Lorentz factors to keep the factor for the proton separate from the factor for the electron. Dividing the two terms containing γ in Eq. 1 by m_e, and using Eq. 14.6 to write out the Lorentz factors, I can rewrite Eq. 1 as

$$\frac{m_p}{m_e}\frac{v_{px,i}}{\sqrt{1 - v_{px,i}^2/c_0^2}} = -\frac{v_{ex,i}}{\sqrt{1 - v_{ex,i}^2/c_0^2}}.$$

When I square both sides and then substitute the values for the mass ratio and the speed of the proton, I get

$$(1836)^2\frac{(-0.60c_0)^2}{1-(-0.60)^2} = \frac{v_{ex,i}^2}{1-(v_{ex,i}/c_0)^2},$$

which I can solve for $v_{ex,i}$:

$$v_{ex,i} = (1 + 5.3 \times 10^{-7})^{-1/2} c_0 = 0.99999974\ c_0. \checkmark$$

I show eight significant digits because the 1 in the above expression is exact (infinite number of significant digits) and so the sum $1 + 5.3 \times 10^{-7}$ is known to the eighth decimal place (1.00000053).

4 EVALUATE RESULT I note that this speed is close to c_0 (but not greater than or equal to it). The fact that the electron needs to travel at such a high speed is not surprising because the proton's mass is nearly 2000 times that of the electron.

14.20 In Example 14.11, (*a*) is the collision elastic, inelastic, or totally inelastic (see Section 5.1)? (*b*) How fast would the electron have to move if the expression for momentum were $\vec{p} = m\vec{v}$ instead of Eq. 14.42?

14.8 Conservation of energy

Now we turn our attention to energy. Suppose we accelerate a particle from rest to a speed approaching c_0.* To determine the increase in its kinetic energy, let us calculate the work done on the particle. From Chapter 9, we know that the work done on the particle is given by Eq. 9.22:

$$W = \int_{x_i}^{x_f} F(x)\,dx = \int_{x_i}^{x_f} \frac{dp}{dt}dx, \qquad (14.43)$$

where we have substituted the definition of force (Eq. 8.4). Substituting $p = \gamma mv$ and noting that the mass m is constant, we can write the integrand in Eq. 14.43 as

$$\frac{dp}{dt}dx = \frac{d}{dt}(\gamma mv)dx = m\frac{d(\gamma v)}{dt}dx. \qquad (14.44)$$

*From here on, speeds are assumed to be relative to the Earth reference frame unless stated otherwise.

QUANTITATIVE TOOLS

Note that because γ is a function of v, it varies with time and cannot be pulled out of the differentiation. Using $dx = v\,dt$ and canceling the dt factors, we get

$$\frac{dp}{dt}dx = m\frac{d(\gamma v)}{dt}dx = m\frac{d(\gamma v)}{dt}v\,dt = mv\,d(\gamma v), \qquad (14.45)$$

and so the work done on the particle is

$$W = m\int_{\text{i}}^{\text{f}} v\,d(\gamma v) = m\int_{\text{i}}^{\text{f}} (v^2\,d\gamma + v\gamma\,dv), \qquad (14.46)$$

where we have used the chain rule $d(\gamma v) = \gamma\,dv + v\,d\gamma$ (Appendix B).

The relationship between v^2 and γ is given by Eq. 14.9: $v^2/c_0^2 = 1 - 1/\gamma^2$. Differentiating both sides of Eq. 14.9 with respect to time yields

$$\frac{2v}{c_0^2}\frac{dv}{dt} = 0 - \frac{-2}{\gamma^3}\frac{d\gamma}{dt}, \qquad (14.47)$$

and then multiplying both sides by $\frac{1}{2}c_0^2\gamma\,dt$ yields

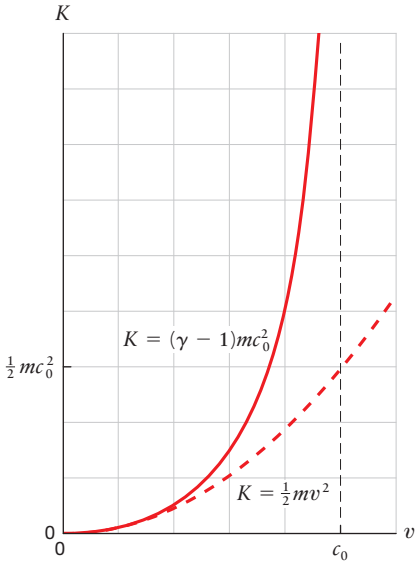
$$\gamma v\,dv = \frac{c_0^2}{\gamma^2}d\gamma. \qquad (14.48)$$

From Eq. 14.8, $1/\gamma^2 = 1 - v^2/c_0^2$, we can say

$$\frac{1}{\gamma^2} = \frac{c_0^2 - v^2}{c_0^2} \quad \text{and} \quad \frac{c_0^2}{\gamma^2} = c_0^2 - v^2, \qquad (14.49)$$

and so c_0^2/γ^2 in Eq. 14.48 can be replaced by $c_0^2 - v^2$, yielding $\gamma v\,dv = (c_0^2 - v^2)d\gamma$. Substituting this result into Eq. 14.46 and noting that $\gamma = 1$ when $v = 0$ at the lower integration boundary, we get

$$W = m\int_1^{\gamma} [v^2\,d\gamma + (c_0^2 - v^2)d\gamma] = mc_0^2\int_1^{\gamma} d\gamma = (\gamma - 1)mc_0^2. \qquad (14.50)$$



All of this work done on the particle goes toward increasing its kinetic energy, and so the particle's final **kinetic energy** is

$$K = (\gamma - 1)mc_0^2 = \gamma mc_0^2 - mc_0^2 = m_v c_0^2 - mc_0^2, \qquad (14.51)$$

where we have used the expression for the inertia, $m_v = \gamma m$, from Eq. 14.41.

This expression for the kinetic energy of a particle looks completely different from the expression we have used so far, $K = \frac{1}{2}mv^2$ (see Section 5.2). In particular, as the speed approaches c_0, the particle's kinetic energy becomes infinitely great (**Figure 14.35**). Therefore it would take an infinite amount of energy to accelerate a particle to speed c_0, so c_0 is the limiting speed at which any object can travel relative to another object.

Figure 14.35 As the speed of a particle approaches c_0, its kinetic energy approaches infinity. Up to speeds of about $0.25c_0$, the kinetic energy is very close to $\frac{1}{2}mv^2$.

14.21 Use Eq. 14.11, $\gamma - 1 \approx 0.5(v^2/c_0^2)$, to show that Eq. 14.51 reduces to the familiar $K = \frac{1}{2}mv^2$ at nonrelativistic speeds ($v \ll c_0$).

Each term on the right of Eq. 14.51 represents a quantity of energy, so Eq. 14.51 gives us the kinetic energy of a particle as the difference between two amounts of energy. In Chapter 5 we defined the energy of a system as the sum of that system's kinetic and internal energies, $E \equiv K + E_{\text{int}}$

(Eq. 5.21), and so we see that the kinetic energy of a system is obtained by subtracting the internal energy from the system's energy:

$$K = E - E_{\text{int}}. \tag{14.52}$$

In the right side of Eq. 14.51, note that the first term in the difference is proportional to inertia m_v and the second is proportional to mass m. In Section 14.4 we established that there is a relationship between inertia and energy and a relationship between mass and internal energy. Comparing Eqs. 14.51 and 14.52 thus suggests that the energy is given by

$$E = m_v c_0^2 \tag{14.53}$$

and the **internal energy** is given by

$$E_{\text{int}} = mc_0^2. \tag{14.54}$$

The assignment made in Eqs. 14.53 and 14.54 may look like a leap of faith, but in Section 14.4 we found that in a nuclear reaction between a proton and a deuteron, both the internal energy and the mass of the system decrease. Equation 14.54 tells us that the changes in internal energy and mass should be related as

$$\begin{aligned}\Delta E_{\text{int}} &= E_{\text{int,f}} - E_{\text{int,i}} \\ &= m_{\text{f}} c_0^2 - m_{\text{i}} c_0^2 = \Delta m c_0^2,\end{aligned} \tag{14.55}$$

or $\Delta E_{\text{int}}/\Delta m = c_0^2$. The experimental data show that the ratio $\Delta E_{\text{int}}/\Delta m = c_0^2$ is $8.98 \times 10^{16}\ \text{m}^2/\text{s}^2$ (see Example 14.5), which is precisely c_0^2, confirming Eq. 14.54. The term E_{int} in Eq. 14.54 thus represents the energy that corresponds to *all* of the mass of the particle.

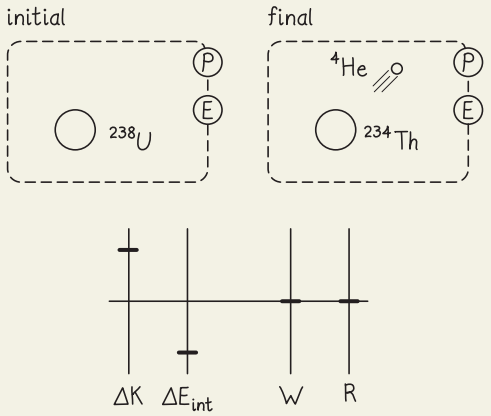
All forms of internal energy we have discussed so far require an arbitrary choice of reference point (see, for example, Eq. 7.21), and so we usually considered only differences in internal energy. Equation 14.54, however, provides us with a measure of internal energy that does not depend on any choice of reference point. What is more, we can calculate E_{int} from the mass m, which is a quantity we can determine experimentally.

For example, a proton, as mentioned in Chapter 7, is made up of quarks held together by the strong nuclear interaction. If we add up the values of the masses of these quarks (which are determined from a combination of theory and experiment and known only approximately), we discover that their sum is just 1% of the mass of the proton. The remaining 99% of the mass of the proton must therefore come from the nuclear potential energy that binds the quarks together. Because protons (and neutrons, which also consist of three quarks) are the basic building blocks of all matter, it follows that most of what we consider matter really *is* energy! Even though we have no mathematical expression for nuclear potential energy, we can determine its value from the masses of the proton and the quarks, and the relationship $E_{\text{int}} = mc_0^2$.

14.22 (*a*) Draw a simplified energy diagram for the totally inelastic collision between two identical objects moving at speed v toward each other. After the collision, the two objects form a compound object that is at rest. (*b*) Which of the following quantities are constant in the collision: kinetic energy, mass, energy?

QUANTITATIVE TOOLS

EXAMPLE 14.12 Alpha emission



A uranium nucleus ^{238}U at rest decays to a thorium nucleus ^{234}Th by emitting an alpha particle (which is a helium nucleus ^{4}He):

$$^{238}\text{U} \rightarrow {}^{234}\text{Th} + {}^{4}\text{He}.$$

The mass of the uranium atom is $m_U = 395.292632 \times 10^{-27}$ kg, the mass of the thorium atom is $m_{Th} = 388.638541 \times 10^{-27}$ kg, and the mass of the helium atom is $m_{He} = 6.646479 \times 10^{-27}$ kg. What is the combined kinetic energy of the fragments?

1 GETTING STARTED I begin by drawing a simplified energy diagram for the alpha emission (**Figure 14.36**), choosing the uranium nucleus and the fragments as my (closed) system. Because the system is closed, the change in kinetic energy is the negative of the change in internal energy: $\Delta K = -\Delta E_{int}$.

Figure 14.36

2 DEVISE PLAN Because the initial kinetic energy is zero, the final kinetic energy of the fragments is equal to $-\Delta E_{int}$. To determine this change in internal energy, I can calculate the change in the mass of the system and then use Eq. 14.55.

3 EXECUTE PLAN

$$\Delta m = (m_{Th} + m_{He}) - m_U = -7.61 \times 10^{-30} \text{ kg}.$$

Substituting this value into Eq. 14.55 yields

$$\Delta E_{int} = \Delta m c_0^2 = (-7.61 \times 10^{-30} \text{ kg})(3.00 \times 10^8 \text{ m/s})^2$$

$$= -6.85 \times 10^{-13} \text{ J},$$

so the final kinetic energy of the fragments is 6.85×10^{-13} J. ✔

4 EVALUATE RESULT The answer I obtain is a tiny amount of energy, contrary to my expectations for nuclear energy! However, this is the energy liberated by the nucleus of a single atom. One atom is about 10^{-10} m in diameter, which means a cube of matter 1 mm on a side contains about $[(10^{-3} \text{ m})/(10^{-10} \text{ m})]^3 = 10^{21}$ atoms. If each atom liberates an amount of energy equal to the answer I got, my cube yields $(10^{21})(6.85 \times 10^{-13} \text{ J}) = 7 \times 10^8$ J of energy, which is a very large amount and more in line with what I'd expect.

14.23 An atom in the filament of a light bulb emits energy in the form of light. (*a*) Draw a simplified energy diagram representing this emission. (*b*) Does the mass of the atom increase, decrease, or stay the same? (*c*) Does the inertia of the atom increase, decrease, or stay the same? Assume the atom remains at rest in the Earth reference frame.

We can obtain a useful relationship from our expressions for momentum, $\vec{p} = \gamma m \vec{v}$ (Eq. 14.42), and energy, $E = m_v c_0^2$ (Eq. 14.53), by evaluating the quantity $E^2 - (c_0 p)^2$. Substituting γm for m_v in Eq. 14.53, we have

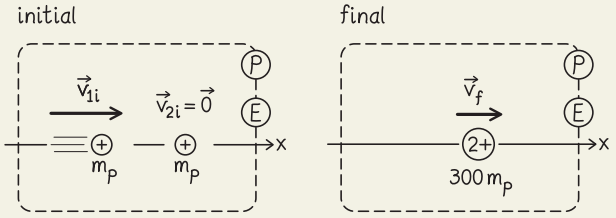
$$E^2 - (c_0 p)^2 = \gamma^2 m^2 c_0^4 - c_0^2 \gamma^2 m^2 v^2 = \gamma^2 m^2 c_0^2 (c_0^2 - v^2). \quad (14.56)$$

From Eq. 14.49, we see that $c_0^2 - v^2 = c_0^2/\gamma^2$, and so

$$E^2 - (c_0 p)^2 = (m c_0^2)^2. \quad (14.57)$$

The right side of this expression is an invariant, and so its value does not depend on the reference frame. The left side, however, contains the energy E and the momentum magnitude p of the system under consideration, both of which depend on the reference frame! Again, we have constructed an invariant from two quantities that are not invariants themselves. Equation 14.57 tells us that if we measure the energy and the magnitude of the momentum of a system in a certain reference frame and then compute the quantity $E^2 - (c_0 p)^2$, we obtain the same value as the corresponding

combination in any other reference frame. In each case, the result is equal to $(mc_0^2)^2$, and so the quantity $E^2 - (c_0p)^2$ is an invariant.



Energy and momentum are conserved quantities when evaluated with respect to each reference frame, and so for a system that is both isolated and closed, the energy and momentum laws tell us that $E_i = E_f$ and $\vec{p}_i = \vec{p}_f$. We have used these equations extensively to determine E_f and p_f given E_i and p_i. Equation 14.57 relates values of E and p to values of m. Because values of m are known from separate measurements, Eq. 14.57 allows us to eliminate momentum from the problem. The next example and checkpoint illustrate the usefulness of Eq. 14.57.

EXAMPLE 14.13 Proton collision

Two protons, each of mass $m_p = 1.67 \times 10^{-27}$ kg, collide to produce a particle that has a mass 300 times the mass of each proton. What is the minimum kinetic energy that one of the protons must have in order to create this particle if the other proton is initially at rest?

1 GETTING STARTED I begin by organizing the information in a sketch (**Figure 14.37**). I denote the incoming proton by 1 and the proton initially at rest by 2. The two protons form an isolated, closed system, and so the energy law requires $E_{1i} + E_{2i} = E_f$ and the momentum law requires $\vec{p}_{1i} = \vec{p}_f$ (because $\vec{p}_{2i} = 0$).

Figure 14.37

2 DEVISE PLAN The initial kinetic energy K_{1i} of proton 1 is given by Eq. 14.52, with the internal energy E_{1int} given by Eq. 14.54. I must therefore determine the initial energy E_{1i} of proton 1. I can use Eq. 14.57 to relate the energy E of each particle to its momentum p and then combine this with the energy and momentum law to solve for the initial energy of proton 1.

3 EXECUTE PLAN Applying Eq. 14.57 to proton 1, proton 2, and the final particle, I get

$$E_{1i}^2 - (c_0p_{1i})^2 = (m_pc_0^2)^2 \quad (1)$$

$$E_{2i}^2 = (m_pc_0^2)^2 \quad (2)$$

$$E_f^2 - (c_0p_f)^2 = (300m_pc_0^2)^2. \quad (3)$$

Substituting $E_{1i} + E_{2i} = E_f$ and $p_{1i} = p_f$ into Eq. 3 yields

$$(E_{1i} + E_{2i})^2 - (c_0p_{1i})^2 = (300m_pc_0^2)^2.$$

Working out the left side, I get

$$E_{1i}^2 + 2E_{1i}E_{2i} + E_{2i}^2 - (c_0p_{1i})^2 = E_{1i}^2 - (c_0p_{1i})^2 + E_{2i}^2 + 2E_{1i}E_{2i}$$

$$= (300m_pc_0^2)^2,$$

so, after substituting from Eqs. 1 and 2, I have

$$(m_pc_0^2)^2 + (m_pc_0^2)^2 + 2E_{1i}(m_pc_0^2) = (300m_pc_0^2)^2.$$

Solving for E_{1i} gives

$$E_{1i} = \frac{(300m_pc_0^2)^2 - 2(m_pc_0^2)^2}{2(m_pc_0^2)} = \tfrac{1}{2}(300^2 - 2)m_pc_0^2. \quad (4)$$

From Eqs. 14.52 and 14.54, I have $K_{1i} = E_{1i} - m_pc_0^2$, so

$$K_{1i} = \left[\tfrac{1}{2}(300^2 - 2)m_pc_0^2\right] - m_pc_0^2 = \tfrac{1}{2}(300^2 - 4)m_pc_0^2$$

$$= \tfrac{1}{2}(300^2 - 4)(1.67 \times 10^{-27}\text{ kg})(3.00 \times 10^8\text{ m/s})^2$$

$$= 6.76 \times 10^{-6}\text{ J}. \checkmark$$

4 EVALUATE RESULT My answer is large for a particle that has a mass on the order of 10^{-27} kg. Comparing my result in Eq. 4 with Eq. 14.51, however, I see that $\gamma - 1 = (300^2 - 4)/2$, or $\gamma = 4.5 \times 10^4$, and so the proton has to be accelerated to very close to the speed of light. It is therefore not unreasonable that the energy of the proton is on the order of microjoules.

14.24 In Example 14.13, what is the minimum kinetic energy of each proton if they have the same initial speed and collide head-on?

QUANTITATIVE TOOLS

Chapter Summary

Time measurements (Sections 14.1, 14.2)

Concepts An **event** is a physical occurrence that takes place at a specific location at a specific instant.

Two events are **simultaneous** when they are observed to occur at the same instant in a reference frame made up of a grid of synchronized clocks. Events that are simultaneous in one reference frame need not be simultaneous in another reference frame moving relative to the first one.

An **invariant** is a quantity whose value does not depend on the choice of reference frame.

The **speed of light** is independent of the motion of the light source relative to any moving observer. Therefore the speed of light is an invariant. It is the limiting speed of any object moving relative to any other object.

Quantitative Tools In SI units, the speed of light in vacuum is $c_0 = 3.00 \times 10^8$ m/s.

Space-time (Sections 14.3, 14.5, 14.6)

Concepts The **proper time interval,** Δt_{proper}, is the time interval between two events that occur at the same position in a particular reference frame but at different instants. An observer measuring the proper time interval between two events records the shortest time interval between those events.

Time dilation: A clock moving relative to an observer is measured to be running more slowly than an identical clock at rest relative to that observer.

The **proper length,** ℓ_{proper}, of an object is the length of that object measured by an observer who is at rest relative to the object.

Length contraction: When an object moves at speed v relative to an observer, the observer measures the length ℓ_v of the object along the direction of its motion to be shorter than the proper length of the object.

Quantitative Tools For an object moving at speed v, the **Lorentz factor** γ is a measure of the extent to which relativity affects our everyday notions of length and time intervals:

$$\gamma \equiv \frac{1}{\sqrt{1 - v^2/c_0^2}}. \tag{14.6}$$

At nonrelativistic speeds ($v \leq 0.1c_0$), $\gamma \approx 1$, but it approaches infinity as v approaches c_0.

Time dilation: If Δt_{proper} is the proper time interval between two events measured by an observer for whom the two events occur at the same position but at different instants, then the time interval Δt_v between those events measured by an observer moving at speed v relative to the observer is

$$\Delta t_v = \gamma \Delta t_{\text{proper}}. \tag{14.13}$$

The **space-time interval** s^2 between two events that are separated by a time interval Δt and a space interval Δx is given by

$$s^2 \equiv (c_0 \Delta t)^2 - (\Delta x)^2. \tag{14.18}$$

If an object that has proper length ℓ_{proper} moves at speed v relative to an observer, that observer measures the length ℓ_v of the object to be

$$\ell_v = \frac{\ell_{\text{proper}}}{\gamma}. \tag{14.28}$$

The **Lorentz transformation equations** are relationships between the coordinates of an event e measured in two reference frames A and B that coincide at $t_A = t_B = 0$ and are moving in the x direction at constant velocity $\vec{v}_{AB}$ relative to each other:

$$t_{Be} = \gamma\left(t_{Ae} - \frac{v_{ABx}}{c_0^2} x_{Ae}\right) \tag{14.29}$$

$$x_{Be} = \gamma(x_{Ae} - v_{ABx} t_{Ae}) \tag{14.30}$$

$$y_{Be} = y_{Ae} \tag{14.31}$$

$$z_{Be} = z_{Ae}. \tag{14.32}$$

Velocity addition: From the Lorentz transformation equations, we find that v_{Aox}, the x component of the velocity of an object o measured in reference frame A, is related to v_{Box}, the x component of its velocity measured in reference frame B, by

$$v_{Box} = \frac{v_{Aox} - v_{ABx}}{1 - \frac{v_{ABx}}{c_0^2} v_{Aox}}. \tag{14.33}$$

Energy and momentum (Sections 14.4, 14.7, 14.8)

Concepts The internal energy E_{int} of an object (energy not associated with the object's motion) is an invariant and is proportional to the object's mass m (the property that determines its gravitational interaction). Mass is also an invariant.

Unlike mass, inertia (a quantitative measure of an object's tendency to resist any change in its velocity) is not an invariant: What an observer measures for an object's inertia depends on the motion of the observer relative to the object.

Quantitative Tools For an object of mass m, its inertia m_v is

$$m_v = \gamma m, \tag{14.41}$$

its momentum $\vec{p}$ is

$$\vec{p} = \gamma m \vec{v}, \tag{14.42}$$

and its kinetic energy K is

$$K = (\gamma - 1) m c_0^2. \tag{14.51}$$

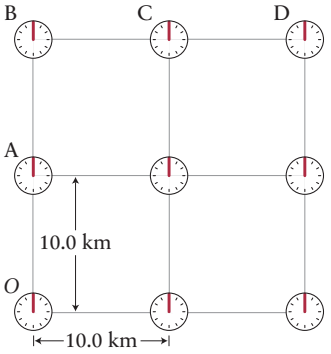
The energy E of an object of mass m and inertia m_v is

$$E = m_v c_0^2, \tag{14.53}$$

and its internal energy E_{int} is

$$E_{int} = m c_0^2. \tag{14.54}$$

Questions and Problems



For instructor-assigned homework, go to Mastering Physics

Dots indicate difficulty level of problems: • = *easy*, •• = *intermediate*, ••• = *hard*; CR = *context-rich problem.*

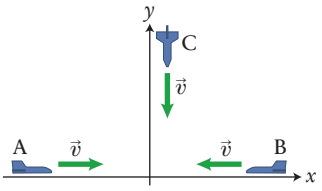
14.1 Time measurements

1. Which of the following are events? (*a*) The local television station's newscast runs from 11:00 to 11:30 p.m. (*b*) The ceremonial first pitch is thrown at a baseball game in Omaha, Nebraska. (*c*) The Perseid meteor shower is seen across the eastern coast of North America. (*d*) A rainstorm lasts all day in Kyoto, Japan. (*e*) Two cars crash in front of your home. (*f*) An all-night concert starts in a local park. (*g*) Light emitted by a supernova reaches a spherical shell of radius 40,000 light years relative to its source. (One light year is the distance light travels in one year.) •
2. You are in a rocket moving away from Earth at one-third the speed of light relative to Earth. A friend is on Earth, and an astronaut in another rocket is moving toward Earth at one-third the speed of light (in the Earth reference frame), on a path collinear with your path. If each of you records the duration of your journey in your three respective reference frames, which of you records the proper time interval? •
3. A set of atomic clocks is placed on a square grid as shown in Figure P14.3. In order to synchronize these clocks, you set the time on each to a certain reading before they are allowed to run. Clock O starts first, and at precisely 12:00 noon, it sends out a light pulse in all directions. Each of the other clocks starts running as soon as the pulse reaches it. What initial time should you use for clocks A, B, C, and D to synchronize them with clock O? Express your answer to the nearest microsecond before or after 12:00 noon. ••

Figure P14.3

4. Events 1 and 2 are exploding firecrackers that each emit light pulses. In the reference frame of the detector, event 1 leaves a char mark at a distance 3.40 m from the detector, and event 2 leaves a similar mark at a distance 2.10 m from the detector. If the two events are simultaneous in the reference frame of the detector and occur at instant $t = 0$, at what instant of time will each light pulse be detected? ••
5. Consider the grid of clocks in Figure 14.6. Do observers stationed at clocks far from the reference clock read earlier, later, or the same time as the time on the reference clock (*a*) if the clocks are to be synchronized after a pulse is sent out activating them but this pulse has not yet been sent, and (*b*) if the pulse has been sent out and all clocks are running? (*c*) Suppose the pulse has been sent and all clocks are running. If you stand at the reference clock and use a telescope to read the time on distant clocks, do you read a time earlier, later, or the same as the time on the reference clock? ••
6. Observers A and B are both at rest in the Earth reference frame, in different parts of a large city, awaiting the start of a fireworks show. They want to synchronize their atomic clocks for some experiments to be conducted later that evening. A and B plan to start their clock displays at an agreed signal, so each clock display is preset to exactly 10:00 p.m., but they will not record time until the "start" buttons are pressed. Observer A suggests that each of them start upon *seeing* the first firework, and observer B suggests that each of them start upon *hearing* the first firework. (*a*) Which plan leads to the clocks being more closely synchronized, and why? (*b*) Is it possible for the two methods to give the same agreement between clocks? •••

14.2 *Simultaneous* is a relative term



7. Observer A is stationary in the Earth reference frame, and pilot B is flying toward pilot A at relative speed v_{AB}. What speed does observer A measure for the speed of the light emitted by a signal light on pilot B's ship? •
8. Alarm clock 1 is positioned at $x = -d$ and alarm clock 2 at $x = +d$ in reference frame A. According to a clock in reference frame A, both go off at $t = 0$. An observer in reference frame B, which is moving relative to A, measures alarm clock 2 as going off first. In what direction is B moving relative to A? •
9. You are traveling toward a large fixed mirror at a constant relative speed $0.20c_0$. At $t = 0$, when the mirror is a distance d from you (measured in your reference frame), you emit a light pulse from a lantern and then detect the reflected light pulse 0.80 μs later. What is the value of d? ••
10. You are in a jet helicopter traveling horizontally at 180 m/s relative to Earth. At one instant you observe the light pulses from two lightning strikes, one directly ahead of the helicopter and one directly behind it. (*a*) Can you say that the strikes occurred simultaneously in your reference frame? (*b*) How would your answer change if you were instead hovering at rest relative to the ground when you observed the two pulses? (*c*) How would your answer change if the pilot told you that the two strikes occurred at equal distances from the helicopter in the helicopter's reference frame? (*d*) Would an observer on the ground agree with your answers to parts *a*, *b*, and *c*? ••
11. Consider a lightweight, straight, rigid rod that has a proper length of 1×10^6 m. If you rotate the rod at 100 turns/s about a perpendicular axis through its center, at what speed do the ends of the rod move? What prevents such a case from occurring? ••
12. Observer A on Earth sees spaceship B moving at speed $v = 0.600c_0$ away from Earth and spaceship C moving at the same speed in the opposite direction. Observer A determines that both ships simultaneously sent out a radio signal at 12:00:00 noon and another signal at 12:05:00 p.m., making the time interval A measures between the emission of the signals from each ship $\Delta t_A = 5.00$ min. Let Δt_{BB} denote the time interval measured on ship B between the emission of signals on ship B, Δt_{BC} denote the time interval measured on ship B between the emission of signals on ship C, and Δt_{CB} denote the time interval measured on ship C between emission of signals on ship B. (*a*) Is Δt_{BB} greater than, less than, or equal to Δt_A? (*b*) Is Δt_{BC} greater than, less than, or equal to Δt_{CB}? ••

14.3 Space-time

13. An astronaut takes what he measures to be a 10-min nap in a space station orbiting Earth at 8000 m/s. A signal is sent from the station to Earth at the instant he falls asleep, and a second signal is sent to Earth the instant he wakes. Does an observer on Earth measure the astronaut's nap as being shorter than, longer than, or equal to 10 min? •
14. Suppose you could move at nearly the speed of light. If you were to move at this speed for a large portion of your life, would it be possible for you to live long enough to see a later calendar year on Earth than you otherwise would have? Compare your answer with that for Checkpoint 14.8. •
15. Standing somewhere between two vertical mirrors, you hold a lantern and at $t = 0$ emit a light pulse that travels in all directions. You observe the pulse reflected from the mirror on your right at $t = 2.5$ μs and from the mirror on your left at $t = 6.5$ μs. What is the distance between the two mirrors in your reference frame? •
16. A spaceship of proper length $\ell = 100$ m travels in the positive x direction at a speed of $0.800c_0$ relative to Earth. An identical spaceship travels in the negative x direction along a parallel course at the same speed relative to Earth. At $t = 0$, an observer on Earth measures a distance $d = 50{,}000$ km separating the two ships. At what instant does this observer see the leading edges of the two ships pass each other? ••
17. A spacecraft traveling away from Earth at relative speed $0.850c_0$ sends a radio message when it is 65,000,000 km away from Earth in the Earth reference frame. When the signal is received, Earth-based engineers immediately send a reply to the spacecraft. What do these engineers measure for the time interval from the instant the spacecraft sends the original message to the instant the spacecraft receives the reply? ••

18. Spaceships A, B, and C in Figure P14.18 all have the same proper length and all fly with the same speed according to an observer on Earth. Rank the lengths of the three ships as measured by an observer in ship A, longest first. ●●

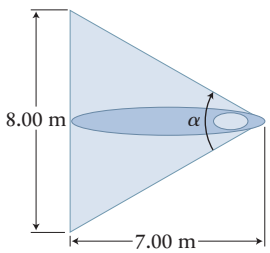
Figure P14.18

19. The boundary of a lunar base is a square 1 km wide and 1 km long in the Moon reference frame. Spaceship A flies at high relative speed close to the Moon parallel to the edge that we shall call the length of the field. Crew A measures the length and width, and reports that the area of the field is 0.5 km^2 in reference frame A. Spaceship B flies with the same relative speed as spaceship A, but parallel to one diagonal of the field. Crew B measures both diagonals. What surface area does crew B calculate in reference frame B? ●●●

14.4 Matter and energy

20. What is the kinetic energy of a pin in your reference frame if you measure its inertia to be three times its mass? ●
21. A golf ball hit from a tee accelerates from rest to a speed of 40.0 m/s relative to the Earth reference frame. By what percent does the mass of the ball increase as it is hit? ●
22. One end of a vertical spring of spring constant $k = 1500$ N/m is attached to the floor. You compress the spring so that it is 2.40 m shorter than its relaxed length, place a 1.00-kg ball on top of the free end, and then release the system at $t = 0$. (All values are measured in the Earth reference frame.) (*a*) By how much does the mass of the spring change during the time interval from $t = 0$ to the instant the ball leaves the spring? (*b*) By how much does the mass of the Earth-ball-spring system change during the time interval from $t = 0$ to the instant the ball reaches its maximum height? ●●
23. You pick up your physics book from the floor and put it on your desk. In the Earth reference frame, which of the following quantities have changed for the system made up of Earth and the book: mass, energy, inertia, kinetic energy? ●●
24. Observer A is on Earth looking at the Moon, and observer B is on the Moon looking at Earth. Which of the following quantities do the observers agree on for the Earth-Moon system: inertia, energy, mass, kinetic energy? ●●
25. How far above Earth's surface must a 10,000-kg boulder be moved to increase the mass of the Earth-boulder system by 2.50 mg? Assume the same ratio of energy change to mass change as in Exercise 14.5(*b*): 8.98×10^{16} J/kg. ●●

14.5 Time dilation



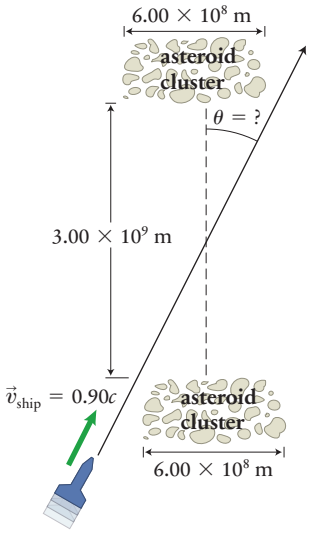
26. A bullet is fired from a rifle (event 1) and then strikes a soda bottle, shattering it (event 2). Is there some inertial reference frame in which event 2 precedes event 1? If so, does the existence of this reference frame violate causality? ●
27. Classify the space-time interval between each pair of events as timelike, spacelike, or lightlike: (*a*) A sunspot erupts on the surface of the Sun and is seen on Earth 500 s later. (*b*) A supernova explodes and is noticed 8.00×10^{20} m away after 8.45×10^4 y by an observer at rest relative to the supernova. (*c*) You receive light in the Earth reference frame emitted by a satellite 60,000 km away at $t = 0$, and 233 ms later receive light emitted by a spaceship 180,000 km away in the same direction as the satellite. (*d*) At $t = 0$, a pilot traveling at $0.75c_0$ relative to a star system receives signals from two planets A and B in that system. She then passes planet A (event 1) at $t = 450$ s and 90 s after that passes planet B (event 2). ●
28. Calculate the Lorentz factor for an object moving relative to Earth at (*a*) 60 mi/h, (*b*) 0.34 km/s (speed of sound in air), (*c*) 28×10^3 km/h (orbital speed of the International Space Station), (*d*) $0.1c_0$, (*e*) $0.3c_0$, and (*f*) $0.995c_0$. Express your answers as "1 + correction." ●●
29. You measure the period of light clock A to be T as it moves relative to you with a speed $0 < v_A < 0.5c_0$. You measure the period of an identical light clock (clock B) to be $3T$ as it moves relative to you with speed $v_B = 2v_A$. Determine numerical values for the speeds of each clock in your reference frame. ●●
30. A space station sounds an alert signal at time intervals of 1.00 h. Spaceships A and B pass the station, both moving at $0.400c_0$ relative to the station but in opposite directions. How long is the time interval between signals (*a*) according to an observer on A and (*b*) according to an observer on B? (*c*) At what speed must A move relative to the station in order to measure a time interval of 2.00 h between signals? ●●
31. A certain muon detector counts 600 muons per hour at an altitude of 1900 m and 380 muons per hour at sea level. Given that the muon half-life at rest is 1.5×10^{-6} s, determine the speed of the muons relative to Earth, assuming they all have the same speed. ●●
32. Planets A and B are 10 light years apart in the reference frame of planet A. (One light year is the distance light travels in one year.) A deep-space probe is launched from A, and 5 y later (in reference frame A) a similar probe is launched from B. Does a reference frame exist in which these two events (*a*) are simultaneous and (*b*) occur at the same position? (*c*) Compute, if possible, the proper time interval between the events? (*d*) How do your answers to parts *a*–*c* change if the planets are (in reference frame A) 5 light years apart and the time interval between launch from A and launch from B is 10 y? ●●
33. Section 14.3 describes how the number of muons reaching Earth's surface is greater than the number expected based on the muon half-life of 1.5×10^{-6} s. How fast, relative to Earth, must muons be moving in order for one of every million muons to pass through a distance equal to Earth's diameter without decaying? ●●

34. One cosmonaut orbited Earth for 437 days, as measured by Earth clocks. His speed of orbit was 7700 m/s relative to Earth during this time interval. Assume two clocks were synchronized on Earth, and one went into space with the cosmonaut while the other remained on Earth. You are interested in knowing by how much the clock readings disagree at the end of the 437 days. What are some problems with applying Eq. 14.13 to this situation? What information other than the cosmonaut's speed relative to Earth might you need to know? If you used Eq. 14.13, would you expect the clock readings to be very different from each other? •••

14.6 Length contraction

35. A cosmic ray traveling at $0.400c_0$ relative to Earth passes observer A (event 1) and then a short time interval later passes observer B (event 2). The observers are at rest, 8.00 km apart in the Earth reference frame. What are (*a*) the proper length and (*b*) the proper time interval between these events? •
36. An elementary particle is launched from Earth toward the Regulus system, 77.5 light years distant. At what speed relative to Earth must this particle travel to make this trip in 10 y in the reference frame of the particle? •
37. Spaceships A and B pass a space station at the same instant, the two ships moving in opposite directions at the same speed of $0.600c_0$ relative to the station. What is the Lorentz factor associated with the relative motion of the ships? •
38. Two elementary particles pass each other moving in opposite directions, each moving at speed $0.800c_0$ relative to Earth. What is the speed of one particle relative to the other? •
39. The radius of Earth is 6370 km in the Earth reference frame. In the reference frame of a cosmic ray moving at $0.800c_0$ relative to Earth, how wide does Earth seem (*a*) along the flight direction and (*b*) perpendicular to the flight direction? •
40. Show that the Lorentz transformation equations (Eqs. 14.29–14.32) reduce to the Galilean transformation equations in the limit $v_{AB} \ll c_0$. ••
41. An elementary particle moving away from Earth reaches its destination after two weeks (in the reference frame of the particle) traveling at $0.9990c_0$ relative to Earth. How far has it traveled in (*a*) its reference frame and (*b*) the Earth reference frame? ••
42. Describe the shape of the Moon as measured by an observer in a reference frame traveling past the Moon at a relative speed of (*a*) 1000 m/s, (*b*) $0.50c_0$, and (*c*) $0.95c_0$. ••
43. When at rest in the Earth reference frame, the delta-wing spaceship in Figure P14.43 is 7.00 m long and has a wingspan of 8.00 m. (*a*) What is the opening angle α of its wings? (*b*) If the same ship is moving forward at $0.700c_0$ relative to Earth, what does an observer on Earth measure for the plane length, wingspan, and opening angle α? ••

Figure P14.43



44. Standing at rest in the Earth reference frame, you observe two events, also at rest in that reference frame, occurring at these coordinates: event 1: $x_1 = 10$ km, $y_1 = 5.0$ km, $z_1 = 0$, $t_1 = 20\ \mu$s; event 2: $x_2 = 30$ km, $y_2 = 5.0$ km, $z_2 = 0$, $t_2 = 30\ \mu$s. At what speed and in what direction must your friend travel relative to Earth so as to observe these events as being simultaneous? ••
45. Use the Lorentz transformation equations (Eq. 14.29–14.32) to prove that the space-time interval s^2 between two events is *Lorentz-invariant*, which means it has the same value for all possible inertial reference frames. ••
46. An elementary particle travels at $0.840c_0$ across a solar system that has a diameter of 8.14×10^{12} m (both measurements in the reference frame S of the solar system). (*a*) What value does an observer in reference frame S measure for the time interval needed for the particle to cross the solar system? (*b*) What time interval is needed in the reference frame P of the particle? (*c*) What is the proper length of the diameter? (*d*) What is the proper time interval for the particle's trip across the system? (*e*) What is the diameter of the solar system in reference frame P? ••
47. A space colony defines the origin of a coordinate system in reference frame C, and you are at rest in this reference frame at position $x = +3.000 \times 10^5$ km. A ship passes the colony moving in the positive x direction at $0.482c_0$ in reference frame C. By prearrangement, observers on the ship (reference frame S) and on the colony use this event (event 0) to define $x = 0$ and $t = 0$ in both reference frames. Just as the ship passes, the colonists send out a light pulse toward you (event 1), and you transmit a reply pulse (event 2) immediately upon receipt. (*a*) At what position in reference frame S do observers see the colonists' pulse originate? (*b*) At what instant does the pulse originate according to these observers? (*c*) At what position in reference frame S do the observers see your reply pulse originate? (*d*) At what instant does the reply pulse originate according to observers on the ship? ••
48. Observer O at the origin of a coordinate system is at rest relative to two equidistant space stations located at $x = +3.00 \times 10^6$ km (station A) and $x = -3.00 \times 10^6$ km (station B) on the x axis. In reference frame O, station A sends out a light pulse at $t = 0$ (event 1) and station B also sends out a light pulse at $t = 0$ (event 2). Observer C moves relative to O with velocity $0.600c_0$ in the positive x direction, and observer D moves relative to O with velocity $0.600c_0$ in the negative x direction. What are the displacement from event 1 to event 2, and the time interval between events 1 and 2, according to (*a*) observer C and (*b*) observer D? ••
49. A spaceship travels at $0.610c_0$ away from Earth. When the ship is 3.47×10^{11} m away in the Earth reference frame, the ship clock is set to $t = 0$ and a message (light signal) is sent to its ground crew on Earth. When this message is received, the ground crew immediately sends a reply (light signal) to the ship. The ground crew adjust their clocks to specify $t = 0$ as the time the message was sent from the ship. (*a*) What is the reading on the ground crew's clock at the instant the ship receives the reply signal? (*b*) According to the ground crew, how far from

Earth is the ship when it receives the reply? (*c*) What is the reading on the ship's clock at the instant the reply reaches the ship? •••

50. According to an observer at rest in the Earth reference frame, ship A travels in one direction at speed $0.862c_0$ while ship B moves in the opposite direction at $0.717c_0$. Ship A sends out a shuttle module M that travels to ship B at speed $0.525c_0$ relative to A. For every 1.00 s that passes on M, how many seconds pass according to (*a*) a clock on A, (*b*) a clock on B, and (*c*) a clock held by the observer on Earth? •••

51. Two asteroid clusters at rest with respect to each other are 3.00×10^9 m apart, and both measure 6.00×10^8 m across in the reference frame of the clusters. A pilot in a spaceship moving at $0.900c_0$ relative to the cluster reference frame is trying to pass between the two clusters. To an observer who is stationary in the reference frame of the clusters, the ship just barely misses the corners of the clusters as shown in Figure P14.51. If a line were drawn between the centers of the two clusters, what would be the angle between that line and the ship's path in (*a*) the reference frame of the clusters and (*b*) the reference frame of the ship? •••

Figure P14.51

14.7 Conservation of momentum

52. Determine the magnitude of the momentum of a muon in a reference frame in which the muon moves with speed $0.500c_0$. The mass of a muon is 207 times the mass of an electron. •

53. An electron accelerates from $0.700c_0$ to $0.900c_0$ in the Earth reference frame. In this reference frame, by what factor do (*a*) its mass and (*b*) its inertia increase? •

54. (*a*) What is the magnitude of the momentum of an electron in a reference frame in which it is moving at $0.500c_0$? (*b*) At what speed must the electron move in a reference frame in which it has twice the momentum you calculated in part *a*? ••

55. Object A, mass 4.24×10^5 kg, is at rest in reference frame A, and object B, mass 7.71×10^4 kg, moves at $0.875c_0$ in this reference frame. (*a*) What does an observer at rest in A measure for the momentum of B? (*b*) What does an observer at rest with respect to object B measure for the momentum of A? (*c*) A reference frame C moves at $0.300c_0$ relative to reference frame A and moves in the same direction as object B. What are the momenta of objects A and B as measured by an observer at rest in reference frame C? ••

56. A uniform 200-kg cube that has a volume of 8.00 m^3 (measured when the cube is at rest in the Earth reference frame) travels perpendicular to a pair of its faces at $0.672c_0$ relative to Earth. (*a*) What is the mass density of the cube according to an observer at rest on Earth? (*b*) How fast (in the Earth reference frame) must a 100-kg object travel in the opposite direction to stop this cube in a collision? ••

57. Muons are formed 10.0 km above Earth's surface. What magnitude of momentum (in the Earth reference frame) must they have immediately after formation in order for only one of every 10,000 of them to reach the ground? The mass of a muon is 207 times the mass of an electron. ••

58. Two chunks of rock, each having a mass of 1.00 kg, collide in space. Just before the collision, an observer at rest in the reference frame of a nearby star determines that rock A is moving toward the star at $0.500c_0$ and rock B is moving away from the star at $0.300c_0$. If the rocks stick together after the collision, what are the direction and magnitude of their velocity (in the reference frame of the star) immediately after the collision? ••

59. In the Earth reference frame, a 150-kg probe travels at $0.860c_0$ while a 250-kg probe travels at $0.355c_0$ in the opposite direction. What are the velocities of the probes in the zero-momentum reference frame? •••

14.8 Conservation of energy

60. At what speed must a particle move in your reference frame so that its kinetic energy is equal to its internal energy? •

61. Particles A, B, and C each have mass *m*, and their energies are $E_A = E$, $E_B = 2E$, and $E_C = 3E$. Rank the particles, largest first, in order of (*a*) Lorentz factor, (*b*) kinetic energy, (*c*) speed, and (*d*) magnitude of momentum. •

62. What is the internal energy of an electron moving at $0.750c_0$ in the Earth reference frame? •

63. Uranium-238 decays to thorium and helium according to the reaction $^{238}\text{U} \rightarrow {}^{234}\text{Th} + {}^{4}\text{He}$. How much energy is released when 1.00 kg of uranium-238 decays? Compare this amount with the energy released when 1.00 kg of coal is burned (approximately 30 MJ). The atomic masses are $m_U = 395.292632 \times 10^{-27}$ kg, $m_{Th} = 388.638541 \times 10^{-27}$ kg, and $m_{He} = 6.646479 \times 10^{-27}$ kg. ••

64. Assume that 437 days is a reasonable limit for how long a human can endure constant-velocity space travel. Proxima Centauri, the star closest to our Sun, is 4.24 light years away from Earth. If you wanted to fly to Proxima Centauri within the 437-day limit in a rocket of mass 2.00×10^6 kg, how much energy would be required to accelerate the rocket to the necessary speed in the Earth reference frame? For this rough estimate, ignore the energy required to stop, and disregard the hundreds of days required at each end of the journey for acceleration.

Compare your answer with 0.6×10^{21} J, the yearly worldwide energy consumption predicted for 2015. ••

65. A particle of mass m_{orig}, initially at rest in the Earth reference frame, decays into two particles 1 and 2 that have masses m_1 and m_2, respectively. Use conservation of energy, conservation of momentum, and Eq. 14.57, $E^2 - (c_0 p)^2 = (mc_0^2)^2$, to calculate the energy and momentum magnitude of particle 1 in the Earth reference frame in terms of m_{orig}, m_1, m_2, and c_0. ••

66. Which of the following forms of energy contribute to the mass of a gas molecule: (*a*) energy due to the molecule rotating about its center of mass, (*b*) energy due to compression of atoms in the molecule, (*c*) energy due to the molecule's translational motion relative to Earth? ••

67. At the Large Hadron Collider in Switzerland, two high-energy protons collide to create new particles. Prior to collision, each proton is accelerated to an energy of 7000 GeV in the Earth reference frame. (*a*) What is the speed of each proton? (*b*) What is the maximum mass possible for any particle created in the collision? The proton mass is 938 MeV/c_0^2; 1 GeV = 1000 MeV. ••

68. An electron e^- and positron e^+ moving at the same speed in the Earth reference frame collide head-on and produce a proton p and an antiproton $\bar{p}$. The electron and positron have the same mass. The proton and antiproton also have the same mass. The mass of the proton is 1836.15 times the mass of the electron. Calculate, in the Earth reference frame, the minimum value possible for the ratio of the electron's kinetic energy to its internal energy in order to have the reaction $e^- + e^+ \rightarrow p + \bar{p}$ take place. ••

69. Antihydrogen is the only antimatter element that has been produced in the laboratory, albeit just a few atoms at a time. Each antihydrogen atom consists of a positron in orbit around an antiproton and has the same atomic mass as hydrogen. If an antihydrogen atom collides with a hydrogen atom, they annihilate each other and create gamma radiation. (*a*) What minimum amount of energy is released in this process? (*b*) If this energy could be harnessed in a matter-antimatter automobile engine, how far could a car travel on 10 mg each of antihydrogen and hydrogen? At highway speeds, a typical automobile expends about 2.5×10^3 J per meter. •••

Additional Problems

70. Galaxy A moves away from galaxy B at $0.600c_0$ relative to B. A spaceship leaves a planet in galaxy A traveling at $0.500c_0$ relative to galaxy A. If the direction in which the ship travels is the same as the direction in which A is moving away from B, what do observers in B measure for the ship's speed? •

71. A tree that is 32.6 m tall leans 26.0° from the vertical in the Earth reference frame. How tall is the tree, and at what angle does it lean, in the reference frame of a cosmic ray muon moving parallel to the tree at a speed of $0.382c_0$ relative to Earth? •

72. Consider a searchlight on the ground that casts a spot on a cloud 1000 m overhead. If the searchlight is rotated rapidly—say, 30° in 1 μs—how fast does the spot move in the Earth reference frame? Is this a violation of special relativity? ••

73. Two events occur at different locations on Earth and are simultaneous in the reference frame of an observer standing on Earth halfway between the events. Are these events simultaneous in any other inertial reference frame? ••

74. Pilot A is seated in the middle of a ship that has a proper length of 250 m, and pilot B is seated in the middle of an identical ship. Pilot B passes A at a speed that A measures to be $0.580c_0$. How long does it take B's ship to pass pilot A (*a*) according to A and (*b*) according to B? How long does it take A's ship to pass pilot B (*c*) according to A and (*d*) according to B? ••

75. Relative to Earth, spaceship A travels at $0.732c_0$ away from Earth, and spaceship B travels at $0.914c_0$ toward Earth along the same straight line. (*a*) How fast does A move according to an observer aboard B? (*b*) At $t = 0$ the two ships are separated by 4.5×10^{10} m in the Earth reference frame. At what instant t do they pass each other according to an observer at rest on Earth? ••

76. A proton p_1 moving in the Earth reference frame collides with a proton p_2 that is at rest in that reference frame. The collision creates a particle that has mass m and an internal energy 40 times the internal energy of a proton: $mc_0^2 = 40m_p c_0^2$. The velocity of this new particle in the Earth reference frame is not given. What is the ratio of the energy of p_1 to its internal energy in the Earth reference frame? (Hint: First analyze the collision in the zero-momentum reference frame in which p_1 and p_2 are both in motion, moving in opposite directions at the same initial speed.) ••

77. You are consulting for an episode of *Stars Wars, Part XVI*. As this episode opens, starship Orion zooms past a space station at $t = 0$ ship's time, traveling at a constant $0.6000c_0$ relative to the station. When the Orion's clock reads $t = 1000$ s, her sensors detect a hostile battle cruiser. Based on its observed speed, the cruiser is calculated to be 8.00×10^7 km dead ahead and closing in, traveling on a direct line toward the Orion and the space station at a speed of $0.8000c_0$ relative to the Orion. The Orion immediately sends a light signal to the station warning the crew to evacuate. Your boss says to assume that evacuating the station requires 45.0 min measured in the reference frame of the station, and wants to know if a rewrite is required. ••• CR

78. Your boss wants you to construct a spring that, when compressed, experiences a mass increase of 1/10,000 of 1%. He has no idea whether this is possible, but you decide to write a report listing desirable parameters (spring mass, spring constant, load mass), discussing problems you might encounter in attempting to make such a spring, and considering whether or not the conventional spring equations apply. ••• CR

79. The Lorentz Cup spaceship race is won by the pilot who can travel 1.00×10^9 m in the shortest time interval. The rules state that the start and finish lines must be 10^9 m apart in the ships' reference frame, but the time interval is measured by an observer at rest in the Earth reference frame. There are many racing speeds you might try, such as $0.420c_0$ and $0.980c_0$ relative to the Earth reference frame, but trying a few combinations randomly makes you wonder if there is a better way than trial and error to decide on a strategy for this race. ••• CR

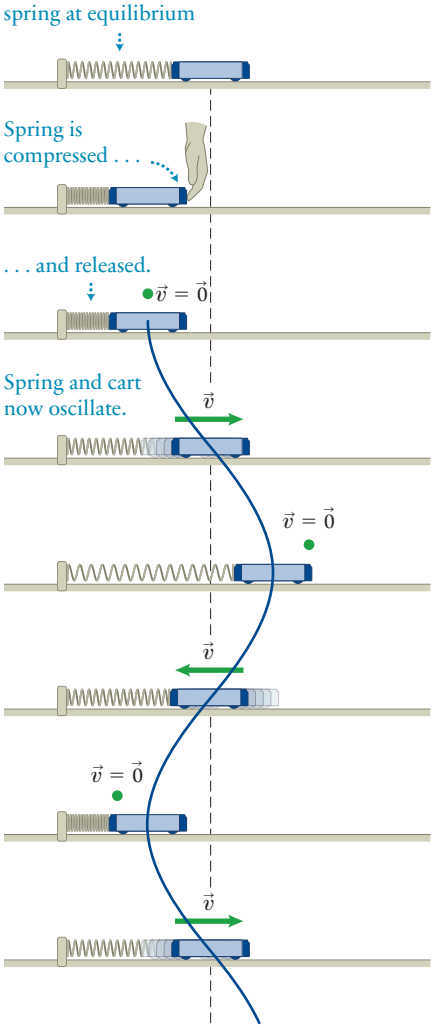
Periodic Motion

CONCEPTS

15.1 Periodic motion and energy
15.2 Simple harmonic motion
15.3 Fourier's theorem
15.4 Restoring forces in simple harmonic motion

QUANTITATIVE TOOLS

15.5 Energy of a simple harmonic oscillator
15.6 Simple harmonic motion and springs
15.7 Restoring torques
15.8 Damped oscillations



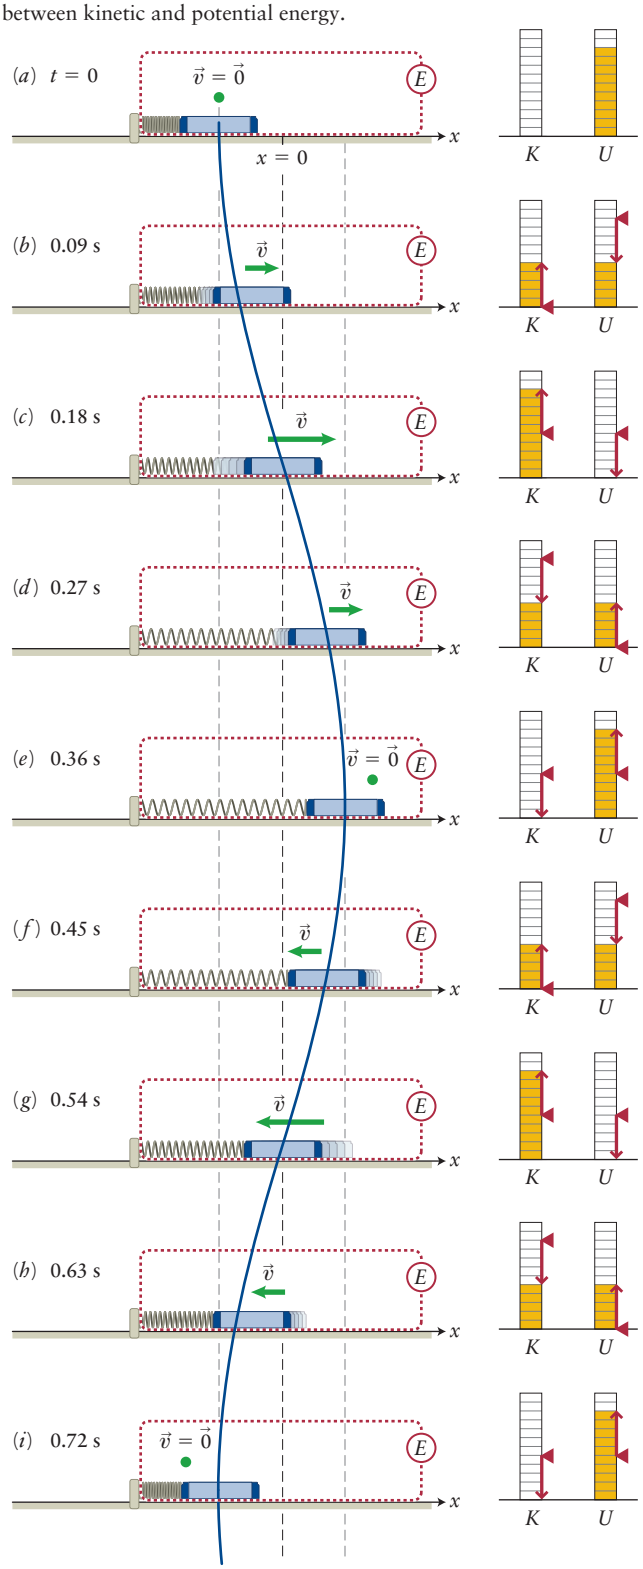
Any motion that repeats itself at regular time intervals is called **periodic motion.** The motion of, say, the Moon revolving around Earth or Earth revolving around the Sun is one type of familiar periodic motion, as is the rotation of the hands of a clock. In this chapter, we are interested in a particular type of periodic motion—namely, back-and-forth periodic motion. Such motion, called either **vibration** or **oscillation** (the two words mean the same thing), is common at all scales in the universe. A rocking chair, a swing, the pendulum of a grandfather clock, the strings on a guitar, the wings of a mosquito all oscillate. At the atomic level, atoms oscillate inside solids. At the cosmic level, the entire universe may oscillate in an ever-repeating cycle of expansion and contraction. The physical natures of these periodic motions are very different from one another, and yet they are all closely related and their mathematical descriptions are always of the same form, differing only in the quantities involved.

In this chapter, we first develop a model for the simplest type of oscillation, called *simple harmonic motion*, and relate it to a periodic motion we are already familiar with: rotational motion. Then we show that any oscillation can be described in terms of simple harmonic motions. After presenting a number of examples, we discuss the effects of energy dissipation during oscillations.

15.1 Periodic motion and energy

Figure 15.1 shows the periodic motion of a spring-cart system. The system, initially at rest, is compressed and then released from rest. After being released, the cart oscillates back and forth along the low-friction track, alternately compressing and stretching the spring. (Ignore friction.)

Figure 15.1 Compressing and releasing the spring cause the cart to oscillate back and forth on the track.



15.1 (*a*) List the forces exerted on the spring-cart system of Figure 15.1 right after it is released, and draw a free-body diagram for each object in the system. (*b*) Which of these forces do work on the system as it oscillates? (*c*) As the hand pushes on the cart and compresses the spring, is the work done by the cart on the spring positive, negative, or zero? (*d*) How does the work done by the cart on the spring compare with the work done by the spring on the cart?

To understand why the motion of the cart in Figure 15.1 is periodic and why the cart doesn't simply return to its initial position and remain there, let us look at the mechanical energy in the cart-spring system. As the spring is compressed by the hand, elastic potential energy is stored in the system. Just before the cart is released, the system is at rest, so the mechanical energy of the system consists entirely of potential energy (**Figure 15.2***a*). After the cart is released, the spring-cart system is closed—none of the forces exerted on it does any work on it—and so the energy of the system must remain constant.

In order to analyze the system's energy changes in more detail, we choose a $+x$ axis that points in the initial direction of motion of the cart and that has its origin at the center of the cart's equilibrium position. As the expanding spring speeds up the cart in the positive x direction, the kinetic energy increases and the potential energy decreases (Figure 15.2*b*). When the cart reaches the equilibrium position at $x = 0$, the potential energy is zero (Figure 15.2*c*). The cart, however, does not stop at this position because its kinetic energy is not zero. The cart therefore overshoots the equilibrium position and begins stretching the spring. As the spring stretches, it exerts on the cart a restoring force that slows the cart down and converts kinetic

CONCEPTS

Figure 15.2 Periodic motion is the result of a continuous exchange between kinetic and potential energy.

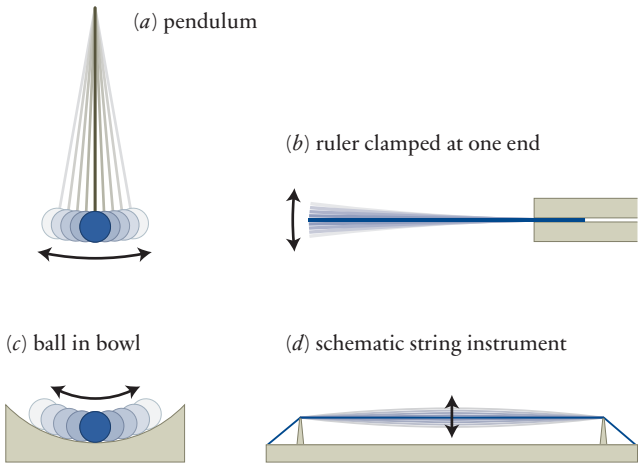
energy back to elastic potential energy (Figure 15.2*d*). This continues until the kinetic energy falls to zero, at which point the cart reverses its direction of travel (Figure 15.2*e*). The potential energy is converted back to kinetic energy (Figure 15.2*f*), and the cart again returns to the equilibrium position, this time traveling leftward (Figure 15.2*g*). The potential energy is zero again, but with the cart's kinetic energy being nonzero, it overshoots the equilibrium position once again. Provided no energy is dissipated, the system returns to its initial state (compare Figures 15.2*a* and 15.2*i*). A new cycle begins, and the cart repeats its back-and-forth motion.

15.2 (*a*) In Figure 15.2*e*, the cart's displacement from the equilibrium position is maximum. Is the x component of the cart's acceleration at that instant positive, negative, or zero? (*b*) At which instant(s) in Figure 15.2 is the magnitude of the cart's acceleration greatest? At which instant(s) is it smallest? (Use the blue position curve to answer these questions.)

The time interval it takes to complete a full cycle of the motion is the *period* T (see Section 11.1). For the motion shown in Figure 15.2 the period is equal to the time elapsed between (*a*) and (*i*): $T = 0.72$ s. The inverse of the period, called the **frequency** of the motion, $f = 1/T$, gives the number of cycles completed per second. In Figure 15.2, $f = 1/(0.72\text{ s}) = 1.4\text{ s}^{-1}$ and so the cart completes 1.4 cycles each second.

The magnitude of the cart's maximum displacement from the equilibrium position is called the **amplitude** A of the periodic motion. The amplitude is related to the mechanical energy of the system. In Figure 15.2, for example, the greater the initial compression of the spring, the greater the amplitude and the greater the initial potential energy.

In practice, periodic motion in mechanical systems does not continue indefinitely because some energy is always dissipated (friction in the cart's bearings, air resistance, heating of the spring). This dying out of periodic motion due to dissipation of energy is called *damping*. Initially, we shall ignore damping and, with this simplification, we find that:



Periodic motion is characterized by a continuous conversion between potential and kinetic energy in a closed system.

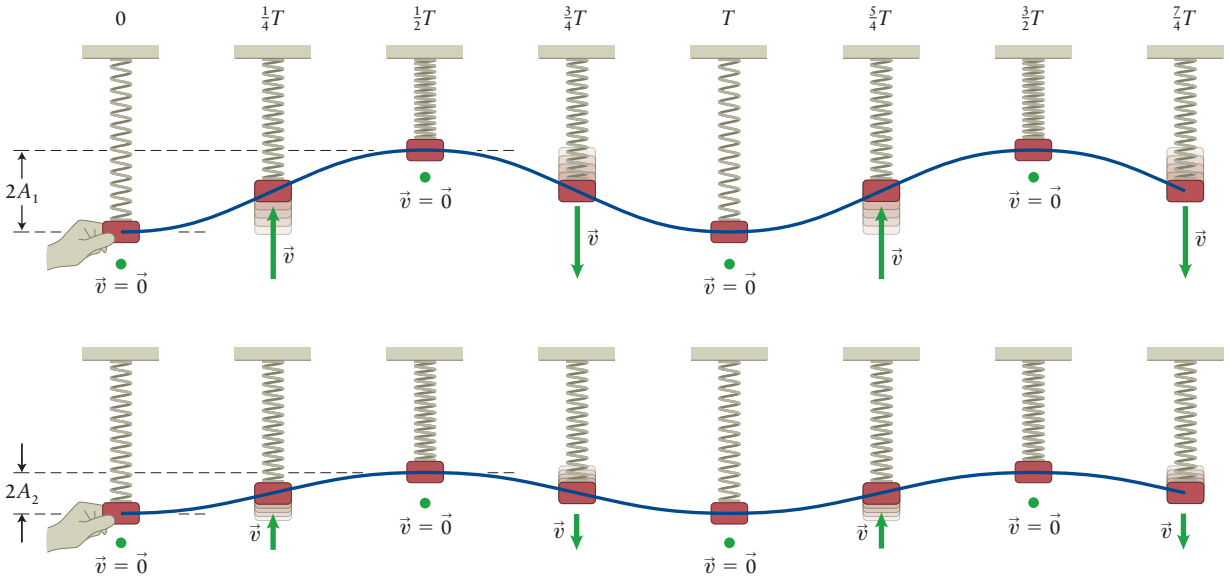
All systems that exhibit this behavior have one common feature: a restoring interaction that tends to return the system to equilibrium. Some examples are illustrated in **Figure 15.3**. Each of these systems executes periodic motion when disturbed from its equilibrium position, and in each case the amplitude of the motion is a measure of the mechanical energy of the system.

15.3 For each system in Figure 15.3, identify (*a*) the restoring force and (*b*) the type of potential energy associated with the motion.

CONCEPTS

Figure 15.3 Examples of oscillating systems.

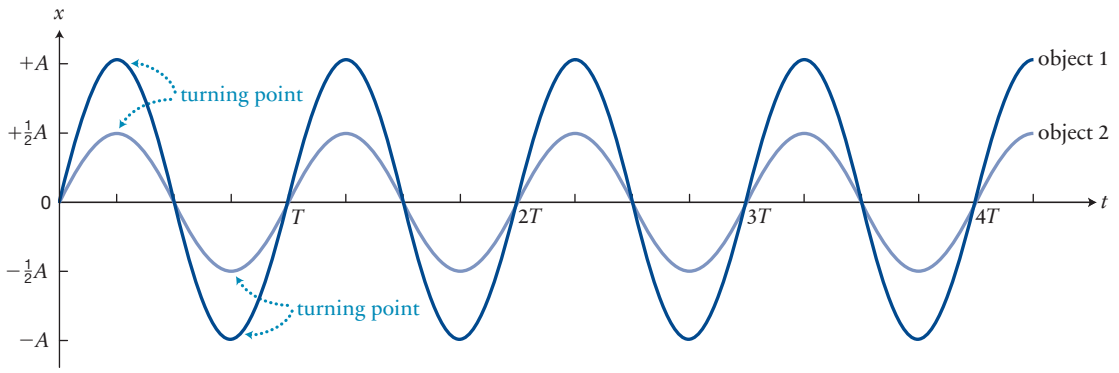
15.2 Simple harmonic motion



Measuring the period of any oscillating system reveals a surprising fact: When the amplitude of the motion is not too great, the period is independent of the amplitude. For example, an object suspended from a spring has a fixed period of oscillation regardless of its amplitude (**Figure 15.4**). The period of a pendulum, too, is independent of the amplitude of its swing, which is why pendulums are used to regulate the movement of mechanical clocks. Likewise, when you pluck a guitar string, the pitch of the sound, which is determined by the string's period of oscillation, is the same regardless of how far back you pull the string.

A system that exhibits equal periods for all amplitudes is called *isochronous*. Provided their amplitudes are not too great, all the systems shown in Figure 15.3 are isochronous. Individual systems have different periods that are determined by the properties of the system, but any given system has a period that is essentially independent of amplitude.

The graph of displacement versus time for an isochronous oscillating system is shown in **Figure 15.5**. The $x(t)$ curves for an isochronous oscillation have the shape of sine functions. For this reason they are referred to as *sinusoidal curves*. Any periodic motion that yields a sinusoidal $x(t)$ curve is called **simple harmonic motion,** and a system that executes such motion is called a *simple harmonic oscillator*. For small amplitudes, all the systems shown in Figure 15.3 yield this type of $x(t)$ curve, and so all are examples of simple harmonic motion. The motion is called harmonic because in musical instruments harmonic motion is responsible for the sound emitted by the instruments.



The fact that simple harmonic motion is isochronous allows us to draw some important conclusions. Consider, for example, the two isochronous $x(t)$ curves in Figure 15.5, one with twice the amplitude of the other. These could be the curves of two identical pendulums or any other of the systems shown in Figure 15.3, with one oscillating object moving twice as far out as the other. In one period, object 1 always covers twice the distance that object 2 covers. Because the periods are the same, the velocity of object 1 must always be twice as great as that of object 2 at the same instant in the periodic motion. Neither motion has constant velocity or constant acceleration—the velocities and accelerations change constantly. However, in order for the velocity of object 1 always to be twice

Figure 15.4 The oscillation of an object suspended from a spring is isochronous: The period T does not depend on the amplitude of the oscillation.

CONCEPTS

Figure 15.5 Positions-versus-time graphs for two isochronous objects.

that of object 2, the acceleration of object 1 must, at each instant, be twice as great as the acceleration of object 1.

As you saw in Checkpoint 15.2, the acceleration is greatest when the displacement from the equilibrium position is greatest (that is, at the *turning points*, which are the positions where the object turns around). This tells us that the acceleration of object 1 at its turning point $x_1 = A$ is twice as great as that of object 2 at its turning point $x_2 = \frac{1}{2}A$. Given that the two objects are identical, we conclude that the acceleration of an isochronous object is proportional to the displacement from the equilibrium position. Because the acceleration of an object is proportional to the vector sum of the forces exerted on it, this tells us that the restoring force exerted on the oscillating object is also proportional to the displacement from the equilibrium position. We already know that springs exert linear restoring forces (Hooke's law, Section 8.9). The observation that all systems in Figure 15.3 are isochronous tells us, then, that the restoring forces in all these systems must also be linearly proportional to the displacement from the equilibrium position.

CONCEPTS

An object executing simple harmonic motion is subject to a linear restoring force that tends to return the object to its equilibrium position and is linearly proportional to the object's displacement from its equilibrium position.

15.4 Suppose the spring in Figure 15.1 is compressed twice as much. (*a*) By how much does the mechanical energy of the spring-cart system increase? (*b*) What is the relationship between the amplitude of the oscillation and the mechanical energy in the oscillating system?

Simple harmonic motion is closely related to a periodic motion we have already studied: circular motion at constant speed. To see how the two are related, imagine projecting the shadow of a small sphere in circular motion at constant speed onto a screen perpendicular to the plane of the motion (**Figures 15.6** and **15.7**). While the sphere sweeps out a circular trajectory, its shadow oscillates up and down on the screen. The position of the shadow at any instant is given by the vertical component of the sphere's position vector at that instant. If the sphere begins on the horizontal axis and moves with a constant rotational speed ω, the angle ϕ between the sphere's position vector and the horizontal axis grows steadily with time: $\phi = \omega t$. The position of the sphere's shadow on the screen is then described by $A \sin(\omega t)$, where A is the radius of the sphere's trajectory. Because it is described by a sinusoidal function, the projection of circular motion at constant speed is simple harmonic motion.

The correspondence between circular motion at constant speed and simple harmonic motion can be demonstrated experimentally by projecting the shadows of an object in simple harmonic motion and an object in circular motion at constant speed on a screen, as in Figure 15.7. If the rotational speed is adjusted so that its period equals that of the oscillation, the shadows of the two objects move synchronously.

15.5 What are (*a*) the direction of the velocity of the shadow on the screen in Figure 15.6 and (*b*) the direction of the shadow's acceleration?

Figure 15.6 If we project the shadow of a ball moving in a circle at constant speed onto a screen perpendicular to the plane of the motion, the shadow moves up and down in simple harmonic motion.
